1492, and immediately colonized. Porto Rico and Jamaica were colonized in 1509; Cuba in 1511. On the mainland a Spanish settlement was effected in Colombia (New Granada) in 1511. Mexico was conquered 1519–21; Ecuador, Venezuela, New Granada, Peru and Chile were occupied and subdued between 1524 and 1541; and Spain was raised to the first rank among the colonizing powers of Europe. The Spaniards regarded their new possessions in various respects. Some, animated by a zeal for religion, considered the conversion of the natives as the great end which Heaven had assigned to them. Others were inspired by the love of glory or the passion for gain and scrupled at no means by which it was possible to gratify their wishes. Owing to the degraded character of many of the first colonists, who were often mere adventurers and released criminals, the first settlements suffered much from internal strife and confusion. After many dissensions the government of the colonies, in its fundamental traits, was settled in 1532, during the reign of the Emperor Charles V. A council of the Indies in Europe, viceroys, at first two, afterward four, together with eight independent captains-general in America, were the heads of the administration. Cities were founded, at first along the coasts, for the sake of commerce and as military posts; afterward also in the interior, especially in the vicinity of the mines; as Vera Cruz, Cumana, Porto Bello, Carthagena, Valencia, Caracas; Acapulco and Panamá on the coast of the Pacific; Lima, Concepcion and Buenos Aires. The whole ecclesiastical discipline of the mother country was transferred to the colonies, except that in them the Church was much more independent of the king. The intercourse with Spain was confined at first to the single port of Seville, afterward to that of Cadiz, from which two squadrons started annually. Thus, although commerce was not expressly granted by law to a society, it remained nevertheless entirely in the hands of a few individuals. Spain took possession of the Philippine Islands in 1565 and a regular intercourse was maintained from 1572 by the South Sea galleons between Acapulco and Manila; but owing to the great restrictions on commerce those islands, notwithstanding their advantageous situation, were an expense to the Crown. Spain proved to be the foremost of the colonizing powers of Europe in respect to the formation of new states; the most unfortunate of all in regard to the retention of her possessions. The causes of the loss of her colonies differed from those which prevailed in the case of the Portuguese. European wars and the decline of her home power were the most important, but they did not so often lead to the colonies falling under other powers, as in the case of Portugal. They more frequently became the occasion of revolt and the opportunity for declarations of independence on the part of the colonies themselves. Thus were formed the republics of Mexico, of Central America, of Venezuela, New Granada, or Colombia, Ecuador, Peru, Bolivia, Chile, etc.; but as the weak government of the mother country served to promote this early defection, few of the states formed in this unfortunate school have yet attained the repose of settled government. An insurrection began in Cuba in 1895, and after Spain had in vain endeavored to suppress it the United States interfered. War followed, with the result that after a brief struggle not only Cuba, but also Porto Rico and the Philippine Islands were lost to Spain. See SPAIN.

The Netherlands.— The Dutch, during the struggle for independence, first became the formidable rivals of the Portuguese, then subject to the Spanish yoke. They had already for some time carried on the trade in East India merchandise between Lisbon and the rest of Europe, but their intercourse with Lisbon was prohibited by Philip II in 1584. The prohibition was revived in 1594 with the utmost severity, and a number of Dutch vessels in the harbor were seized. Excluded from the European trade in the productions of India, they resolved to import directly from India the articles which were refused to them in Europe. Companies were formed, which were united into one by a charter granted 20 March 1602 to the Dutch East India Company, established in 1595. This charter, which was renewed afterward at different times, conferred not only the monopoly of the East India trade, but also sovereign powers over the conquests which the company should make, and the colonies which it should establish in India. An entirely new colonial policy was thus introduced, which, instead of political or ecclesiastical aggrandizement, contemplated mercantile advantage as its main object. The Dutch colonies in the East Indies were thus commercial colonies; and the islands of the Malay Archipelago, being more easily defended than the continent of India, became the principal seat of the Dutch power. This was undoubtedly the chief cause of their colonies being so long in a flourishing condition, as they required only the dominion of the sea to maintain them. In 1619 the newly built Batavia was made the capital of the Dutch East Indies. About the middle of the 17th century the power of the Dutch reached its highest point. They effected the establishment of a colony at the Cape of Good Hope in 1652, which afforded an excellent bulwark for their East India possessions, and took Ceylon from the Portuguese, after a long and sanguinary struggle in 1658. All the Dutch colonies in the East Indies were under the governor-general of Batavia. In 1621 the Dutch also established a West India Company, which at first made extensive conquests in Brazil, but soon lost them entirely (1624–62). Their settlements on some of the smaller West India Islands, as San Eustatia, Curaçoa, Saba and San Martin (1632–49), were more permanent. On the continent Surinam, Paramaribo, Essequibo and Berbice were in the hands of the Dutch in 1667. In North America the Netherlands held the valley of the Hudson and pushed south at the expense of the Swedes, winning the present States of New Jersey and Delaware, only to lose them to England. The decline of the Dutch colonial power, partly caused by European wars and partly by the successful rivalry of the English, continued from the end of the 17th century till the French Revolution. On the recovery of its independence, the commerce and the colonial importance of Holland somewhat revived and though many of her colonies were lost the value of the remainder was enhanced by improved administration. The Dutch still possess numerous colonial possessions in the East Indies, including

Java, Sumatra, parts of Borneo, the Moluccas and part of New Guinea; several small islands in the West Indies and Surinam. See NETHERLANDS.

Great Britain.— No colonizing power has had a career of such uniform prosperity as Great Britain. The freedom of her institutions and the practical enterprise and self-reliance of her people peculiarly fitted her for the work of colonization and it has steadily advanced with her equally in peace and in war. Her insular situation freeing her from the ambition of direct territorial aggrandizement and giving her the command of the seas enabled her in every war to strip her opponents of colonial possessions which were not unfrequently retained as the price of peace. The only break in a career of prosperity which has resulted in the formation of an empire greater in extent of territory and of population than any other known to history was the revolt of her American colonies, which resulted in the formation of a state destined ultimately to rival Great Britain herself in political and commercial importance and in the freedom of its institutions. This state, too, by the successful result of the war of 1898 with Spain, itself entered on a policy of colonial expansion.

The English made their appearance as a colonial power nearly at the same time with the Dutch, but at first with far inferior success. After many fruitless attempts to find a northeast or northwest passage to the East Indies, English vessels found their way round the Cape of Good Hope to the East Indies in 1591. In 1600 Elizabeth granted a charter to the East India Company. Its commerce with India, however, was not at first important. It established only single factories on the continent, and at the beginning of the 18th century the possessions of the English in the East were limited almost exclusively to Madras, Calcutta and Bencoolen. The ruin of the Mogul empire in India, which commenced in internal disturbances after the death of Aurungzebe (1707), and was completed by the incursions of Nadir Shah (1739), afforded the opportunity for the growth of British power, as the British and French were compelled to interfere in the contentions of the native princes and governors. The French, under Labourdonnais and Dupleix, appeared at first likely to maintain the superiority; but the British succeeded in acquiring the ascendency in the Carnatic; and in the middle of the 18th century they greatly extended their dominions under Clive. By the destruction of Pondicherry they secured their superiority on the coast of Coromandel; and the victory of Clive at Plassey, 23 June 1757, laid the foundation of their exclusive sovereignty in India. By the Treaty of Allahabad, 12 Aug. 1765, Bengal was surrendered to the British by the titular Great Mogul; and the fall of the empire of Mysore, the dominions of Hyder Ali and Tippoo Sahib, may be considered as completely establishing the British supremacy in India. The Mahrattas, with whom the British waged war at intervals from 1775 to 1818, and the Sikhs, subdued in 1849, were the last formidable enemies of the company. With the exception of a few dependent states the British territory now embraced nearly the whole of India, and this vast territory was still under the government of a chartered mercantile company, exercising many of the most important functions of an independent sovereignty. On the suppression of the Indian mutiny (1857–58) this state of things was deemed too hazardous to last and the government of India was transferred to the Crown by act of Parliament in 1858. Ceylon was first occupied in 1795–96.

The discoveries of the Cabots, following soon after the voyages of Columbus, gave the English Crown a claim to North America, which in the reign of Elizabeth led to colonization on a large scale. In 1606 James I divided the territory claimed by England into two parts — South Virginia, extending from Cape Fear to the Potomac; and North Virginia, from the mouth of the Hudson to Newfoundland. Two companies were formed for the colonization of America — the London Company, to which was granted South Virginia; and the Plymouth Company, to which was granted North Virginia. The region between the Potomac and the Hudson was neutral ground. The London Company in 1607 founded the commonwealth of Virginia by building Jamestown on the James River, so called in honor of the king. A House of Burgesses for the new colony met for the first time on 19 June 1619, and thus was constituted the beginning of representative government in the British colonies of America. In 1614 Capt. John Smith, having examined the coast from the Penobscot to Cape Cod, named the country here New England. The next permanent settlement on the North American coast was effected in this district by the body of Puritans, known as the Pilgrim Fathers, who sailed from England 6 Sept. 1620, in the *Mayflower,* and arrived 9 November in Massachusetts Bay. The government of this colony was that of a religious oligarchy. Another colony was established in New Hampshire in 1623, and in the same year Maine, which had previously been colonized by the French, received its first permanent English settlement. New Jersey was colonized in 1634. Connecticut was colonized in 1635 by emigrants from Massachusetts. Rhode Island was settled in 1636. Samuel Champlain, the French navigator, was the first European who entered the region now forming the State of New York (1609). In the same year Henry Hudson, an Englishman in the service of the Dutch East India Company, discovered the river to which his name has been given, where Dutch settlements were effected and gradually spread. The English, who claimed this territory as included in Cabot's discoveries, finally seized the Dutch colony of New Amsterdam by force in 1664, giving it the name of New York in honor of James, Duke of York (James II), to whom Charles II had made a grant of the province. In 1670 the charter of the Hudson's Bay Company was granted, by which ownership of all the regions whose waters discharge into Hudson Bay — a territory as large as the whole of Europe — was conferred on the company, the rights to which were only finally extinguished in 1869. In 1681 the territory west of the Delaware was granted to William Penn, who colonized it with Quakers, and founded Pennsylvania in 1682. The first settlement in Maryland was made in 1631 by a party from Virginia. In 1633 a colony of Roman Catholics arrived here from Great Britain. The country south of Virginia was permanently settled in 1670 by a party of

English colonists who landed at Port Royal and afterward removed to Charleston. The colony was called Carolina. Georgia, originally a part of Carolina, was granted by George II, after whom it was named, to a colony from England in 1732.

Colonies were early established in the West India Islands, including Barbados, half of Saint Christopher's (1625) and soon after many smaller islands. Yet the West India possessions did not become important as plantations until the sugarcane was introduced into Barbados in 1641 and into Jamaica in 1660. This island had been taken from the Spaniards in 1655. The cultivation of coffee was introduced into the West India Islands in 1732. Newfoundland was taken possession of by the English in 1583, and colonized in 1621 and 1633. Canada was surrendered by France to Great Britain at the Peace of Paris in 1763 (see section on French colonies below). In 1764 began the dispute between Great Britain and its North American colonies, on the question whether the former had the right to impose taxes on the colonies when they were not represented in the British Parliament; and on 19 April 1775 commenced the war which terminated with the acknowledgment of the independence of the 13 provinces. Though the United States thus entered on their independent career, Canada still remains as a great and flourishing self-governing dominion.

Australia was discovered in the beginning of the 17th century. The first Australasian settlements of Great Britain were penal colonies. New South Wales, discovered in 1770, was established as a penal colony in 1788; Tasmania (Van Diemen's Land), discovered by Tasman in 1642, followed in 1803. West Australia, for some time a penal settlement, was founded as a free colony in 1829; Victoria (Port Phillip) was colonized in 1835, and made an independent colony in 1851; South Australia was settled in 1836; Queensland became a separate colony in 1859; New Zealand, discovered by Tasman in 1642, began to be used in connection with the whale fishery about 1790, was settled in 1839 and made a colony in 1840. In 1851 gold was discovered to be plentiful in Victoria. This gave a great impetus to the prosperity of the Australian colonies, and the influx of population it caused has largely contributed to promote their general development. A federal union of the British colonies in Australia was proclaimed 1 Jan. 1901, with the title of the Commonwealth of Australia. The Fiji Islands became a colony in 1874, and other islands in the Pacific have been acquired since, as well as part of New Guinea and part of Borneo.

The acquisition of the South African colonies dates from the Napoleonic period, the Cape Colony and Mauritius being both secured to Great Britain in 1814. Natal was proclaimed a British colony in 1843. The Guinea Coast settlements date from the 17th century. Extensive spheres of influence have been recently acquired, being partly developed by chartered companies.

In Europe Great Britain has only two possessions of the nature of colonies, acquired for military reasons: Gibraltar in 1704; Malta and Gozo, 1800.

It is estimated that the existing British colonies and dependencies embrace fully one-fifth of the land surface of the globe, and a rather larger proportion of its population. The whole of the British colonial possessions have been grouped in about 40 administrative divisions and they are situated in every quarter of the globe. See GREAT BRITAIN.

According to their governmental relations with the Crown the colonies are arranged under three heads: (1) Crown colonies, in which the Crown has the entire control of legislation, while the administration is carried on by public officers under the control of the home government; (2) colonies possessing representative institutions, but not responsible government, in which the Crown has no more than a veto on legislation, but the home government retains the control of public officers; (3) colonies possessing representative institutions and responsible government, in which the Crown has only a veto on legislation, and the home government has no control over any officer except the governor. With the exception of the self-governing Dominions, all colonies are disabled from such acts of independent sovereignty as the initiative in war, alliances and diplomacy generally.

France.—France was somewhat late in entering fully upon a colonial career, being retarded by internal dissensions and religious wars. Between 1627 and 1636 Pierre Belain d'Esnambuc colonized Saint Christopher's, Guadeloupe and Martinique. Champlain was the pioneer of the French in the exploration of the North American continent, where they soon had considerable possessions, including Canada — in which they had settlements as early as 1604–05, and where Champlain founded Quebec in 1608 — and Louisiana, colonized in 1699. Commercial companies were then deemed essential in colonizing, and a West India Company and an East India Company were established by Colbert in 1664. He purchased on several West India Islands, as Martinique, Guadeloupe, Saint Lucia, Grenada and others, settlements already formed by private persons, and sent out colonists in 1664 to Cayenne. But the settlements in part of San Domingo, by the buccaneers, became of more importance than those effected by the government. The West India Company survived only 10 years. The East India Company, after fruitless attempts to form a colony in Madagascar, founded Pondicherry on the Coromandel coast in 1683. This became the capital of extensive French possessions in the East Indies. The French also acquired Bourbon (Réunion) in 1649 and the Isle de France (Mauritius) in 1715. At the beginning of the 18th century France had attained an important position as a colonial power. In North America her settlements extended from Canada to California, particularly along the Great Lakes and the Mississippi River, embracing many districts which have since become of the highest importance. Nova Scotia (Acadie) and Newfoundland (Terre Neuve), which had been disputed with Great Britain, were then in her possession. Her West Indian islands were more flourishing than those of England, and she still had a prosperous career before her in India. The superiority of the fleet of England gave that power a great advantage in colonial contests, and many of the French colonies subsequently fell under the power of Great Britain. The struggle for the supremacy in India, though France was finally unsuccessful, was

long and gallantly maintained, and more than once seemed to promise a different issue. The North American colonies were partly lost by conquest and partly suffered to fall into decay. Of the West India possessions several were taken by Great Britain and finally ceded to her. Canada was finally ceded to England in 1763; Louisiana, after being surrendered to Spain, to prevent it from falling into the hands of the English, was sold by Napoleon to the United States in 1803. At the general pacification of 1815 France recovered some remains of her colonial possessions, and since then she has acquired extensive regions beyond sea, some of them highly valuable. She occupied in 1830 and began in 1833 to colonize Algeria, a country whose irregular and lawless government had exposed her as well as other European states to frequent annoyance. Tunis, Senegambia, great tracts of the Sahara, Sudan and Kongo regions, the islands of Madagascar and Réunion are all comprised in France's African possessions, while in Asia she possesses a large portion of the Indo-Chinese Peninsula, and in America French Guiana. Some of the French colonies are represented in the National Assembly by members chosen for the purpose. See FRANCE — COLONIES.

Denmark; United States; Sweden.— Denmark established an East India Company in 1618 with a view to enter on the colonial trade; and other companies were afterward formed. In the same year, with the formation of the first company, the colony of Tranquebar was founded on the Coromandel coast. Its success was fluctuating, like that of the companies formed to manage it, and at last, in 1845, it was sold to the East India Company. Saint Thomas in the West Indies was settled by the Danes in 1672; Saint John and some of the smaller islands in the same group (the Virgin Islands) were also occupied by them. The island of Santa Cruz was purchased from France in 1733. By a treaty signed 4 Aug. 1916, the West India islands belonging to Denmark passed into possession of the United States at the purchase price of $25,000,000. Formal transfer took place on 31 March 1917, and the islands are now called the Virgin Islands of the United States. Sweden established an East India Company in 1741. She acquired the island of Saint Bartholomew from France in 1785, but restored it in 1878, and has now no colonies.

Germany.— A German historian of the colonial movement dates his story from the end of the Crusades, while another, not to be outdone in the national virtue of thoroughness, seeks its origins in pre-Christian annals. For practical purposes, the German colonial movement, as we know it to-day, is barely over 60 years old. There were genuine if tentative efforts at colonization as early as the 17th century, when the Great Elector of Brandenburg established settlements on the west coast of Africa. Earlier still the Hanseatic Towns would have traded with foreign territories had they not been frowned upon at home. Prussia's and Germany's dreams of world-conquest and colonization were dispelled when Frederick William I of Prussia (1713–40), more concerned to assure his sovereignty at home, abandoned the Great Elector's settlements. The new policy was shared by Frederick the Great (1740–86), who considered all distant possessions «a burden to the state» and «a village on the frontier worth a principality 250 miles away.» Nearly a century and a half was to pass before the colonial question again seriously entered German politics. Germans are in the habit of dating the modern movement from 1874, when Great Britain annexed the Fiji Islands, in which German trade had long flourished. This incident, however, did not create a colonial spirit, but about this time the explorer, Gustav Nachtigal (1834–85), visited various parts of Africa, carrying presents to native chiefs from the German Emperor, though he made no attempt to acquire territory. At this time while great portions of Africa were being brought into the British sphere of influence there was no appreciation of colonial aims in Germany, and all the nation's effort was directed toward developing at home the advantages which had followed from the successful war with France. It was only in 1883 that the first colonial society, the Kolonial Verein, came upon the scene. Up to then there was no systematic colonial enterprise and no organized colonial policy in Germany. It was the Bremen trader, Herr Lüderitz, who gave to Germany her earliest colonial possession. In 1882, by treaties with native chiefs, he acquired land in the Bay of Angra Pequena, on the southwest coast of Africa, and he pressed the home government to support his claim. For a time nothing was done, until the claims of Herr Lüderitz were disputed by agents of the British Crown. Lüderitz's appeal for protection roused Bismarck's interest and he formally annexed Lüderitzland. This gave Germany the coastland extending from the Orange River to Cape Frio, exclusive of Walfish Bay. What happened in Southwest Africa happened, too, in the Northwest. German claims to territory on the Cameroon River led likewise to disputes, and here also Bismarck cut the Gordian knot instead of waiting for it to be unravelled. In the Pacific German settlements had been established since 1880 for trading purposes on the north coast of New Guinea, and over these, as well as the New Britain Islands, the German flag was hoisted in the winter of 1884. These two new acquisitions were promptly renamed, the one being called Kaiser Wilhelm's Land and the other Bismarck Archipelago. The following year saw fresh annexations in East Africa, to develop which a wealthy company was formed, and in the Pacific the Marshall Islands and part of the Solomon group were also acquired. The treaties under which Germany declared a protectorate over the East African regions were concluded by Dr. Karl Peters, an ardent colonial pioneer, who entirely subordinated means to ends. Each of these annexations served as a starting point for large extensions of territory, so that after two years of diligent search and salvage amongst the still unregarded regions of the African continent and the Pacific, Germany found itself in possession of a colonial empire having an area of 377,000 square miles and an estimated population of 1,750,000. Bismarck never had great faith in colonies, his policy being consolidation at home, and he only gave his consent to the expansionist policy when he knew the country to be behind him. Caprivi, Bismarck's successor, was hostile to the colonial movement

and it was not until he fell that the traditions of colonial expansion were revived under Prince Hohenlohe in the nineties. Thus the Caroline Islands were annexed in 1899, also the Pelew and Marianne groups. In the same year the Samoan Islands were brought under the German flag; already in 1897 Kiau Chau had been wrested from China. The total area of Germany's colonial possessions in 1914 was 1,027,820 square miles, with a white population of 24,389 and a native population of 12,041,603. In the course of the European War one after another of her colonies became lost to Germany. Togo was taken by combined British and French forces on 7 Aug. 1914. Cameroon was conquered by French and English troops on 18 Feb. 1916. South West Africa fell to the South African forces of General Botha on 9 July 1915 and is administered by the Government of the Union of South Africa. East Africa was occupied during the war by British, Belgian and Portuguese forces and was finally conquered in 1917. Kiau Chau fell to combined Japanese and British forces on 7 Nov. 1914. In the north Pacific the German possessions were captured by the Japanese shortly after the outbreak of the war in 1914 and were handed over to the Australian forces. The islands south of the equator are administered by Australia, those north of the equator by Japan, and Samoa by New Zealand. German colonial administration has not been happy in its methods nor yet in its officials. The principle laid down by Bismarck was soon departed from: the trader, having obtained protection, went back to his plantation, his compound, his stores; he certainly was not urged to play any part in the government of his colony; gradually the whole system of Prussian bureaucracy was introduced in each of the colonies, large and small. The secret of the administrative order that reigns at home is «system,» and it was taken for granted that if sufficient «system» were introduced into the government of the colonies the same results would follow. Furthermore, far too little regard was paid to native customs and traditions of life. Instead of studying native law systematically and regulating administration in each colony according to its peculiar traditions, all colonies alike were governed according to set Prussian legal maxims interpreted in a bureaucratic spirit by jurists with little experience of human nature, and none at all of native usages. The choice of officials was also unfortunate in a majority of cases; the colonies being regarded as relief institutions for the benefit of men who had failed at home. It was declared from the throne in 1888 that it must be a solemn duty of the Empire to «win the Dark Continent for Christian civilization.» Not much Christian civilization, or civilization of any kind, was carried to the colonies. Stories of slavery, violence, cruelty, illegality and lust, committed both by officials and planters, were reported only too frequently by missionaries and clean-handed men in the colonial service, who could not see these things and be silent. The use of force as the only method of civilizing the native was constantly advocated with a daring frankness. In South West Africa the Hereros were decimated by the armed forces of Germany. General von Trotha wrote in his proclamation of 2 Oct. 1904: «The Herero people must leave the land. If it refuses I shall compel it with the gun. Within the German frontier, every Herero, with or without weapon, with or without cattle, will be shot. I shall take charge of no more women and children, but shall drive them back to their people or let them be shot at.» The leader of the German People's party in the Reichstag said before that body on 24 March 1906 that «The legal position of the blacks is miserable in the extreme. The honor of the German name suffers under this absolutely arbitrary system. We have lost the sympathy of the black race.» The Great War brought about the loss to Germany of its colonial possessions acquired within the memory of the majority of men living. On the colonial record of Germany as on many other records of that nation must be written in large letters the word failure.

Italy.—Italy has also shown the same ambition, and has established the colonies of Eritrea and Italian Somaliland in East Africa; acquired the colony of Libya on the North coast of Africa, and in 1936 conquered Ethiopia by a war which began in October, 1935.

The colonial policy of paternalistic countries as Spain, Portugal and France naturally differed from that of commercial and industrial nations like England and Holland. In the former the expense and risk of colonizing was borne by the government, who retained direct control over the colonies and their productions; but in the latter the work, being too much for individual enterprise, was entrusted to companies, whose charters conferred on them not only exclusive privileges in regard to trading, but also extensive powers of conquest and administration. In respect to trade a very exclusive and jealous policy long prevailed, but since the adoption of a free-trade policy in Great Britain the whole trade of her colonies has been thrown open without reserve, as far as the privileges of the mother country are concerned, to the competition of foreign nations. Other countries, while not following her commercial policy entirely, have relaxed more or less the stringency of the regulations affecting their colonial trade. See AMERICA, COLONIZATION AND DISCOVERY; CANADA — ERA OF EARLY DISCOVERIES; COLONIES AND COLONIZATION; IMPERIALISM.

COLOPHON (Gr. *Kolophon,* "summit"), an ancient Ionian (Greek) city of Asia Minor situated at a short distance from the coast and about 15 miles north of Ephesus. Its inhabitants were removed by Lysimachus after the death of Alexander the Great. Colophon was one of the places that claimed to be the birthplace of Homer. It was the native city of Mimnermus and other poets. Its site was discovered in 1887 by the German explorers, Schuchhardt and Wolters. Proverbially Colophon came to mean "a finishing stroke" because of the many instances in which the city's cavalry carried the day. The word took this proverbial meaning in Latin and was used by early printers as the imprint at the close of a volume; commonly used before the introduction of the title page. See next article.

COLOPHON, kŏl'ō-fŏn, an inscription at the "Finis" of a book, giving the printer's name and date and place of printing; in the early days of printing nearly all books had colophons. Usually they are ludicrous in the extravagant claims the printers made for the unapproachable excellence of their handiwork; but some are modest and dignified, while a few are pathetic, showing the hard struggle made by masters of the noble craft for a bare subsistence.

COLOPHONIUM. See Rosin.

COLOPHONY, a name formerly used for common rosin (q.v.), but now seldom so used, though still given in the dictionaries.

COLOQUINTIDA. See Colocynth.

COLOR. Color may be studied objectively as a wave phenomenon (see Light), in its psycho-physiological aspect as a retinal stimulus (see Vision), or, subjectively, as an appearance or ocular sensation; this last is the viewpoint of the present article.

Isaac Newton ('Philosophical Transactions,' No. 80, 1672) was the first to show that white light (sunlight or daylight) may be resolved into elemental colored lights or rays which cannot be further decomposed, but which on being superposed form white light. The question whether sunlight contains these colors in the form of a mixture analogous to a mixture of, say, nitrogen and oxygen gases in the air or is a compound, as water is of hydrogen and oxygen, belongs to physics. Newton adopted the first point of view; at the present time the second is gaining favor. The elemental lights, distinguished visually by their colors, are seen in the rainbow, the sparkle of a diamond, in soapbubbles, in a film of oil on water, by looking at one's eyelashes through nearly closed lids, and in many other phenomena discussed in physical optics under the names dispersion, interference, absorption, polarization, fluorescence, diffraction, refraction. They are called spectrum colors — popularly, "colors of the rainbow" — and are monochromatic, i.e., they consist of single colors (colored lights or rays) that are elemental in the sense in which this term is used in chemistry. We are accustomed to think of the spectrum as having only six colors: red (R), orange (O), yellow (Y), green (G), blue (B), violet (V); Newton named a seventh, indigo, situated between B and V. But the number of colors is enormously great; Aubert ('Physiologie der Netzhaut,' 1865) estimated the solar spectrum to contain about a thousand distinguishable hues, of which, according to Rood ('Modern Chromatics,' 1881) 2,000,000 tints and shades can be distinguished. However, these differences cannot be seen *in situ* in the spectrum because the color areas are too small. Luckiesh ('Color and its Applications,' 1915) states that 55 distinctly different hues have been seen in a single spectrum.

Color Sensation.— Color is a sensation produced through the excitation of the retina by rays of light. Thus black (Bk) and white (W) are color sensations, although Bk is due to no, and W to complete, stimulus. The infra-red rays — below the red end of the spectrum — and the ultra-violet — beyond the violet end — are invisible. Heat is the principal effect of the infra-red and chemical action, as on a photographic plate, that of the ultra-violet rays. To the physicist all of these visible and invisible emanations are regarded as electromagnetic waves differing essentially in wave length alone. All have chemical and thermal effects but only some give to the eye the sensation called color. Although none of the spectral colors can be resolved into others, some can be imitated to the eye by combinations of others. Combinations of R and V produce purples which are not in the spectrum at all; such compounds are nevertheless resolvable into their constituents by spectroscopy. Two colors not distinguishable to the eye may have quite different compositions. For example, a solution of potassium dichromate and one of potassium dichromate and neodymium ammonium nitrate in suitable proportions impress the eye as having precisely the same yellow color; but whereas a mercury arc light will look yellow on being viewed through the first solution, it will look brilliant green through the second. No pigment is monochromatic, yet it is possible in many cases to match spectral colors by means of pigments. Color to the eye is therefore not color in the sense of being one definite constituent of white light. Since color is entirely subjective it must be influenced by personal idiosyncracy; indeed some people are color-blind and cannot, for instance, tell red from green. (See Vision). On the other hand, santonin poisoning produces, in otherwise normal people, a pathological condition called chromatopsia, in which all "colors" are yellow. In short, the eye is unable to analyze color in the way that the ear can detect the component tones in a chord.

Color Constants.— Artists speak of cold, warm, advancing, and retiring colors. By warm are meant red, orange and yellow, and any tendency toward them; it has no connection with heat, but is suggested rather by the luminous glow of sunlight. An advancing color

seems to be nearer the eye than one which is called retiring; the effect is evident in only a few simple cases: orange seems to be nearer than green when both occur in juxtaposition on the same surface, green nearer than violet, yellow than red, red than blue, black than yellow. The reader may easily experiment with the excellent colored coated-papers suitable for the purpose, various sizes of which can be obtained in black, white and in 18 spectral hues, with two tints and two shades of each. Color has three characteristics: hue, purity or saturation, and luminosity or brightness. Hue is color *per se*, such as blue, pink, black, etc.; purity depends on freedom from admixture with white; only monochromatic colors are saturated. Luminosity depends on the amount of light given by the color. A tint is a departure from a normal or dominant spectral hue in regard to purity, i.e., tints are whiter than the arbitrarily selected normal. A shade is darker than the normal and may be produced by decreased illumination or by the addition of black. It must be clearly understood that luminosity does not affect purity: a tint cannot be made to look as saturated as its normal merely by decreasing the illumination, thus pink never looks red in a subdued light. A compound color can be defined accurately only in terms of the characteristics of its monochromatic components. But every color, simple or compound, except purple, can be matched so far as the eye is concerned by a tint or a shade of some simple spectrum hue.

Color constants are measured with a spectrophotometer, which is a combination of a spectroscope with a photometer. The spectroscope produces an ordinary white-light spectrum, one narrow transverse band of which can be passed through the photometer; at the same time white light of any intensity is superposed on this colored band. The colored light which is to be examined — in the case of a colored surface the light reflected by it — also passes through the photometer and forms a field next to the combination of spectral ray and white light. By selecting the proper hued spectrum ray, controlling the added white and adjusting the resultant until it matches in color and brightness the light to be examined, we can determine hue, saturation and luminosity. Descriptions of instruments and full references are given by Luckiesh. The following are typical results; they will vary with the reflection coefficient of the surface, i.e., with the relative amount of white light it reflects. The wave lengths of the hues are expressed in microns: 1 micron = 0.001 millimeter. The columns headed «per cent white» give the amount of white light which had to be added to the normal spectrum hue to reduce its saturation.

(ABNEY, 'RESEARCHES IN COLOR VISION,' 1913)

Pigment	Hue	Per cent white
Vermilion	0.610 μ	2.5
Emerald green	.522	59
Fr. ultramarine blue	.472	61
Brown paper	.594	50
Orange	.591	4
Chrome yellow	.583	26
Blue-green	.500	42
Eosin dye	.640	72
Cobalt blue	.482	55

(NUTTING, 'BULLETIN BUREAU STANDARDS,' 1913, 9, NO. 187)

Materials	Hue	Per cent white
Sulphur	0.571 μ	48
Cork	.586	56
Tobacco leaf	.597	65
Chocolate	.595	70
Butter, dark	.580	28
Paris green	.511	56
Manila paper	.582	65
Copper	.597	70
Brass, light	.575	60
Gold, medium	.591	64

(L. A. JONES, 'TRANS. I. E. S.,' 1914, 9, P. 687)

Source	Hue	Per cent white
Sunlight	.....	100
Average clear sky	0.472 μ	60
Tungsten lamp	.588	35
Carbon lamp	.591	25
Nitrogen tungsten lamp	.584	45
Mercury vapor arc	.490	70
Carbon arc	.584	62
Acetylene flame	.585	36

These results are color matches rather than color analyses. They show, for example, that highly colored butter, manila paper, chrome yellow paint, the nitrogen tungsten lamp and the carbon arc light are all of about the same hue and differ only in purity and brightness, i.e., they are tints and shades of one another. As the three observers did not use identical light sources in their experiments, the purities in the tables are relative. The following values from Hurst ('Color,' p. 17) give a rough idea of the luminosity of, or the amount of white light reflected by, various pigments in terms of white paper as a standard.

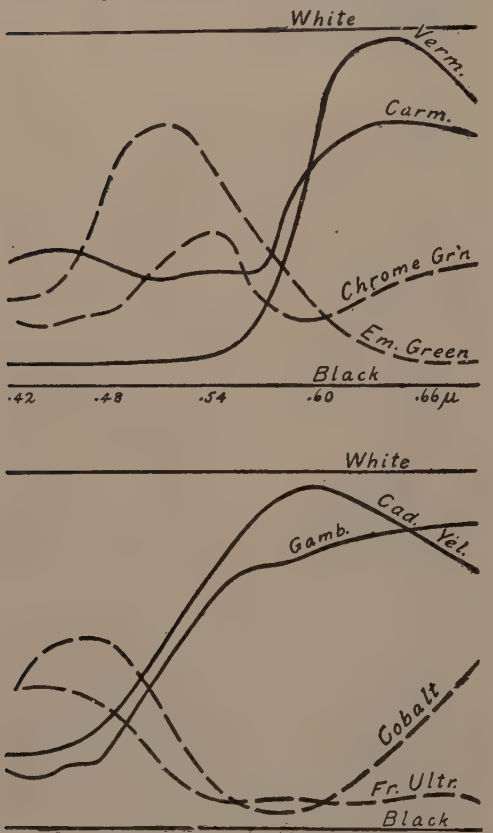
White paper	100	Emerald green	51
Vermilion	20	Ultramarine	50
Orange red	40	Umber	22
Yellow ochre	56	Chrome yellow	61

On comparison with the first table it is seen that although vermilion is very pure, very nearly saturated, it reflects comparatively little light. The two sets of numbers are quite independent and express two different characteristics of color.

Color Analysis.— Analysis of a compound color is used here to mean separation into spectral components. For example, French ultramarine is a fair match to what is regarded as the typical spectral blue of wave length 0.472 microns; both give rise to the same sensation and are therefore physiologically identical, yet the spectrum ray is monochromatic and the pigment decidedly complex. If the light reflected from a colored surface is analyzed spectroscopically it is found to contain all the spectrum hues in varying intensity.

The following diagrams, adopted from Luckiesh, give spectroscopic analyses of certain pigments. Vertical distances indicate the relative intensities with which the wave lengths along the base are reflected and correspond to luminosities in the absorption spectra. The area under a curve measures the luminosity of the pigment itself. White is a horizontal line at greatest height because it reflects all colors equally; black reflects none and therefore is chosen as the base. Gray would be some intermediate horizontal line. No analyses of mixed pigments are as yet available and it is difficult to predict the exact form of the resultant curve. However, we can arrive at approximate results. According to the diagrams a surface painted

with cadmium yellow will look intensely yellow when illuminated with monochromatic yellow light, orange in orange light, red in red and green in green, but in blue or violet light it will be grayish. French ultramarine will be violet, blue, green in corresponding illuminations but grayish in yellow, orange, red. The only color which cadmium yellow and ultramarine both reflect is green, the others being largely but not entirely absorbed. The green produced by a mixture of these two pigments although far from being monochromatic is much more nearly so than the pigments themselves. But its luminosity has been considerably reduced by absorption; in fact a mixture of monochromatic blue and yellow pigments would be black be-



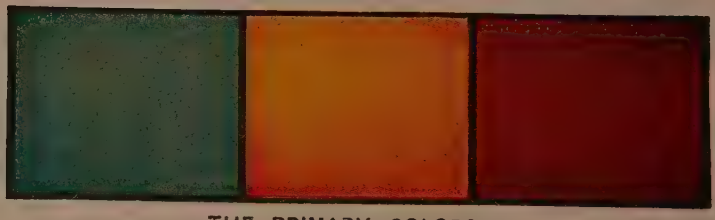
Spectrum Analyses of Pigments

cause no light would be reflected at all. Mixed pigments tend toward blackness; painters therefore select pigments which possess inherent color and do not mix unless a subdued, murky or grayed effect is desired. Unfortunately there is as yet no accepted theory of inherent color; it is not known why chromium oxide is green, hydrated ferric oxide red or ferric hydroxide yellow. Consult 'Berichte d. deut. chem. Gesell' (1906, 39 p. 1959), and *Journal of the Chemical Society* (1906, 89 p. 1787); see also DYEING.

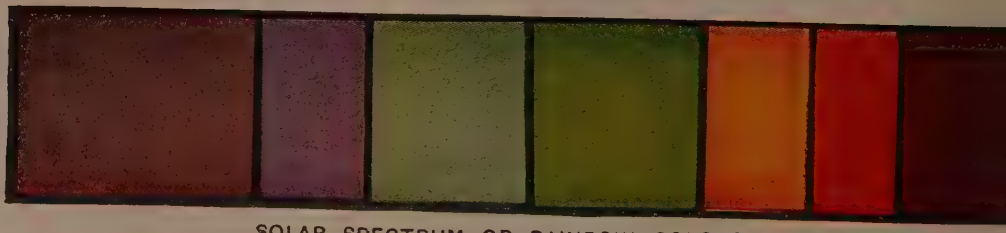
When a surface is illuminated with colored light, as in stage lighting effects, the hue actually seen depends on the local color of the surface, on the light reflected before absorption takes place and on the remainder reflected after absorption. Ogden Rood found that non-monochromatic yellow light looked bright green on Prussian blue and white on ultramarine. The Prussian blue had evidently absorbed all but the green component that must evidently have been in the yellow, while, as will be seen later, the ultramarine had absorbed all but the monochromatic yellow component. In the first case green was the dominant hue reflected, in the second case it was yellow plus blue. This shows that the parts played by absorption and reflection are difficult to predict.

Additive Combinations.— Combinations of colors are always combinations of spectral lights whether they are made additively by direct superposition of the components or subtractively by absorption as in a mixture of powders or solutions. When red and green spectrum rays are thrown upon a white surface both colors are simultaneously reflected to the eye and give the sensation of yellow; on the other hand a mixture of red and green paints will in certain proportions give a gray which may be reddish or greenish, but never yellow, because together they subtract from the white light (daylight, etc.) which illuminates them all colors except those whose combination impresses the eye as gray. Such apparently contradictory results have been the source of many absurd controversial "theories of color." There are facts about color and theories of the psychophysiological processes of color perception but no theories of color other than chemical theories of molecular grouping.

Colors may be added in several interesting ways. Fine lines alternately red and green or blue and yellow, etc., ruled close together on white paper and examined from a distance through the large end of opera glasses so that the individual lines are not distinguishable give the eye two simultaneous sensations whose effect is quite different from that of the corresponding pigment mixtures. This method was used by Miles as early as 1839. It may be performed also by painting one end of a pack of papers with one color and the opposite end with another and then reversing alternate papers; or otherwise by stippling points of different hues on a white surface, or by using the color-wheel described later. Artists often employ the stippling process with beautiful results because the surface so treated fluctuates in hue according as one or another of the components momentarily predominates by reason of the varying degrees of fatigue of the color nerves in the retina. It has been found experimentally that all hues can be produced by suitable combinations of three physiological primaries: monochromatic red, green, blue (or violet). Thus red plus green in different proportions produce additively all the hues from red through orange, orange — yellow, — yellow, yellow — green, green; red plus blue give violet, red — violet, blue — violet and the purples; blue plus green produce blue — green and green — blue; red plus green plus blue in certain proportions give white, in others they reproduce colors obtained from pairs of the primaries. This is the first great group of phenomena that can be accounted for only by studying the subjective effect of color. It is strikingly illustrated by the Lumière, Joly and Ives-Cros processes of color photography (see



THE PRIMARY COLORS



SOLAR SPECTRUM OR RAINBOW COLORS

Diagram illustrating the primary, Solar spectrum or rainbow colors and law of the complementary colors.

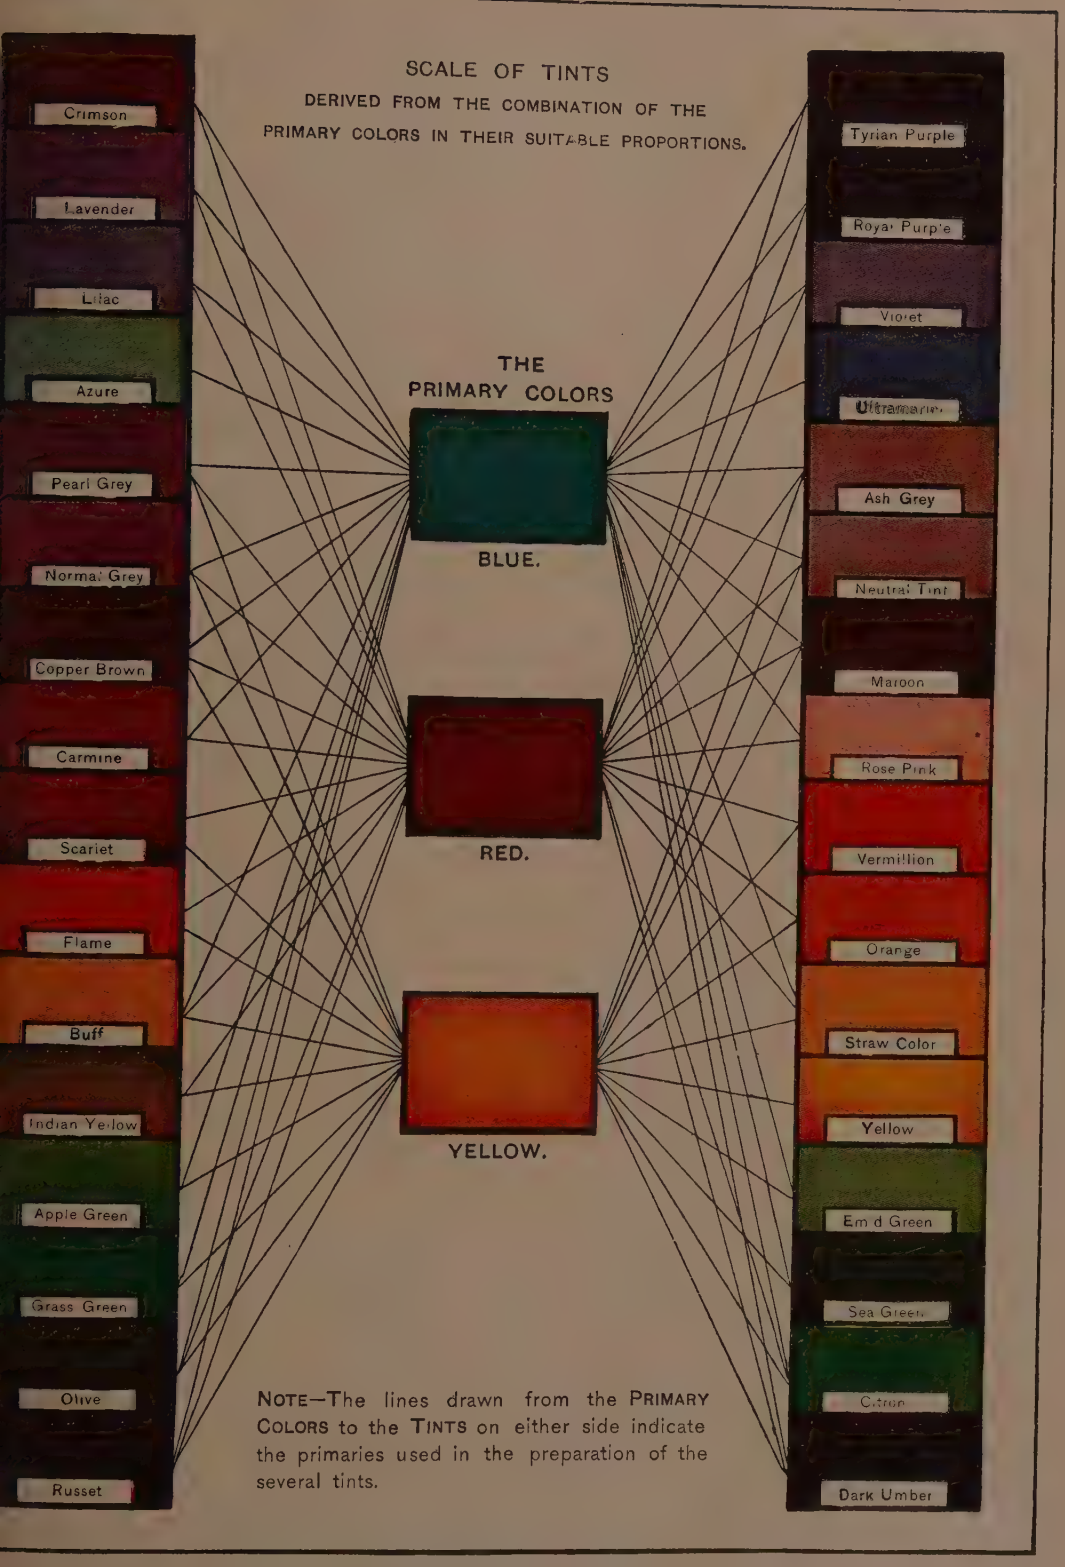


Diagram illustrating the primary colors and their combinations or tints.

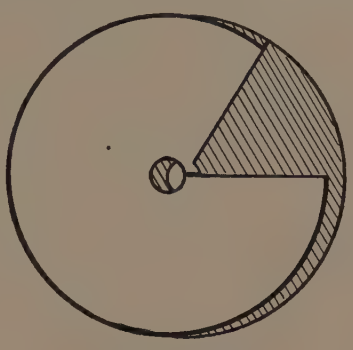
COLOR PHOTOGRAPHY), in all of which three photographs taken through red, green and blue filters are dyed with these respective colors and then presented simultaneously to the eye. Ives and Cros used three separate filter screens, Joly ruled a single one with lines alternately red, blue, green, and Lumière formed the screen directly on the sensitized plate by spreading it with a thin paste containing potato starch grains, some of which were stained red, some green and some blue.

The reasons for the facts in the above group are unknown. But by assuming a certain functioning of the retina we can form a theory which will correlate them. Like every theory this is outside of the region of fact and non-fact and is simply a mechanistic formula by means of which a whole class of phenomena can be stated in terms of a selected few. The Young-Helmholtz method of explaining color vision (see VISION) hypothecates the existence of three sets of nerves in the retina: one is strongly stimulated by the red–orange end of the spectrum and less by the rest, another most strongly by the yellow–green region and less by the ends and the third by the violet–blue end and rapidly less as we approach the red end. It is then assumed that when all three sets of nerves are acted on in about the same degree the sensation of white is produced because it is a fact that red plus green plus blue does produce white. Consider now the superposition of yellow and blue lights; according to the theory yellow stimulates red and green because red plus green equals yellow. Therefore yellow plus blue equals red plus green plus blue equals white. This does not tell why yellow and blue cause white but it enables us to predict it without experiment. If however it can be shown directly or indirectly that the eye really does contain such nerves the Young-Helmholtz theory at once enters the realm of fact. It may be interesting to note that the whitening of linen and cotton fabrics by bluing in the laundry consists in adding hardly perceptible traces of indigo or Prussian blue to the ivory yellow tint to which they revert after being washed; it is essentially not a bleaching process.

Maxwell's color wheel affords a simple and interesting method of experimenting with additive combinations. It owes its present form and use to J. C. Maxwell although it was known to the astronomer Ptolemy in the 2d century and was rediscovered by the Dutch physicist Musshenbroek in the 18th. A smooth, stiff pasteboard disc graduated at its circumference into 25, 50 or 100 parts is mounted on the shaft of a small electric motor which can be operated by a single dry-cell. A circular piece of paper painted, for instance, half vermilion and half emerald green is placed over the shaft against the disc and a small wooden sleeve is then forced on so that paper and disc may turn with the axle when the motor runs. When the painted disc turns red and green are presented alternately to the eye and if the alternation is so rapid that one color occupies the place of the other before the retinal impression of the latter has vanished then both stimuli act at the same time. The resultant color will be yellowish: not pure yellow, because the pigments are not monochromatic. Maxwell introduced single-colored discs, each one perforated at the centre and slit along a radius; two or more such discs can be slipped over one another and adjusted to expose to view sectors of any desired angle. They may be cut out of the Bradley colored coated-papers;



Maxwell Color Discs

a complete set will consist of the following colors: red, orange, yellow, green, blue, violet, black, white and neutral gray and should be made in two sizes, one about twice the diameter of the other. Dividers, into one leg of which a needle sharpened to a chisel edge is set, form a convenient instrument for cutting circles. If the motor is small the discs should not be much more than two inches in diameter, otherwise air resistance will retard the rotation enough to produce flicker. This resistance varies as the fourth or fifth power of the diameter depending upon whether the speed is low or high, and is therefore 16 to 32 times as much for a four-inch disc as for one half the size. The discs must be put together so that the radial edges do not catch the wind.

Very instructive experiments may be made by putting together a colored disc with a black, a white or a gray one. The brightness or luminosity of a color may be diminished by rotating black with it; this produces a shade such as would be seen in lessened illumination but does not reduce the hue or the saturation. The saturation may be lowered by using a white disc; the resulting colors are tints. But if a neutral gray and a colored disc of equal luminosities are rotated simultaneously the saturation will be lowered without change of hue or brightness. In short, black absorbs all colors and therefore changes only the amount of light reflected from the composite disc; white reflects all and, in effect, adds the physiological primaries to the disc; gray may be regarded as a mixture of black and white (or also, as will be seen presently, of other pairs) and is thus more luminous than black and more saturated than white. Ogden Rood succeeded in matching almost 500 colors with combinations formed of seven discs painted with the following water-color pigments, the numbers in parentheses being the wave lengths, in microns, of the corresponding spectral hues: matt white (zinc oxide), matt black (lampblack), vermilion (0.644), mineral orange (0.614), light chrome yellow (0.585), emerald green (0.521), artificial ultramarine (0.425). His formulas are given in the 'Standard Dictionary' under *spectrum*. The wave lengths of the Bradley papers are: red, 0.657; orange, 0.608; yellow, 0.579; green,

0.516; blue, 0.469; violet, 0.421. Consult also Bradley, Milton, 'Elementary Color' (1895).

Some pairs of discs produce gray which must be regarded as a shade of white, or so to say, as a dark white, due to the comparatively low luminosity of the pigments; the corresponding spectral hues, being monochromatic and of greater brightness, produce real white. Two colors whose addition produces white are called physiological complementaries; their number is unlimited. Physiological complements depend of course upon the source of illumination, for if the subdued white which they produce in daylight be examined in some other illuminant it will partake of its color. Additive combinations in general tend toward white; if actual lights are superposed the luminosity of the resultant equals the sum of the luminosities of the components, but on the color wheel the resultant has a luminosity equal to the average (weighted mean) brightness of the sectors. When the eye is stimulated to fatigue by any hue, say red, its complement is subjectively called up because the eye then sees all the constituents of white except red. Now since red and green make white, and all the spectral hues together also make white, white minus red equals green; that is, green is complementary to red.

ADDITIVE COMPLEMENTARY HUES

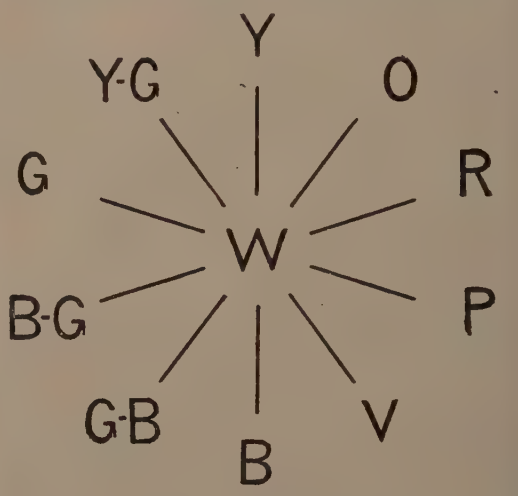
Wave lengths, μ		Colors *	
0.6562	0.4921	Yellow,	Genuine ultramarine.
.6077	.4897	Green-yellow,	Artificial ultramarine
.5853	.4854	Gamboge,	Cobalt blue.
.5739	.4821	Red,	Green-blue.
.5671	.4645	Orange,	Cyan blue.
.5644	.4618	Green,	Purple.
.5636	.4330		

* The names do not correspond to the wave lengths at the left.

Subtractive Combinations.— When two pigments are mixed each subtracts from white light those elements it cannot reflect. The resultant hue is therefore never identical with the corresponding additive mixture and is usually entirely different. It was known to antiquity that any color may be fairly matched in hue although not in purity by proper mixtures of yellow, blue, red. These are the pigment primaries; to them white and black must be added to lighten or darken the hues to be produced. The production of all colors by combinations of the subtractive primaries is beautifully illustrated in the three-color process of printing in ink reasonably faithfully copies of paintings. This work has now attained the dignity of an art *per se*. A mixture of yellow, blue and red in about equal intensities gives the effect of black because they absorb practically all the constituents of white light. If this black is spread thinly as a tint it becomes gray. In general, mixtures of pigments tend toward blackness on account of the absorption of color and thus of light.

Pigment primaries have complementaries; thus red and green, purple and yellow, blue and orange are complements and produce black or gray according to the density of the mixture. This gray is to be regarded as a tint of black, that of additive complements as a shade of white; the difference between the grays is of the utmost importance and is by no means a verbal quibble. A small amount of a color added to its complement dulls or grays the latter; such grayed hues are among our most beautiful colors and are used with wonderful effect, for instance in textile fabrics and pottery. Unusually handsome charts illustrating pigment mixtures have been prepared by commercial firms of Boston and New York.

Contrast and Harmony.— The effect which two colors have in modifying each other's hue when they are placed in juxtaposition has been determined with reasonable certainty. It can be studied by putting colored strips of paper next to each other or by placing a small piece on a larger one. The general result of such experiments is that each color becomes tinged with the complement of the other, or rather is moved



Rood's Color Circle

nearer the complement. The diagram above was invented by Rood for predicting these changes. Diametrically opposite colors are physiologically complementary. If yellow and red are placed side by side the hue of each shifts around the circle toward the complement of the other, i.e., yellow becomes greenish, red becomes more violet or less red. In the case of red and blue, the red becomes tinged with orange and the blue looks greenish. Complements intensify each other. Whether or not these effects are agreeable depends on idiosyncracy and circumstance. Red makes yellow look greenish; this may be pleasant or not — or neither — in, say, a wallpaper design. But a sallow-complexioned woman does not wear a red dress unless she wants to look bilious; green clothing would make her look ruddier unless some of the green were reflected to her face, in which case red would have been better. The question is not quite as simple as Rood's circle, for the influence of the complement is not evident when two equal areas are separated by any third color; furthermore, a small area has no noticeable effect on a much larger one. Chevreul, Rood, Church, Bruecke and others have found from examinations of paintings, ornaments, etc., of generally accepted beauty that the following pairs and triads are considered to be harmonious and pleasing.

Good pairs: red, blue; red, blue — green; orange, green — blue; yellow, violet; yellow, black.

Good triads: red, yellow, blue; red, yellow, green — blue; orange, green, violet; white, yellow, violet.

The following are to be regarded as bad:

Bad pairs: green, blue; yellow, green; violet, red; violet, blue; crimson, orange; orange, yellow.

It will be seen on comparing these combinations with the diagram that colors which do not go well together, e.g., green and blue, are adjacent in the circle while good pairs and triads, e.g., red, yellow, green, are separated. Tints, shades and grays, being less colorful or vivid, form less offensive combinations and are easier to harmonize. By generalizing the foregoing results we arrive at some of the various methods of harmonizing colors; they show rather how to avoid discord than to produce beauty.

Harmony by Contrast: use of complements in pure hues, tints, shades or grays. An example of this is the use of red (figure, chimney, etc.), in a green landscape.

Monochromatic Harmony: tints, shades and grays of a single hue as in the different greens of a landscape. This includes harmony by variation or gradation. Ruskin in 'Elements of Drawing,' says "The victorious beauty of the rose as compared with other flowers depends wholly upon the delicacy and quality of its color-graduations."

Harmony of Analogous Colors: tints, shades or grays of components which are side by side or close together in the color circle, for instance in autumn leaves which contain various tones of yellow, orange, red, brown and intermediate colors. The effect is usually not pleasing when the normal hues are employed yet the beauty of green trees, blue sky and blue-green water furnishes a striking exception to the rule.

Chevreul, director of the Gobelins tapestry works, published in 1839 a great many rules or laws of harmony which are merely detailed developments of those above. Unfortunately all such results as these are debatable, for the question of a good or bad combination depends on the individual's training and susceptibility; if he has been taught either explicitly or by his environment that this or that is bad he is likely to believe it. Association also is not without influence; "loud" clothes are considered incompatible with dignity and gaudy wallpaper is regarded as "cheap," Southern or Oriental. In consequence of this we have the strange fact that brightly colored things more often than not cost less than those more delicately colored although so far as color and design are concerned the difference in cost of production is negligible. If the prices of, say, wallpapers were reversed — the cheaper being made the more costly — it is safe to predict that a noticeable reversal of taste would take place. Other important factors which determine the beauty of a color scheme are texture of surface, quantity, composition and design; thus silks, on account of their lustre, may be handsomer than cottons, but the same hues in crayon, because of their lack of shine, may be better than in oils. Moreover, the difficulty with rules of taste is that they tend to create and thus to trammel it. Many interesting illustrations of actual color schemes are shown in Vanderpoel, 'Color Problems.'

Strong contrast in colored signs and signals is not as closely related to legibility as might be expected. Observations on advertisements led to the following results which are arranged in the order of decreasing legibility; it is possible that they are influenced somewhat by personal equation (*Scientific American Sup.* 2 Feb. 1913): Black on yellow, green on white, red on white, blue on white, white on blue, black on white, yellow on black, white on red, white on green, white on black, red on yellow, green on red, red on green. COLOR IN ANIMALS. See COLORATION PROTECTIVE.

COLOR-BLINDNESS, *Achromatropsia,* popularly known as *Daltonism,* a singular affection, producing an inability to distinguish one color from another, and in certain rare cases to discern color at all, the eye perceiving only light and shade, or black and white. Although recognized for centuries, its modern study dates from the time when the famous English chemist, Dr. Dalton, brought it into notice by publishing in 1794 an account of his own case as marked by this peculiarity. More recently, Dr. George Wilson of Edinburgh also examined minutely into this phenomenon, and collected many striking instances. From the result of these investigations it would appear that color-blindness is much more common among men than among women, and that of the former 1 in 20 is unable to discern the nicer shades of color, and 1 in 50 to distinguish certain primary colors from one another. The colors most liable to be confounded are red and brown with green, purple and green with blue, red with black, light hues of all sorts with white, and dark shades with black. Color-blindness may be either congenital or acquired. The latter is believed to be an affection of the optic nerve and retina, may result from disease or accident and may be caused by the excessive use of tobacco, alcohol or other drugs. It sometimes happens that persons having contracted color-blindness may be able to distinguish colors accurately when they are near at hand, while they are not able to do so when they are at a distance. Congenital color-blindness is frequently hereditary and generally exists in both eyes. Sometimes it exists only in a slight degree, at others it is found in a marked degree, while in others it is complete; generally, however, it is only partial; that is, the person affected fails to distinguish properly one or two of the fundamental colors, red, green and blue. Based on these known facts and on extended investigations and experiments, several theories have been advanced to account for and explain color-blindness. One of these, the Hering theory, maintains that the retina contains three pairs of visual materials, namely, white-black, red-green and blue-yellow. According to this theory color-blindness results from one or more of these materials. The Young-Helmholtz theory, on the other hand, maintains that there exist in every normal person three primary

perceptions, red, green and violet, in the absence of any one of which the sense of color is defective; and the resulting missing color seems to be composed from the others. This theory is based partially on the fact that the most common forms of color-blindness are green, red and red-green blindness. Various tests have been arranged for the detection of color-blindness, the best of which are those devised by Professor Holmgren of Upsala, Sweden. They consist of skeins of wool of certain «test colors,» including various tints and shades of the same colors. These the person under examination is required to match.

Very stringent laws have been passed in most modern civilized countries to prevent color-blind people from occupying positions where their defective vision might endanger the lives of others. Sweden was one of the first countries to make laws for the protection of the traveling public against the danger arising from the employment of people affected with color-blindness in the railway service. As early as 1877 a law was passed in Sweden requiring that only people of normal vision for color should be employed in the railway service of the country. In the United States, Great Britain (and all her colonies), Germany, France, Italy and Austria provisions of some kind have been made to protect the traveling public from the danger of color-blind employees in the service of the railways. Consult Holmgren, 'De la cécité des couleurs' (1877); Thompson and Weiland, 'Detection of Color-blindness' (in 'System of Diseases of the Eye,' Vol. II, by Norris and Oliver, Philadelphia 1897); Posey and Spiller, 'The Eye and the Nervous System' (Philadelphia 1906); Eldridge-Green, 'Color-blindness' (1911); Abney, W. de W., 'Researches in Colour Vision and the Trichromatic Theory' (1913).

COLOR PHOTOGRAPHY. Photography is fundamentally colorless. This was discovered as soon as the first photograph was developed, and it was a great disappointment, for it had been hoped that light would reproduce itself, in both form and color. The search for a method which would «capture an image» was stimulated by the «light picture» in a camera obscura, for this image was a detailed miniature of a scene, and it was in color. It was the same kind of image that we see when we look at the focused picture on the ground glass of a modern camera. Small wonder that a way was sought to capture it. When, after many discouragements, successful photographic principles were evolved, the pictures excited world-wide praise. The details were sharp and the chemistry of the process rendered a variety of tone values, but they had none of the colors of nature.

Light, and Color Waves.—Light is given us in the form of a continual stream of waves or vibrations. Photography is the action of these waves on a photographic emulsion of silver combined with other chemicals. These waves give us the sensation of color vision, but light waves are not «color» to a photographic plate. Light waves vary in length, and these variations give the effect of colors in vision. While infinitesimally small, these waves have been measured, and they respond to control according to their wave length. Control of a light beam is accomplished in various ways: The complete beam, with all of its separate waves intact, can be projected, as with a lens, or reflected as from a sheet of white paper. It can be refracted, and split into component beams of different wave lengths, as when it is passed through a prism. It can be filtered, and some of its waves absorbed, while others are transmitted, as in a stained glass window.

Light splitting, or dispersion of the color waves, is beautifully demonstrated when the atmospheric conditions after a rainstorm cause the sunlight to separate into «the colors of the rainbow.» In the laboratory, the device for doing this is the «spectroscope,» and the band of dispersed light, showing its array of colors, is the «spectrum.» This band is a parade of wave lengths, arranged in the order of their sizes, and they are visible to the eye as: Violet, Indigo, Blue, Green, Yellow, Orange and Red. They are always in this order, spectroscopically, and their visual colors are directly related to their wave length.

There are many other manifestations of color and light control, but we have lived with them for so long that we accept them without much analysis. A beam of unrestrained sunlight is a terrific strain on the eyes. We seek shade from it, we wear sun glasses which absorb the «dazzling» waves; we turn from glaring white walls to green fields, in which all but the more restful wave lengths have been absorbed. Our whole scheme of light and color is founded on the fact that matter of all kinds, from the moisture in the air, to the flowers in our gardens and the minerals in the ground, has been invested with the powers of Absorption, Reflection, Refraction and Transmission of light waves. Light is a magnificent paint box, presenting its assortment of waves, alike to all substances, that each element, or combination of elements may choose its identifying wave colors. And they choose with unerring precision. The dispersion band of the spectrum, with the help of a telescope, will tell us the stuff of which the stars are made.

Photography and Color Waves.—Light has many assignments, other than stimulating vision, and one of them is demonstrated in photography. The effect of light on a photographic emulsion is to so change the set up of its components that they can be chemically developed into visible densities. These densities vary proportionately to the intensity and wave length of the light involved. It is a play in two acts. The first results in what is called a «negative image.» The more intense or active waves create a more dense image of developed silver salts, while the less active waves create a lesser density. A negative is really a density mask, and when it is held to the light for visual inspection, its different densities hold back more or less of the light, and give the eye a sensation of tonal variation. In the second act a print or positive is made from the negative. This also is a photographic operation, much like the first, in principle. It requires that light be transmitted through the negative to the new emulsion. Variations in negative density will control the amount of light which will be permitted to act in making the «print» and a positive image will be formed, reversed from the tone values of the negative.

The light waves which are primarily responsible for these reactions in the sensitive emulsions are not «colors,» because the photographic

COLOR PHOTOGRAPHY

plate has no retina, no brain and no color experience. They are colors to the eye, but to the chemical compounds they are simply active vibrations.

The Three Color Process.—Color finds its way into photography from a separate source. It is called the «three color process,» and it is a method whereby multi-color effects can be produced by combining three special colors, familiarly called yellow, red and blue. There is a touch of color magic in mixing three colors and producing the effect of many others, even though it is merely another manifestation of the use of light waves. The colors used however, must be technically correct, each representing about one-third of the spectrum. In the aggregate these colors will comprise practically all of the wave lengths of white light, and, in theory, they can be combined to reproduce any other color. But in practice, the result is not unlike comparing the music of three well-played instruments with that of a symphony orchestra.

The three colors of the tri-chromatic process are: Lemon Yellow (green-yellow); Magenta (blue-red) and Peacock Blue (green-blue). For convenience they are called «Process Colors.» When these colors are combined, they appear to «make» other colors. Yellow and blue, for example, seemingly make green, but as green is one of the primary colors of light, it cannot be «made,» for it already exists.

Process yellow is a green-yellow. If it is applied in the form of a transparent film of ink or paint, like water color, to a sheet of white paper, it will transmit only the green-yellow waves and absorb all the others from the white light which the paper reflects. If a process blue, a green-blue film, is superimposed on the yellow, only the green waves common to both films will be visible. No blue waves are available for this second film to transmit, as they have already been absorbed by the yellow. This is a subtractive process and can be carried to completion by adding a film of process red to the yellow and blue. This film will not transmit green, so this color also becomes absorbed; all the waves of white light reflected by the paper have been absorbed in three stages, and the result will be black.

When process colors of less than full strength are combined, the subtractive action will be less and transmission will be greater, which is simply another way of saying that more of the white wave combinations from the paper will be passed along to the eye. Consequently a «light yellow» and a «light blue» will create the effect of a «light green,» that is, spectrum green plus other waves which are in white light. These three process colors lend themselves to the effect of a great many different tones and combinations. If the colors are correct and the light source and paper are white, extremely colorful results will follow.

Color Separation.—Having three colors with which multi-color effects could be produced, the pioneers in photographic research had to find a way to adapt photography, so that it could use this color principle. When a photograph is made of any subject, under ordinary conditions, all of the color values are recorded on one negative. But as no way has yet been found to separate these intermingled values, once they have become established on a single plate or film, photography had to be changed into a three-color process. By using three different color filters and making one negative through each, the color values of a subject could be separated into three basic groups, and as a consequence, one negative recorded all of the values of process yellow; the second negative was a record of all the process red, while the third carried the values of the process blue. These were «separation negatives.» But at the time these were made, there was no way of making photographic prints from them in the process colors. So the photo-engraving process was called upon; a set of three printing plates was made from the three negatives, and each was printed with one of the process colors, superimposing them in register. The result, while not a photographic print, was a color print from photographic color separations, and offered hope that color, solely by photographic methods, was not far away.

Color Filters.—Color filters, so called, function in ways which border on the mysterious. Sun glasses have been referred to, as a type of filter; they absorb certain irritating rays of sunlight, permitting less harmful waves to pass into the eyes. This absorbing process is not easy to understand, because we are prone to make comparisons, and any substance which has been absorbed is considered to have been stored away, like water in a sponge. Or perhaps we visualize a few drops of ink in a glass of clear water; tangible evidence of absorption. But when light filters absorb colors, these cannot be seen, like ink in water. Absorbed colors vanish; not only to the eye but to the photographic plate as well. No visual change is apparent in a filter, which still retains its power to transmit the colors of light which have not been absorbed. Whatever the cause, the effect is what makes it possible to photograph color regions of a subject. There are many types of filters used in photography, the most common being a «cloud» filter. This is usually a light yellow, which absorbs some of the blue in a sky, restraining it so that it will not act so intensely. This results in a darker tone for the sky, while white clouds pass through the filter with more intensity. This is a mild form of color separation and increases the contrast between clouds and sky.

Filters for three-color work operate on this same principle, but they are more dense than cloud filters and so have greater absorbing powers. Their colors are determined with relation to the printing colors and are said to be «complementary» to them. This means that the light waves represented in one of the process printing colors, plus the waves in the complementary filter color, represent the complete spectrum of all color waves. Process filter colors are: Violet (red-blue); Green (yellow-blue) and Orange (yellow-red). It will be noted that each filter color is a combination of two printing colors. In action each filter transmits its own two colors and absorbs the third, or complementary, color. The transmitted light builds up density in the negatives, when they are developed, and negative density means that there will be corresponding reversed values in the print. This action takes place when colors are isolated, or combined; when they are solids, or tones, and the result is called «color separation.»

Color separation can be more readily understood if one will visualize a color chart com-

posed of three discs of solid printing colors—one yellow, one red and one blue. The violet filter will transmit both the red and the blue, and the density, developed in the areas representing these two colors in the negative, will prevent any action by light when the print is made. The yellow disc, however, which color is absorbed by the violet filter, will appear as a transparent disc in the negative and this area can be printed. When the print from this negative is transformed into a yellow image, it will be a reproduction of the yellow disc of the chart. The green filter will transmit the yellow and the blue, so its print will be a picture of the red disc. The orange filter, transmitting yellow and red, will produce a picture of the blue disc. In every instance, the image from a separation negative represents the color which is complementary to those which were transmitted by the filter.

When the subject to be photographed is a more complicated combination of colors; when the yellows, reds and blues are combined in various proportions, the filtering process takes care of them automatically. Instead of complete absorption in some area, it will be partial. All of the photographic properties of the emulsion will be called into use, as though the final image were to be a mono-chromatic picture with a full range of tone values. Each filter will designate the color regions on which the emulsion is to work; each negative will have its correct densities for the selected color regions; and when the prints from the separation negatives are each in their respective printing colors, they can be combined to reconstruct the image which was separated by the filters.

Three Color Photographic Prints.—A number of years elapsed between the first print in color by way of the printing press, and actual photographic prints in colors. The photographic method became a reality with the introduction of a process known as the «carbon tissue» method. The material was paper, coated with a film of gelatin, which previously had been impregnated with pigment color. It is still used, and for process color work the sheets are impregnated with the process colors—one yellow, another red and a third blue. The material is made sensitive to light by the addition of a sensitizing chemical, and, when exposed to light, the gelatin becomes hardened, proportionately, to the light intensity transmitted by the negative. When developed in warm water, the unhardened, soluble gelatin washes away, leaving an image which is in the color of the pigment previously mixed with the gelatin. Prints made from the three negatives, in their respective colors, can be stripped from the original paper bases and mounted on a permanent sheet, one on top of another. The procedure, including the accurate registration of these three separate images, calls for skill and patience, but it works.

Commercial Application of Color Processes.—There are a great many different applications of the three-color process of color separation and printing. They are grouped in two classes: «Prints» and «Transparencies,» the latter being technically known as «Positives» or «Diapositives.» Transparencies are probably the easiest processes for the photographer, but they represent a very complicated manufacturing technique for the producers of the plates and films used. Lumière was the first to market a commercially successful color plate for transparencies, which could be used by any one, and in an ordinary camera. It is called the «Autochrom,» and it requires but a single exposure. This may appear to be a contradiction of the explanation that all color photography requires three negatives, but Lumière got around this difficulty by making it possible to obtain the three necessary color exposures on one plate.

The process uses filters of the conventional colors, but in the form of tiny grains of dyed starch. After preparing and dyeing them in three separate lots, one Violet, another Green and the third Orange, they are thoroughly mixed in equal proportions and applied to an adhesive film on the glass plate in such a manner as to form a color screen composed of equally distributed filter colors. After protecting this color screen with a waterproof varnish, it is then coated with the color sensitive emulsion, and exposed in the camera with the color screen facing the lens. Consequently the image has to pass through the screen filters, before reaching and acting upon the emulsion.

While this method is color separation through the three filters, each separation «negative» is but the size of one tiny starch grain. Employing special chemical treatment after development, the image is transformed from negative to positive, thereby becoming a transparency of full photographic values, plus the colors supplied by the starch grains.

This process is one of the many which takes advantage of the limited resolving power of the eye. Grains or dots, too small to be recognized as separate units, are accepted in their aggregate and, to the sense of vision, are tones and color continuity. It is worth noting that every grain of filter color in this Autochrom screen serves two purposes: First, they separate the colors of the subject for photographic purposes, and then they permit themselves to be seen, in their alotted spaces.

There are several processes in the transparency group; the Agfa, which has a granular screen quite similar to the Autochrom; Dufaycolor, which is a flexible film, but on which the color screen is a very fine mosaic instead of an unsymmetrical arrangement of grains; and the Finlay.

In the Finlay method, the color screen is not integral with the color plate, but is on a separate glass. It is placed in contact with the sensitive plate in the plate holder, and the exposure made through it results in the usual minute color separations; but the plate is developed and fixed as a negative, after the color screen has been removed. The Finlay screen is also a symmetrical mosaic of color elements, and when transparent positives are made from the negative, the mosaic image on the negative becomes duplicated in symmetry on the positive. Color is supplied by the use of a viewing screen, which has identical color arrangement, and which can be registered with the transparency. As these viewing screens can be purchased in quantities and matched up with additional positives, duplicate color transparencies can be obtained from one negative. As yet there is no way of duplicating the color plates made by the other three processes, except to rephotograph them on one of the screen plates or make color separations and prints from them.

Additive and Subtractive Processes.—The use of the filter colors, Orange, Green and Violet, to obtain visual color combinations in these transparency processes, is based upon the principle of «juxtaposed» or side by side color elements. It is known as the «additive» process. Its name describes it well, for the colors which have become separated by the filter elements become added together again, in the eye, but it is only effective when the color elements are juxtaposed. When the three filters are used separately, as in the conventional color separation method, each exposure results in a separate negative. Prints from these negatives must be combined, and as there is no way known whereby accurate juxtaposition of color elements can be achieved from separate prints, they have to be assembled by superimposing them. Handled in this manner, accurate registration is relatively easy, but the superimposing of color films, brings the subtractive color process into the picture. The colors used, therefore, must be «Process» yellow, red and blue.

There is still another transparency process, Kodachrome. It is the only one of the group requiring laboratory development and processing. It is a subtractive, not an additive method. The films consist of separate layers of color sensitive emulsions and filters. Development requires special reversing and dyeing treatment, so that one layer of film will be yellow, another red and the third blue. There is no color screen; separation being obtained by the color filters which lie between the film layers, plus special «regional» sensitizing of the emulsions. The absence of a color screen makes these color films extremely luminous. (When colors are superimposed, the fact that one is «added» to another, has no connection with the use of the word «additive» as applied to the process of juxtaposed colors.)

Although these color photographs are transparent, they cannot be used for making prints by any known direct process, because they are positives. Prints from them would be negative. However, there are indications that a solution to this problem may be forthcoming and, if it does become available for general use, color prints on paper may be rather simple things to make.

First among the processes of the subtractive group is the old one of making three separation negatives, one at a time, in an ordinary camera. When using this method the fact that the exposures are made at distinct intervals, requires that the subject be definitely still. Even flower groups are poor material for this process because conditions frequently cause some leaf or blossom to change position, and if this happens before all three exposures are made, the set will not register. To help this situation, cameras are made which have sliding backs, for quick plate changing, but even with this device there is elapsed time between exposures.

An ingenious contrivance for making the three separation exposures simultaneously is known as the «one shot» camera. Three plates (or films) are used, two of them being placed face to face, and the third set off at an angle. The placing of the color filters varies with different makes of apparatus, as does also the position of the plates, but the principle is to divide the image by reflection, after it comes through the lens, sending it along the two paths leading to the sensitive plates. This is done by a mirror which is transparent and which will reflect the image in one direction and transmit it in another. This mirror can also be a filter. The whole arrangement is extremely ingenious and is not nearly so complicated as its description would indicate. It has made it possible to expose the three separate plates simultaneously, and with suitable illumination, instantaneously.

Color Prints on Paper.—Color printing by photographic methods has been materially improved since the introduction of the original carbon tissue process. One of the new techniques is called «carbro,» a term derived from «carbon» and «bromide.» It utilizes the sensitized and pigmented gelatin of the carbon tissue process, but exposure on them is not made directly from the negatives. Bromide prints or enlargements from the separation negatives are made first to any desired size. When these are placed in wet contact with the sensitized sheets of gelatin the effect is the same as though the printing emulsion had been exposed to light. Contact with the silver image in the print hardens the sensitized gelatin. Development of the sheets and superimposing of the three-color prints follows the usual procedure.

«Chromotone» is another printing process, using separation negatives, but the material is not impregnated with a pigment. The emulsions are sufficiently light sensitive to permit their use for direct projected enlargements, one from each negative. Color in the respective prints results from the use of special chemical treatment which changes the silver of the prints into new forms and colors. Thus one print can be chemically developed into a process yellow, another as the process red and the third as a process blue. The separate color prints are then stripped and superimposed in register, as in the carbro process.

A third process, called «wash-off relief» can be used by direct projection of the separate images, as in Chromotone, but the color comes from a special dyeing process. When the exposed image on the paper is developed it will have slight variations in thickness. Unexposed areas «wash off,» and the variations in thickness will be proportionate to the exposure in different areas. When one of these prints is dyed, its acceptance of the color is also proportionate to its variations in thickness, and a color image results. To make a complete color print, the separate dyed sheets are brought into contact with a specially-prepared paper base, which absorbs, or «imbibes,» dye color from them. The yellow is laid down first, then the red and finally the blue, and the color image will all be in one plane, not in separate layers. This process is, in effect, a color printing process, using dyes instead of printing inks.

It is possible to produce transparencies by modification of the subtractive process. If the color sheets are on a transparent base, instead of one which is opaque, they can be combined by the usual methods and will present a color effect quite similar to Kodachrome. It is also possible to obtain a variety of color effects, which, while they will not be color reproductions, will be colorful creations. This can be done by changing the printing colors, or the filters, or both. Very interesting results can often be obtained by using two, or four colors,

instead of three. It is an open field for those who like to experiment.

In Conclusion.—This description of the principles of color photography has, of necessity, been made brief. Only outlines of the processes and methods have been given. In practice, it has become quite complicated. No mention has been made of the trials and tribulations of the color worker, due to innumerable factors which may make or break a fine print. Experience, and a very helpful attitude on the part of supply houses and color laboratories, to say nothing of the exchange of ideas between workers, has advanced the process rapidly during the past few years. In fact, from the very beginning, progress has been a divided achievement. In the appended chronology only important dates and accomplishments have been given, but these also represent ultimate success with some phase of the process, for which credit might well be given to more than one person.

CHRONOLOGY, AS RELATED ONLY TO COLOR IN PHOTOGRAPHY.

1722. Three-color prints made from hand engraved plates, by Jacques Christophe Le Blon.
1727. Simple image obtained by action of light on white chalk and silver nitrate. Impermanent. Johann Heinrich Schultze.
1839. First permanent optical image on sensitized metal plate in a camera obscura. Louis Jacques Mande Daguerre (1787–1851), and Joseph Nicephore Niepce (d. 1833).
1855. Demonstration of three-color photography with filters. Imperfect, probably for want of completely color-sensitive emulsions. J. Clerk Maxwell (1831–79).
1873. Greatly-increased sensitivity to colors, by addition of dyes to emulsions. Herman Wilhelm Vogel (1834–98).
1881. Three-color prints from halftone plates. Frederick Eugene Ives (1856–1937).
1891. Interference color photography. Beautiful and extremely accurate, but too difficult of manipulation. Gabriel Lippmann (1845–1921).
1907. Lumière Autochrom. Based on the juxtaposition of colors suggested by Louis Ducos du Hauron in 1869.
1936. Kodachrome. Screenless, subtractive, transparency process. Eastman Kodak Co.

HARRY A. GROESBECK, JR.,
Beck Engraving Company, New York City.

COLOR IN PLANTS. The prevailing color of vegetation is green, owing to the presence of *chlorophyll* in all external tissues not turned to wood or bark. This is a green substance produced in and necessary to all the growing parts of plants exposed to sunlight; but the flowers and fruits of many families as well as the whole form of seaweeds, lichens and fungi, often exhibit brilliant hues; and some lowly groups, as the molds, etc., are white, or nearly so, because they do not contain chlorophyll. Chlorophyll is green because, as the spectroscope shows, it absorbs the red and blue rays in the sunlight, and leaves only the remainder of the visible rays of the spectrum to come to our eyes, and these, in combination, affect us with a sense of green. The red and blue rays stopped by the chlorophyll are the ones useful to the plant, for it is only their vibrations that are able to break up the carbon dioxide breathed in by the plant-leaves, and to separate its constituents into sustenance (carbon) and waste (oxygen). Chlorophyll, then, is not a true pigment, although it produces the most universal color in nature.

Many leaves and other surfaces of plants do contain, however, a true, reddish pigment, sometimes so abundantly as to redden a whole part or even an entire plant, as is seen in seaweeds. The excessive development of the property by artificial cultivation gives the gardener such gay vegetables as red cabbage, the gaudy foliage-plants, and such shrubs or trees as the copper-beech. This red pigment is *erythrophyll* (or *anthocyan*), and when dissolved out in hot water it shows a beautiful rose tint. It appears strongly in leaf-buds as they begin to shoot forth in spring, and in the earliest of the growing twigs that in March give a ruddy tone to thickets in advance of the leafing. Several explanations of its supposed usefulness to the plant have been offered, while others treat it as merely a chemical incident of no particular utility.

The same sort of red reappears in the rich colors that beautify our woods in autumn, when there also becomes strongly manifest in the «turning» leaves another coloring-matter, the bright yellow pigment, *anthophyll,* which is always present in plants, but in very minute quantity. These reds and yellows show themselves plainly in the fall because stimulated by chemical reactions as the chlorophyll disappears with the slow decay of the leaf; and their presence seems to have little if any utility in the economy of the plant.

Turning now to the variegated and often vivid coloring of flowers and fruits, we enter the domain of the relation between plants and insects. The blossoms of primæval vegetation seem to have been virtually colorless, and this condition persists in those, like the grasses, etc., which are fertilized by means of the wind. Night-blooming flowers, and those growing in shaded places, are usually white—the most conspicuous hue in a dusky light. Most flowers, however, are now more or less brilliant in color, and there is evidence that this is a characteristic that has been gradually acquired, along with other characteristics, the effect of which is to increase the likelihood of the flowers being visited by insects, and thus obtaining an exchange of pollen with other plants of the same kind. Colored flowers become conspicuous amid green leaves, and, aided by odor, serve as signs of the presence of the sweet food (nectar) that insects seek and must have. Many simply-constructed blossoms have only a uniform tint, as the plain yellow of the evening primrose; but more, probably, have a complicated structure and are varicolored, especially in a striped way on the inside of the corolla. It is found that in these cases the lines of color lead straight to the nectary and thus indicate the pathway for the insect to follow. The benefit to the plant is, of course, that by following that route the insect is sure to deliver any pollen it may have brought, and will be dusted with more for delivery to the next blossom visited.

ERNEST INGERSOLL.

COLOR PRINTING, the art of reproducing pictures, designs, letterpress, etc., by any of the processes of printing, in two or more

colors. It may be divided into—(1) primitive color printing, as Japanese brushwork from color blocks; (2) chromolithographic printing, in which colors are superimposed by lithographic processes (see LITHOGRAPHY); (3) offset printing in colors (see PRINTING); (4) typographic color printing, done from type or relief plates, by typographic mechanisms. As a subdivision of typographic color printing, the tri-color process of reproducing in natural colors by photo-engraving forms practically an art by itself.

Japanese Color Printing.—The modern survival of primitive color printing is found in the brushwork from color blocks produced by the Japanese and Chinese. These are sold for a small price in the shops of Eastern cities. They represent the combined work of an artist, engraver and printer. The artist makes a brush drawing on paper of local manufacture produced from rice or bark fibres, laying on the color in masses. The engraver pastes this color drawing on a printing block, usually made of wild cherry (*Yamazakura*) wood. With chisels and gouges rudely resembling the tools of the Western wood engraver, he cuts the main outline of the design on the wood, thus making this the key-block of the resultant picture. In cutting the block into relief he destroys the drawing, but the body tints show on the wood, to guide him in engraving blocks for the other colors. A proof of this first key-block is taken on paper, and transferred to another block, on which the red portions of the picture are reproduced. A blue and a yellow, and perhaps other color blocks, are produced in the same way. Register or correct superposition is secured by cutting an L nick in one corner of the proof of the key-block, and of all reproductions, so that they can be laid in similar position on all the blocks of a series. To prevent the blocks from warping, dovetailing is employed. The printer takes the set of color blocks, and with dampened bark paper proceeds to printing, one color at a time, inking the block with a brush, dexterously laying on the sheet with the L nick to secure accurate position or register, and impressing the sheet on the block by rubbing, in a manner somewhat similar to the taking of a burnished proof by a modern engraver. The rubber is a ball of hemp thread. Ground vegetable and mineral substances are used for color pigments. When all the colors are on, a wash of rice paste is sometimes added to give a brilliant effect. By such primitive methods the Japanese printer can produce about 100 to 125 impressions per hour. If the pictures are in four colors, he can thus print 25 to 30 complete copies per hour.

Two-Color Printing.—This is accomplished typographically, either by two separate printings, as in black and red ink; or by the use of a two-color press, on which the sheet is fed first to a form inked with one color, and then to a second form inked with another color. Thus the two colors are produced at one operation though not simultaneously. Booklets and circulars, and sometimes sections of magazines are now commonly printed in two colors rendering them more attractive. Duographs, or half-tones in two colors, are produced by this method. The modern occidental methods employed in color printing are described in COLOR PHOTOGRAPHY; PRINTING (qq.v.).

COLORADO, kŏl-ō-rā'do, **the «Centennial State,»** admitted to the Union 1 Aug. 1876, is bounded north by Wyoming and Nebraska, east by Kansas and Nebraska, south by New Mexico and Oklahoma, west by Utah; area, according to the remeasurement made for the 1940 census, 104,247 sq. m.—104,967 sq. m. land and 280 sq. m. inland water. Capital, Denver.

Topography.—Eastern Colorado, one-third the total area, is the westernmost portion of the great treeless plains that continue the Kansas prairies. Near the abrupt rocky faces of the mountains, they rise in low sharp-ridged foothills, called "hog-backs," composed of an extensive series of fresh water and marine formations (remnants of the junction of sedimentary with primary rock). The remainder of the State belongs entirely to the Rocky Mountain system. The Front Range connects the plains with the main range of the system. The western portions fall in minor slopes toward the Pacific. Colorado contains the greatest mass of high land in the United States, if not on the continent.

The main mass of the Rockies crosses Colorado in two principal lines of elevation. The eastern, or more recent line, is composed of the Medicine Bow Range, which extends into Wyoming; the Front Range, the one first encountered by the early immigrants and still crossed by the main line of transmontane travel, the Sangre de Cristo and the Culebra. The western, or main line, is composed of the Park Range from the north and the Sawatch Range, which is a continuation of the Sierra Madre of Mexico. West of these main lines lies a complicated series of broken ranges and plateaux, parallel, lateral and oblique, but with a general trend northwest and southeast. Of these the principal ones are the Roan or Book, north of the Grand River in the extreme west; the Uncompahgre parallel to the Gunnison River on the south; the San Miguel further south; the San Juan to the east; and the Elk near the centre obliquely to the Sawatch (incorrectly spelled Saguache). The Elk is a very notable range about 30 miles long, geologically interesting from the extraordinary displacement of strata, with a number of lofty and rugged summits; Castle Peak, 14,259 feet; Maroon, 14,003 feet; Snow Mass, etc.

The best-known peaks in the State, Long's (14,271) and Pikes (14,108), noted landmarks of the immigrant trail, are in Front Range, which also contains Audubon, Arapahoe, James, Rosalie, Grays (14,341), Torreys (14,336) and Evans (14,330). The loftiest range, as a whole, is the Sawatch, a granite mass over 13,000 feet high for many miles together and from 15 to 20 miles wide. Its peaks are Harvard (14,375), Princeton (14,196), Yale (14,187), and others. After a depression of 18 miles, the range rises in the Mountain of the Holy Cross, where a deep ravine and a transverse fissure outline a gigantic cross in the snow. The highest point in the State is Mount Elbert (14,431 feet).

The great passes are far higher than any mountain summits east of the Rockies. There are several over 10,000 feet above sea-level: Alpine (13,550), Cottonwood (13,500), Argentine (13,286), Marshall (10841), Tennessee (10,418) and Fremont (11,313).

Lying between the two parallel elevations

are four great parks which are separated from each other by cross ranges. By far the largest is San Luis Park, which extends into New Mexico and has an altitude of about 7,000 feet and lies between the Sangre de Cristo and Culebra ranges on the east and the Sawatch on the west and is more nearly level than the plains. It is nearly the size of Massachusetts. It is drained by the Rio Grande through the southern centre, while the mountain streams of the north flow into the San Luis Lake, the largest lake in Colorado. North of San Luis Park is South Park, between Front and Mosquito ranges, 8,000 to 12,000 feet high, and about the size of Rhode Island. Further north is Middle Park, still more elevated and somewhat larger. Lying between Medicine Bow and Park ranges is North Park, the second in size. There are many smaller parks, the most famous of which are Monument Park and the Garden of the Gods near Colorado Springs; in the latter "rise towers and pinnacles consisting of the vertical strata of the white Dakota sandstone and of the red triassic sandstone below. Some of these huge masses rise vertically for 200 or 300 feet, and serve as examples of erosion of steeply upturned strata of varying consistency. Lower white ridges of Jurassic gypsum or Cretaceous limestone afford strong contrast in color when compared with the red sandstone."

River Systems.—The main Rocky Mountains must obviously be the greatest of American watersheds and chief source of river systems, except Minnesota; they contain the continental divide between the waters flowing to the Atlantic and those flowing to the Pacific. One part of it is the southern boundary of North Park, the streams of which flow north to the Platte-Missouri-Atlantic system, those south of it feed the Colorado and the Pacific; another is between Creede and Ouray, separating the headwaters of the Rio Grande from those of the Gunnison and Uncompahgre of the Colorado system. The eastern plains are divided chiefly between the two great systems of the Arkansas and the South Platte; the former occupies more than one-half their area in the State, the southern portion; the South Platte, the larger portion of the northern half; between them on the east is a section draining into the Republican River, an affluent of the Kansas. The South Platte rises in South Park; the Arkansas in the mountains west of it, Leadville lying on one of its head creeks. Except for these and the Rio Grande in San Luis Park, the mountain section is almost entirely drained by the Colorado River system, which includes the Yampa (or Bear) and the White in the northwest, flowing into the Green, and the Gunnison and the Dolores flowing into the Colorado from the southwest.

Of equal fame with the giant peaks and even greater beauty are the stupendous mountain canyons through which its rivers cut their way. Western Colorado forms the eastern edge of what Major Powell has called the Plateau Province; and all the wonders and beauties of this remarkable region are found in Colorado. There are the terraced platforms, ending in rock faces dropping sheer upon other platforms hundreds of feet below, and ending in vertical gorges from 1,000 feet to a mile in depth, where the sand-laden currents with a steep fall have cut their channels through countless strata of brilliantly variegated sedimentary rock; here are barren mesas, and cool grassy forested levels and slopes above the plane of perpetual drought where the mountains bar off the vapors; rock headlands around curves or junctions of streams or gullies, fantastically carved in striking likeness to the work of human architects. The canyon of the Grand, the Black Canyon of the Gunnison, the Royal Gorge, a part of the Grand Canyon of the Arkansas, are famed for their beauty and their grandeur.

Climate and Rainfall.—The dry, cool, thin air of mountainous Colorado makes its accessible eastern portions, especially the parks, widely famed as sanatoriums for patients with asthmatic or pulmonary diseases. Colorado Springs, the Rocky Mountain Saratoga, was built up by Eastern invalids. The summer days are sometimes hot, but the dry air and bare rocks cause so rapid a radiation that the nights are always cool and dewless. There is little severe winter cold, zero being rare; the frost season is short, and the snows, seldom deep, soon melt, except on the mountains. The January mean temperature for the leading places is about 28.5°F.; the July 72° to 74°F. The average rainfall is 14.8 inches, fairly even through the State, though naturally much heavier on the higher levels, varying from nearly 30 inches at Pikes Peak to 12 inches at Las Animas in the Arkansas plains. Hence, agriculture can be carried on without irrigation in many mountain regions, though better with it.

Agriculture, Stock Raising and Irrigation.—Despite the output of its mines, agriculture and stock raising are by far the most important industries of Colorado, both as to returns to producers and as to the number of persons employed. Besides the staple crops—hay, grain, etc.—the state is a large producer of such vegetables as peas, beans, tomatoes, cucumbers and the like, large quantities of which are canned and shipped to all parts of the United States. Colorado is the leading producer of sugar beets and beet sugar among the states of the Union. It is also a large producer of apples, cherries, pears, peaches, apricots and other fruits. Stock raising is extensively engaged in, especially the raising of cattle and sheep.

Because of the low rainfall in most arable sections of the state, irrigation is essential to the profitable production of farm crops, and irrigation early assumed important proportions. Under the Colorado law, the waters of the streams belong to the public, but may be appropriated for beneficial use. An appropriation, approved by the courts, is equivalent to actual ownership so long as it is used beneficially. Under this system, many thousands of water decrees have been awarded farmers and ditch companies, and by 1940 water was being supplied by irrigation to approximately 3,500,000 acres throughout the state. The various irrigation projects, collectively, have cost close to $175,000,000, and comprise around 800 reservoirs and between 15,000 and 18,000 miles of main canals. The irrigation projects include the Uncompahgre, in Montrose and Delta counties, and the Grand Valley project in Mesa County, constructed by the United States Bureau of Reclamation. The two projects represent an expenditure of about $15,000,000 and irrigate an area of approximately 87,000 acres. The cost of the projects is to be repaid by the land owners in 40 equal annual instal-

ments, without interest. Another great federal project is the Colorado-Big Thompson which will cost, when completed, approximately $44,000,000. It is designed to impound the surplus waters of the Colorado River in a series of reservoirs and carry them through a tunnel over 13 miles long under the Continental Divide to the headwaters of the South Platte River, from where they will flow down the valley to irrigate over 600,000 acres.

ACREAGE AND PRODUCTION OF SELECTED CROPS

Crop	1929–38 Average	1940
Corn:		
Acreage	1,382,000	888,000
Production—bushels	14,838,000	10,656,000
Wheat:		
Acreage	1,047,000	1,096,000
Production—bushels	12,947,000	13,560,000
Oats:		
Acreage	160,000	151,000
Production—bushels	4,460,000	4,530,000
Barley:		
Acreage	427,000	457,000
Production—bushels	8,096,000	9,368,000
Hay:		
Acreage	1,496,000	1,376,000
Production—tons	2,128,000	1,959,000
Beans (dry):		
Acreage	320,000	332,000
Production—bags	1,118,000	1,760,000
Potatoes:		
Acreage	99,000	78,000
Production—bushels	14,178,000	15,210,000
Sugar Beets:		
Acreage	182,000	140,000
Production—short tons	2,248,000	2,034,000
Apples:		
Production—bushels	1,517,000	1,564,000
Peaches:		
Production—bushels	1,159,000	2,000,000
Pears:		
Production—bushels	273,000	249,000

According to the 1940 census of agriculture there were 51,436 farms in Colorado, a decrease of 14.2 per cent over the number listed in 1930. The following table shows in detail the number of farms, farm acreage, value, land usage, livestock on farms, etc., in the state, as of 1 April 1940 with comparative figures for 1930.

Item	Census of 1940	Census of 1930
FARMS, FARM ACREAGE AND VALUE		
Number of farms	51,436	59,956
Farms operated by—		
Full owners	22,385	26,929
Part owners	9,442	11,497
Managers	471	838
All tenants	19,138	20,692
Value of farms (land and buildings)	$388,343,847	$629,346,675
Average value per farm	$7,550	$10,497
Average value per acre	$12.32	$21.79
All land in farms—acres	31,527,240	28,876,171
Average acreage per farm	612.9	481.6
FARM LAND ACCORDING TO USE (ACRES)		
Cropland harvested	4,769,671	6,750,398
Crop failure	1,559,191	858,052
Cropland, idle or fallow	1,684,793	840,234
Plowable pasture	4,885,034	4,214,777
Woodland	1,096,546	1,541,463
All other land	17,532,005	14,671,247
Land available for crops (Harvested, failure, idle or fallow, and plowable pasture)	12,898,689	12,663,461
LIVESTOCK ON FARMS (NUMBER)		
Horses and colts	212,350	325,037
Mules and mule colts	11,934	28,746
Cattle	1,144,213	1,281,276
Cows and heifers 2 yrs. old and over on 1 Jan. of census year	584,638	603,205
Cows and heifers milked	190,851	234,530
Sheep and lambs	1,681,380	2,234,300
Hogs and pigs	214,829	298,519
Chickens	2,842,061	3,653,054

Geology and Mining.—The main ranges, particularly the east range, have a core of schist and gneiss with an occasional area of granite. These main ranges are flanked on all sides with sedimentary rocks. In many cases, these rocks show practically all the geological epochs from Cambrian Quartzite to the Quaternary, while again the most recent is found resting on the most ancient. There are large areas of purely eruptive rock, such as the San Juan Range in the southwest and the Spanish Peaks, near Walsenburg. The prairie land is so completely clothed with soil that it is difficult to follow the geological skeleton, but it is probable that nearly all geological periods are represented in its formation. Great coal deposits are found in the upper Cretaceous, and most of the metallic deposits are found in igneous formations.

Colorado is rich in minerals of a wide variety. The output of its mines includes gold and silver ores, coal, lead and zinc ores, ores of the rare metals (uranium, vanadium, molybdenum and tungsten), gold from placer mines, manganiferous ores, clay, granite, fluorspar, pyrites, sandstone, gypsum, copper ores, and limestone.

The coal deposits are enormous, and include every variety of coal from lignite to anthracite. The output averages from 6,000,000 to 10,000,000 tons a year, and the area of the fields has been estimated by the United States Geological Survey at 18,100 square miles. Coal is mined in at least 16 counties. Mining was begun in 1864, with an output that year of about 500 tons.

Gold and silver are found in all but a few of the 63 counties. Cripple Creek field, in Teller County, is one of the most famous gold mining districts in the United States. That gold existed in what is now the State of Colorado had been known since 1806, but it was the discoveries of 1858, near the confluence of Cherry Creek with the Platte River, that started the famous gold rush of that and the following year.

Petroleum was developed in Colorado near Cañon City during the Civil War, and development of the fields in a small way began at Florence in Fremont County in the late 70's of the 19th century. Here oil is found in the crevices in the shale, and it is one of the few crevice fields in the world. Here, also, is located one of the oldest refineries in the West. The next development was at Boulder in the county of that name, but the output was small. Perhaps the next oldest development in the State was at Rangely, Rio Blanco County, in the northwestern part of the State. These wells were shallow and the production was light. However, oil did not become an important product until about 1924 or 1925, when the discovery of large quantities of oil and natural gas on the Wellington Dome, north of Denver in the vicinity of Fort Collins, led to the exploitation of the whole front range area of the Rockies. About the same time oil and gas in quantities were discovered in Moffat County in the northwestern corner of the State. The Moffat, Iles and Hamilton domes were the first opened up, and a pipeline was laid to Craig, the western terminal of the Denver and Salt Lake Railroad, and a refinery was built there. Thereafter the Hiawatha gas dome was opened up on the Colorado-Wyoming line, and a pipeline was laid to supply Salt Lake City and other towns in Utah and Wyoming. Gas and oil have been discovered in many other counties in the western and southwestern parts of the State. In Jackson County is

one of the most interesting oil and gas developments known. Drilling there developed production at the highest elevation (8,000 feet) of any oil and gas field in the United States. The product of the wells comes out in a solidified condition. The gas, which is carbon dioxide, is the so-called «dry ice» of commerce. During 1930 the first commercial production of oil on the great plains northeast of Denver was found in drilling on the Fort Morgan structure in Weld County. This was the first oil well drilled in the Julesburg Basin, comprising parts of Colorado, Kansas and Nebraska. In the western part of the State, and extending into the adjoining sections of Utah and Wyoming, are vast deposits of oil shales, which have been reported upon by the United States Geological Survey. These shale deposits contain the bulk of the future oil reserves of the country. The Government maintains a shale-oil experimental plant at Rulison, in Garfield County. In normal times production of oil averages between 1,500,000 and 2,000,000 barrels. In 1939, production was 1,391,000 barrels; in 1940, 1,350,000 barrels. In normal times the mineral output of the state averages from 60 to 70 million dollars annually. The output of specified minerals in 1940 was: gold, 368,798 fine ounces; silver, 9,559,762 fine ounces; copper, 24,592,000 pounds; lead, 22,378,000 pounds; zinc, 9,694,000 pounds.

There are a number of mineral springs in the State. Among the most famous are Manitou springs, Steamboat springs, Glenwood springs, Buena Vista springs, Ouray springs, Poncha springs, and Idaho springs. The latter are close to Denver, and Manitou springs are at the foot of Pike's Peak. These mineral springs are attracting greater and greater numbers of tourists and invalids every year.

Railroads.—There are approximately 5,000 miles of main track steam railroads in the State of Colorado. Several of the great trunk lines of America cross the State, while a number of short lines pierce to the heart of its mountain districts, thus affording excellent rail transportation facilities. The chief systems include the Atchison, Topeka and Santa Fé; the Chicago, Burlington and Quincy; the Chicago, Rock Island and Pacific; the Colorado and Southern; the Denver and Rio Grande Western; the Denver and Salt Lake, control of which by the Denver and Rio Grande Western was authorized by the Interstate Commerce Commission on 12 Dec. 1930; the Missouri Pacific; and the Union Pacific. Other railroads include the Colorado and South-Eastern; the Midland Terminal; the Rio Grande Southern; and the Manitou and Pike's Peak. The latter, opened in 1891, is a cog or rack railroad running from Manitou to the top of the peak, a distance of 8.9 miles, and is operated mainly for the accommodation of tourists. The Denver and Salt Lake Railway Company uses the Moffat Tunnel constructed by the Moffat Tunnel Improvement District Commission, and formally opened 28 Feb. 1928. This tunnel, begun in 1923, is 32,160 feet long and pierces the Continental Divide under the northeasterly slope of James Peak, 50 miles west of Denver, and, with the «Dotsero Cut-off,» opened in 1934, shortens the distance between Denver and Salt Lake City about 173 miles. It is a multiple purpose tunnel, designed for the use of standard gauge railroads, and, by means of a parallel service tunnel, for the transportation of water, electric current, and telephone and telegraph wires. During the winter months when the highway over the Continental Divide is blocked by snow, automobiles are transported through the tunnel on flat cars. On 6 Jan. 1926 the Moffat Tunnel Commission and representatives of the Denver and Salt Lake Railway Company signed a lease under the terms of which the railway company is to be permitted to use the tunnel for a period of 50 years with an optional right to renew the lease for an additional period of 49 years. The cost of constructing the tunnel was approximately $18,000,000.

Education.—The organization of the school system, the efficiency of teachers and the equipment of schoolhouses, places Colorado with the States that lead in educational affairs. Education is free for all persons between the ages of six and 21 years, and compulsory for all between the ages of eight and 16 years. Expenditures for educational purposes exceed $25,000,000 annually, while the enrolment in the public schools exceeds 250,000 pupils a year —over 60,000 being in the public high schools. The institutions of the higher learning include the following: the University of Denver (1864, M.E.), the pioneer institution of higher learning in the Rocky Mountains; Colorado College (1874, Congregational); University of Colorado (1877, State); Regis College (Roman Catholic, transferred from Las Vegas, N. M., in 1884). The State supports the School of Mines at Golden, ranking among the best in the world, and the State Teachers colleges maintained at Greeley, Gunnison and Alamosa. The College of Agriculture and Mechanic Arts at Fort Collins has a large student body doing excellent work. Its experiment station has attracted the attention of the world by its cross-breeding of animals and plants. The University of Colorado maintains a medical school. There are many private schools in Denver, Boulder, Cañon City, Leadville and other cities of the State. In Denver the Baptists maintain the Colorado Women's College.

State Government.—The constitution under which the state is still governed was adopted 14 March 1876, and is notable for the detailed manner in which it vests all political power in the people and enumerates the particular rights of the individual. Social and economic readjustments have necessitated many changes in the constitution, and the process of amendment has been often resorted to. The governmental structure is of the familiar three-branch type—executive, legislative, and judicial. The executive branch includes the governor, secretary of state, treasurer, auditor, attorney general, and superintendent of public instruction, each elected for a two-year term. The legislature, called the general assembly, is a bicameral body, and meets biennially in odd years on the first Wednesday in January. However, both statutory laws and constitutional amendments may be initiated by the people. The judicial branch of the government is headed by the Supreme Court consisting of seven members. The state is divided into 14 judicial districts, with 26 district courts. There are also 63 county courts, and below them are the justices of the peace. Practically all state employes are protected by civil service.

National Forests.—There are in the state of Colorado 15 national forests, with a total

area of 15,158,101 acres, and a land utilization area of 49,920 acres. Of the total area, 13,678,378 acres are under the administration of the United States Forest Service. The following table shows the names of the various forests, the gross area, and the area under the Forest Service of each:

Name of Forest	Gross Area	Area Under Forest Service
Arapahoe	1,057,374	967,644
Cochetopa	1,288,965	1,173,809
Grand Mesa	679,807	653,168
Gunnison	1,363,105	1,283,584
Holy Cross	1,171,841	1,086,352
La Sal	26,674	26,631
Montezuma	837,228	756,440
Pike	1,253,879	1,074,014
Rio Grande	1,400,548	1,289,357
Roosevelt	1,085,143	788,133
Routt	1,114,042	984,098
San Isabel	660,776	617,495
San Juan	1,444,953	1,255,932
Uncompahgre	855,585	786,225
White River	918,181	895,499
Total	15,158,101	13,638,381
Land utilization area	49,920	39,997
Grand total	15,208,021	13,678,378

National Parks and Monuments.—There are two national parks and eight national monuments in Colorado, with a total area of 546,626.48 acres. Rocky Mountain National Park, located in the north central part of the state, embraces an area of 259,416.13 acres. Within its boundaries are 14 massive snow-capped peaks more than 13,000 feet in elevation. The highest of these is Longs Peak, 14,255 feet. Mesa Verda National Park, in southwestern Colorado, has an area of 51,333.62 acres. Within the park is a high-walled mesa rising abruptly 2,000 feet above Montezuma Valley. In the canyons piercing the mesa are the deserted villages of a by-gone race of cliff dwellers. West of Mesa Verda are Yucca House and Hovenweep national monuments, which preserve large ruins of approximately the same period. Black Canyon of the Gunnison National Monument, embracing 13,968.55 acres, is located near Montrose. The canyon is 2,800 feet deep, and is a magnificent spectacle. Colorado National Monument, in western Colorado, embraces an area of 18,310.91 acres, and is a mesa noted for its many odd-shaped and towering monoliths, carved by erosion. Dinosaur National Monument, in northwestern Colorado, and partly in Utah, embraces an area of 155,735 acres. Within this monument area are Tampa and Lodore canyons, ranging in depth from 2,000 to 4,000 feet. The area in Utah contains spectacular beds of prehistoric animals. Grand Sand Dunes National Monument, area 46,034.47 acres, lies in the San Luis Valley, west of the Sangre de Cristo Mountains. Holy Cross National Monument, area 1,392 acres, lies northwest of Leadville. It takes its name from the Mount of the Holy Cross, 13,996 feet high, on which a cross of snow is plainly visible throughout almost the entire year. Wheeler National Monument, area 300 acres, lies near the western edge of the San Luis Valley, and is especially noted for its weird and picturesque rock formations.

Manufacturing.—The principal industries of Colorado are based upon the state's raw materials. They include meat packing, food and kindred products, newspaper publishing and printing, bread and other bakery products, flour and other grain mill products, creamery butter, and petroleum refining. The following table, taken from the reports of the United States Bureau of the Census, gives a comparative summary of manufacturing in Colorado for the years 1935 and 1939:

	1935	1939
No. of establishments	1,175	1,298
Wage earners	23,161	23,716
Wages paid	$ 24,468,831	$ 28,391,933
Cost of materials	$109,421,633	$130,386,505
Value of products	$176,581,246	$221,642,666
Value added by manufacture	$ 66,937,590	$ 91,256,161

Population.—According to the 16th decennial (1940) census, Colorado had a population on 1 April 1940 of 1,123,296, an increase of 87,505, or 8.4 per cent, over the 1930 population of 1,035,791. The census of 1860 was the first in which the area of the present state of Colorado was separately enumerated. The return for this area was 34,277. The population has shown an increase at every census since that time, but the rate of increase has diminished each decade since 1910. The population passed 500,000 between 1890 and 1900, and 1,000,000 between 1920 and 1930. The present population represents a density of 10.8 inhabitants per square mile. Of the 63 counties in the state, 39 gained in population between 1930 and 1940. Summit County, with an increase of 77.7 per cent, had the most extensive growth. The following table shows the total population of the state in 1940 and 1930; also the urban, rural, male and female, white and nonwhite populations:

	1940	1930
The State	1,123,296	1,035,791
Urban	590,756	519,882
Rural	532,540	515,909
Male	571,921	530,752
Female	551,375	505,039
White	1,106,190	1,018,793
Nonwhite	17,106	16,998

Counties.—There are 63 counties in the state, which, with their 1940 populations, are as follows:

Adams	22,481	Lake	6,883
Alamosa	10,484	La Plata	15,494
Arapahoe	32,150	Larimer	35,539
Archuleta	3,806	Las Animas	32,369
Baca	6,207	Lincoln	5,882
Bent	9,653	Logan	18,370
Boulder	37,438	Mesa	33,791
Chaffee	8,109	Mineral	975
Cheyenne	2,964	Moffat	5,086
Clear Creek	3,784	Montezuma	10,463
Conejos	11,648	Montrose	15,418
Costilla	7,533	Morgan	17,214
Crowley	5,398	Otero	23,571
Custer	2,270	Ouray	2,089
Delta	16,470	Park	3,272
Denver*	322,412	Phillips	4,948
Dolores	1,958	Pitkin	1,836
Douglas	3,496	Prowers	12,304
Eagle	5,361	Pueblo	68,870
Elbert	5,460	Rio Blanco	2,943
El Paso	54,025	Rio Grande	12,404
Fremont	19,742	Routt	10,525
Garfield	10,560	Saguache	6,173

* Denver County is coterminous with Denver City.

History.—Colorado (Sp., pp. of verb Colorar, to color; colloquially used for red-colored) was named either from the river of that name or from the varied colors of the landscapes. Its territory is composed of three portions: one from the Louisiana Purchase; one from the Texas Cession; and the third from the Mexican Cession of 1848. The south-

west portion was, in prehistoric times, inhabited by the Pueblos (the Cliff Dwellers). A few of the followers of De Soto and Coronado seem to have entered the territory of the State about 1541. It was explored in the southwest by Escalante in 1776, and its eastern mountain and plain regions by Zebulon Pike (1806) and Stephen H. Long (1820). Later John C. Fremont, led by Kit Carson, penetrated many portions of the Rocky Mountain region. Gold had been discovered in small quantities many times from 1806 to 1857 but the discoveries of 1858, near the confluence of Cherry Creek with the Platte, brought a large number of prospectors into the State. People from Georgia, Kansas, Missouri, and other Eastern States came in large numbers. Prospectors from Kansas and Georgia built Montana on the Platte near where Denver now stands; other towns followed; Auraria, Saint Charles Town (now Denver), Golden, etc.

The discoveries of George A. Jackson at Idaho Springs on the south fork of Clear Creek and by J. H. Gregory on the north fork at Central City brought immigrants by the thousands. At once, local political organizations were made without regard to the territorial government of Kansas, of which Colorado was then a part. It was but a step from making laws for a mining camp to making laws for a whole district, from city building to State building. This step was soon taken. In 1859 delegates met and adopted a constitution for the State of Jefferson with an area somewhat larger than that of Colorado. The opposition to a State led to a second convention which, under the fiction of erecting a territory, established a new State and called it the «Territory of Jefferson.» The constitution adopted by the first convention was ratified but never went into effect. The constitution adopted by the second convention was almost unanimously ratified 24 Oct. 1859, on which day a full complement of State officers was elected. R. W. Steele, who was elected governor, continued in office until 1861, when he surrendered his office to William Gilpin, first governor of the Territory of Colorado.

Colorado was anxious for statehood, but it was not until party necessity compelled the majority party of Congress to turn to the West for more senators, that the enabling act was passed. The Constitutional Convention (in session 20 Dec. 1875 — 14 March 1876) provided that the territorial officers should become the State officers and serve until their successors were elected (at the regular election) and qualified.

Politics.— Colorado was admitted as a Republican State, but has since undergone repeated changes in its political faith.

The following is a complete list of governors:

TERRITORIAL GOVERNORS

William Gilpin	1861–62
John Evans	1862–65
Alexander Cummings	1865–67
A. C. Hunt	1867–69
Edward M. McCook	1869–73
Samuel H. Elbert	1873–74
Edward M. McCook	1874–75
John L. Routt	1875–76

STATE GOVERNORS

John L. Routt	Republican	1876–79
Frederick W. Pitkin	Republican	1879–83
James B. Grant	Democrat	1883–85
Benjamin H. Eaton	Republican	1885–87
Alva Adams	Democrat	1887–89
Job A. Cooper	Republican	1889–91
John L. Routt	Republican	1891–93
Davis H. Waite	Populist and Democrat	1893–95
Albert W. McIntire	Republican	1895–97
Alva Adams	Democrat and Silver Rep.	1897–99
Charles S. Thomas	Dem., Pop. and Silver Rep.	1899–01
James B. Orman	Dem., Pop. and Silver Rep.	1901–03
James H. Peabody	Republican	1903–05
Alva Adams*	Democrat. Served 10 Jan.–16 March	1905
James H. Peabody	Republican. Served one day	1905
Jesse F. McDonald	Republican	1905–07
Henry A. Buchtel	Republican	1907–09
John H. Shafroth	Democrat	1909–11
Elias M. Ammons	Democrat	1913–15
George A. Carlson	Republican	1915–17
Julius C. Gunter	Democrat	1917–19
Oliver H. Shoup	Republican	1919–23
William E. Sweet	Democrat	1923–25
C. J. Morely	Republican	1925–27
William H. Adams	Democrat	1927–33
Edwin C. Johnson	Democrat	1933–37
Teller Ammons	Democrat	1937–39
Ralph L. Carr	Republican	1939–43
John C. Vivian	Republican	1943–47
William L. Knous	Democrat	1947–

* In 1904 Alva Adams and James H. Peabody were candidates for governor. A canvass of the vote gave the certificate of election to Adams and he was inaugurated, 10 Jan. 1905. Peabody filed a contest which was decided in his favor and he became governor 16 March. He resigned 17 March.

COLORADO, Texas, city and seat of Mitchell County, alt. 2,067 feet, 70 miles west of Abilene, on the Texas and Pacific Railroad, the Colorado River, and one federal and three state highways. It is a cotton-growing and stock-raising center. It has cotton compresses, salt and oil wells, and an oil refinery. It has a mayor and council. Pop. (1940) 5,205.

COLORADO, University of, a co-educational institution at Boulder, Colo., incorporated in 1861 by the Territorial Legislature. When Colorado became a State in 1876, the constitution provided that the «University at Boulder» should become the State University, thus giving it the advantage of the lands appropriated by the national Congress for such institutions. The university was opened in 1877, the normal and the preparatory. In 1878 a College of Liberal Arts was established. Later the normal and preparatory departments were discontinued, but other departments were added. These include the colleges of commerce, education, engineering and pharmacy, the schools of medicine

and law, graduate school, training school for nurses, summer session, and university extension. In 1929–30 its teaching staff numbered 371; students, 3,017 (1,092 women); its plant was valued at $7,136,765; its income was $2,229,497; and its library included 221,538 volumes.

COLORADO AGRICULTURAL COLLEGE (Officially Colorado State College of Agriculture and Mechanic Arts), a co-educational institution, founded in 1877, and located at Fort Collins, Colo. It offers courses in agriculture, engineering, forestry, home economics, veterinary medicine, science, vocational teacher training, etc., and maintains a summer school. In 1938–39 it employed a staff of 187 professors, lecturers, assistants, etc.; and in the same year there were 1,892 students enrolled, of whom 498 were women. The institution's grounds, buildings and equipment are valued at $4,688,454.46; it has productive funds totaling $524,706.11, and its income in 1938–39 amounted to $1,404,614.10. The college library contains 90,000 bound volumes. The institution was opened in 1879, and received a grant of 90,000 acres of land under the act of Congress of 1862.

COLORADO CITY, Colo., formerly an independent municipality in El Paso County which sprang up during the gold rush of 1859, but which was consolidated with Colorado Springs (q.v.) in 1916. During 1862 it was for four days the seat of the Territorial Legislature. At the time of its consolidation with Colorado Springs it population was about 1,400.

COLORADO COLLEGE, a co-educational non-sectarian institution in Colorado Springs, organized in 1874. It offers full collegiate courses and confers the degrees of A.B. and A.M. Its grounds and buildings are valued at $2,243,000. The library contains 115,000 volumes and 40,000 pamphlets. The endowment of the college is $2,670,000. In 1939–40 it had 800 students and 70 instructors.

THURSTON J. DAVIES,
President.

COLORADO DESERT. See DESERT.

COLORADO PLATEAU, an extensive plateau region lying west of the southern Rocky Mountains, and east of the southern Pacific Ranges. It includes parts of the States of Utah, Colorado, Arizona and New Mexico. The plateau consists chiefly of Paleozoic and Mesozoic rocks with some Tertiary gravel and lava flows. The rocks are nearly flat lying, but are cut by great north and south faults, of which the best known are the Hurricane and Grand Wash. These faults, together with the Vermilion and other cliffs, divide the plateau into several separate units of differing elevations, varying from 6,000 to 10,000 feet above sea level. These are trenched by the Grand Canyon and its tributaries. The lower parts of the area are desert, the higher parts rather well forested. The plateau has little mineral wealth and is sparsely populated.

COLORADO RIVER, one of the chief streams of Texas. Rising in the high tablelands of Bexar, near the line of New Mexico, about lat. 32° 30′ N. and long. 102° W., it flows southeast, receiving in its upper course the Conca, the San Saba and the Lano on the south, and the Pecan from the north, and empties into Matagorda Bay. Austin, Bastrop and Columbus are on its banks, and Matagorda near its mouth. For most of its course it flows through a fertile region, and has an average width of 250 feet. It is a clear stream; its name, meaning red, was originally applied to the Brazos, north and east, but the two were interchanged. The Colorado is some 900 miles long, and navigable to Austin or farther.

COLORADO RIVER, or **COLORADO OF THE WEST**, a great river of the United States and Mexico, which rises in Grand County, Colo., west of Denver. Flowing generally southwest, it enters the state of Utah about lat. 40° 39′ and at about lat. 38°, long. 110° is joined by the Green River, which rises in the Rocky Mountains in western Wyoming. Until 1921, when first the Colorado legislature and then the Congress changed its name, that part of the Colorado River above its junction with the Green was known as the Grand River. Above the junction with the Green, the Colorado River receives the waters of the Gunnison, the San Miguel, and the Dolores; the Green River, the waters of the Yampa, the White, the Uinta, and the San Rafael. Below the junction with the Green, the Colorado flows southwest through Utah, joined on the east by the San Juan, on the west by the Dirty Devil and Escalante; southwest through the north of Arizona, till its waters are increased by the Colorado Chiquito, or Little Colorado of Arizona. Near the inflow of this tributary is the Marble Canyon, 3,600 feet deep and about one-third the length of the greater canyon below.

From the mouth of the Little Colorado the river bends west and for more than 200 miles flows through the wonderful Grand Canyon. The successive divisions of the canyon are known as the Kaibab section, the Kanab section, the Uinkaret section and the Sheavwitz section. The walls of this water-worn trench are often vertical, or nearly so, for a distance of thousands of feet at a time; sometimes they slope steeply, or constitute magnificent terraces. The cliffs or rock-walls attain a height of from 4,000 to 7,000 feet above the stream. (For heights of particular points, see CANYON). There are frequent whirlpools and waterfalls. Below the canyon the valley opens, and there is much fertile bottom-land on one or both sides of the river. Numerous tributaries pierce the high plateau on either side, the whole presenting a strangely intersected topography. Escaping from the Grand Canyon, the river flows southwest to the borders of Nevada, receiving from the west the Paria, Tapeat, the Kanat (of Arizona) and the Virgin (of Nevada).

Above Callville, Nev., the Colorado, with its tributaries, again bores its way through deep canyons, the sides of which, in some places, present walls of solid rock nearly 7,000 feet high. The plateaus at the top of these rock masses, generally treeless, are again surmounted by terraces 1,000 feet or more high. These lower and higher terraces are both piled with massive ruins, once the walled towns and cities of a race said to be represented by the present Moqui Indians in the northeast of Arizona and the Nahuas of Mexico. Below Callville the river is again shut in by the last of the canyons, the Black Canyon, 25 miles long, and from 1,000 to 1,500 feet high. Shortly after receiving the Virgin, the Colorado takes a southerly course, severing Arizona and Sonora

on the east from Nevada, California and Lower California on the west, and receiving on the east Bill Williams' Fork and the Gila. After absorbing the latter the river sweeps round in a westerly direction for 7 or 8 miles, and soon expands to a width of 1,200 feet. Thence it pursues a tortuous course of 180 miles, the last portion being through Mexican territory, to its mouth in the Gulf of California. There is a vast delta or flood plain formed by the waste from rock erosion. From the sources of the Green River the Colorado measures a total length of about 2,000 miles. It is navigable for steamers as far as Callville, 612 miles from its mouth, and can be made so, it is thought, to the foot of the Grand Canyon, 57 miles higher. The first attempt to navigate the upper part of the Colorado was made in 1891. In 1893 the stream was proved navigable for 130 miles between Green River and Cataract Canyon.

The investigation of geologists dispelled the theory once held that the Grand Canyon was a fracture of the earth's crust. It is now clear that a long period of erosion through plateaus successively uplifted has produced this remarkable gorge. At the bottom of the canyon throughout a considerable part of its course the Archæan system is laid bare. The Algonkian beds with their high coloring give brilliancy to that portion of the canyon where they can be traced. The Cambrian beds are found above the Algonkian, but in places rest directly on the Archæan. The thickness of the Cambrian (here known as the Tonto formation) is in places 1,000 feet. The upper part of the cañon walls consists of carboniferous formations (Red Wall formation below, Aubrey limestone and sandstone above). It has been estimated that all the Eocene, Cretaceous, Jurassic and perhaps Triassic beds and the greater part of the Permian were worn away from the plateau region during the period of erosion. The Marble Canyon platform, like that of the Grand Canyon, consists of carboniferous strata with a considerable number of Permian remnants scattered over it.

In 1540 the Colorado was visited by a detachment of Coronado's expedition and another of his exploring parties gave the first description of the Grand Canyon as seen by white men. About the same time Fernando Alarcon ascended the stream in boats for a long distance. Catholic missionaries subsequently traveled through these regions. For about 300 years, nothing more was learned concerning the Colorado. Much light was thrown on the subject by the investigations of Ives in 1858. In 1869 Powell explored the region and made the descent through the whole course of canyons to the mouth of the Rio Virgen, a distance of more than 1,000 miles. Dutton made geological studies of the Grand Canyon in 1875. In 1889 the canyons were explored by a party of engineers sent out to make surveys.

Boulder Dam, begun in 1930 and completed in 1935, is situated in Black Canyon, about 30 miles S. E. of Las Vegas, Nev. It is 730 feet high and forms a reservoir 115 miles long storing 30,500,000 acre-feet of water.

COLORADO SPRINGS, Colo., city, health resort, El Paso County seat; alt. 5,900 feet, immediately E. of Pike's Peak; 75m. S. of Denver; on the Denver and Rio Grande Western; Chicago, Rock Island and Pacific; Atchison, Topeka and Santa Fe; Colorado and Southern; and Midland Terminal railroads. It has a municipal airport with airline service. The city is the trade center for the Cripple Creek gold field and the shipping point for large quantities of Colorado-mined coal. There are also developed deposits of sandstone, limestone, shale, gypsum, fire clay and building stone. Sugar beets, alfalfa, corn, oats, wheat, lettuce and potatoes are raised in this area. The city was laid out in 1871 by Gen. W. J. Palmer, promoter of the Denver and Rio Grande Railroad, and was first called Fountain Colony because of its location on Fountain Creek. Later it was renamed for the mineral springs near by. It was incorporated in 1872, chartered as a city in 1878, and annexed Colorado City (q.v.) in 1916. Here are Colorado College, Colorado School for the Deaf and Blind, the Union Printers Home, and other cultural and fraternal institutions. The famous Garden of the Gods (q.v.) is between the city and Manitou, and the Will Rogers Shrine is near by on Cheyenne Mountain. Pop. (1940) 36,789.

COLORADO STAGE. The rocks of the Colorado, one of the lower divisions of the upper Cretaceous series, are chiefly of marine origin and cover a great area, having been laid down in an interior sea that stretched from northern New Mexico, where it opened into what was then the Gulf of Mexico, to the Arctic Ocean. This sea at about the latitude of Duluth, Minn., was over 1,000 miles wide. The Colorado is separated into two sub-stages, the lower, or Fort Benton, clays, shales and limestones, and the upper, or Niobrara, shales, sandstones, chalk and chalky marls. The Colorado Stage is of interest because of its marking the time when more of North America was under water than at any other time since the Carboniferous Epoch, and because of the beds of chalk in South Dakota, Kansas, Arkansas, Texas and Mexico. See CHALK; CRETACEOUS SERIES.

COLORATION, Protective. The color of plants and animals is primarily due to the reflection of light, and is dependent in some cases on the pigment in the tissues of flowers, and in the skin, scales, hair or feathers of animals, and in others to structural surfaces which by diffraction give color. Plants are colored green by chlorophyll, so are caterpillars from eating plants. The «chromatic function» is that adaptation of color of the skin of the frog, chameleon, squid, fish or

crustacean, which rapidly changes so as to simulate the tints of the objects on which they rest. In most animals the coloration is due to pigment-cells (see CHROMATOPHORES), which are more or less ramified, and which, under the stimulus of the prevailing color of the habitat, cause the animal to simulate in hue the ground, or tree, or sea-bottom. In most animals the coloration is permanent, in a few it changes with the change of color of the immediate surroundings of the animal, as in the chameleon. In insects, fishes and birds, where the variety of colors is almost endless, it has been found that even the most striking colors are aids to concealment of the identity of the wearer and thus are its protection.

Pigment in Animals.— That this is primarily due to the action of light is proved by the fact that cave animals, or those living in darkness, are white or bleached out, so that the pigment cells become degenerate, the pigment losing its more or less dark color, while in insects the colors are either optical or natural; the pigments, when present, are formed in the cellular layer of the skin (*hypodermis*). These colors tend to fade after death, but when enclosed and preserved in air-tight sacs, such as the scales and hairs of butterflies, and the wing-covers of beetles, they remain bright for a longer time, though eventually fading when dried specimens are exposed to the light. It has been shown that red, yellow, brown and black colors in the scales of certain butterflies are always due to pigments, while in a few cases greens, blues, violets, purples and whites are due to pigments in the scales themselves. Mayer finds that the pigments of the American silkworm moth (*telea polyphemus*) are derived from the blood of the chrysalis. He has artificially produced several kinds of pigments from the blood, which are similar in color to various markings on the wings of the moth, and has found that chemical reagents have the same effects on their manufactured products as on similar pigments in the wings of the living moth.

Origin of Spots, Bands or Stripes.— The markings of caterpillars, the stripes of the zebra, of many African antelopes and of the tiger are supposed by some writers to be due to the direct effects of light and shade, to shadows cast in jungle-grass or in forests. As proofs of this they instance the experiments of Steinach, who glued strips of black paper to the skins of frogs which were kept in the dark; when they were exposed to the light, only the uncovered parts of their skins returned to a lighter hue, while the covered parts remained dark. The reflected green light in the case of frogs turning green when among leaves is by these writers believed to act directly upon the pigment cells. When the bottom of the vessel is covered with felt or with a wire net, the frogs become black, but recover their green color when a green branch is introduced into the vessel containing them. Again those caterpillars living among pine needles are green, striped with white, yellow and red, exactly harmonizing with the red and yellow or white portions of each cluster of needles; this is ascribed to the direct reflection of different shades of light on the moist skin of the caterpillar. In other caterpillars the longitudinal lines are broken up into spots, and if the process is carried on farther the spotting becomes transverse. Eyelike spots on certain caterpillars have been observed to be gradually formed at successive molts from what were originally continuous lines or stripes. It thus appears that the wonderful variety of colors and markings in animals is primarily due to the direct result of the environment, bringing about different results in animals of different groups and exposed to different environments. An alternative theory which has received widespread acceptance is that built up by Abbott H. Thayer upon his observations covering many years, namely, that color in animals is based upon its ability to conceal them in their usual haunts. Obviously this theory works in excellently with the Darwinian theory of Natural Selection. The individuals whose accidental or inherited colorings most effectively concealed them would be those most certain to escape attack and destruction, and survive as parents to reproduce in their progeny the peculiar colors which proved most protective. In this way, it is argued, the coloring of wild animals has eventually come to reflect the colors prevailing in their native environments. The Thayer theory develops upon a basis of the obliteration of relief by the *shading* of the color from darkest on the upper side, which is best lighted from the sky, to lightest on the under side, which is naturally darkened by the shadow. The result is a flat tint conveying no suggestion of solidity. Upon this primary basis, obliteration of outline is accomplished by (1) a color system which is practically a picturing of the salient features of the background against which the animal is most likely to be seen; and (2) a color scheme which, though striking in tone, by its very boldness baffles recognition of the true form. (The theory is set forth in great detail in the book by G. H. Thayer, noted below). (For coloration due to changes of temperature see *Seasonal Dimorphism* under DIMORPHISM).

General Protective Resemblance.— Cases in illustration are the white animals of the Arctic regions, where extreme cold and dryness have turned the hair of the polar bear and the feathers of the snowy owl white. This applies to species; the individual ptarmigan, ermine, hare, fox, etc., turn white in winter, but of a russet hue in summer, due to the differing light reflected from the ground in summer and the snow in winter. The ptarmigan, grouse, prairie chicken and the like, which build open nests, are protectively colored, while the conspicuously marked kingfisher, parrot, etc., build a nest which conceals the sitting bird.

The under side of the wings of certain butterflies, such as the species of *Polygonia, Suvanessa antiopa* and the East Indian *Vallima,* are assimilated in color, together with their often ragged outlines, to dead and tattered leaves; when the butterfly is resting on the ground or in bushes among the dead leaves, it is difficult to distinguish. On the other hand the upper side of the wings are conspicuously marked with reddish hues and conspicuous bars. In the light of the Thayer theory these markings, although conspicuous, became meaningless bits of color in harmony with the environment, and thus afford practical concealment. Certain moths, when resting on the lichen-covered bark of trees, are wonderfully similar

to the surroundings, and are thus protected from the attacks of birds or lizards. In the Arctic regions and in Labrador certain butterflies and moths are of the color of lichen-covered rocks, so much so that when at rest they are difficult to detect.

Special Protective Resemblances.— The most striking examples are the measuring-worms, or geometrid caterpillars, which, when holding themselves out straight and stiff, resemble twigs, not only in shape, but in color and markings; and still more wonderful are those species whose bodies are provided with tubercles which in shape resemble the leaf-bud and other excrescences in the back of the twigs. How to account for the origin of such protuberances is a puzzle. The stick-insect is another example; though not common with us, and supposed to be well protected from the bills of birds, yet in the East Indian Archipelago they are said to be the principal food of one kind of bird. Another example is the famous leaf-insect (*phyllium*) of Java, in which the wings are very broad, thin and marked with veins like the mid-rib and side-ribs of a leaf. Such instances as these are cited as buttresses to the Thayer theory of concealment.

Recognition Marks.— By Waller and others the stripes of the African antelopes, the upturned white tail of the rabbit and hare, and the bars and other conspicuous markings of birds that fly in flocks, are regarded by some as recognition marks, but others consider that this is rather fanciful and that they are protective alone.

Warning Colors.— Certain animals, of which the skunk affords an example, are so marked as to be easily distinguished by their enemies, which, knowing by experience their offensive nature, pass them by. Hence the conspicuous stripes of the different species of these animals in the New World. There are many cases of brightly colored caterpillars which are avoided by birds and lizards which greedily devour green ones. The conspicuous red, blue and purple spots and stripes are advertisement of their inedibility. In Nicaragua, Belt observed that while ducks and fowl fed on ordinary green frogs, a small species gorgeously colored with red and blue was avoided. On offering one to ducks and fowl they all refused to eat it, except one young duck, which took the frog in its mouth, only to drop it, going about jerking its head as if the taste of the frog was nauseous. Although these striking markings are supposed to be the result of natural selection, Eisig's theory that the abundant secretion of pigment is the cause of the distastefulness seems better grounded. Indeed a large number of cases of protective mimicry seem due to the direct action of light and warmth in bringing about the varied hues of the pigment — moreover the range of primary colors is not very great, and the hues are apparently due to the action of the environment, so that we need not, in most cases at least, invoke the somewhat fanciful hypothesis of Wallace, Poulton and others to account for these resemblances. As Eisig claims, the abundant secretion of pigment has caused the insects to be inedible, rather than that the bad taste has caused the production of bright colors as an advertisement or warning signal.

Insects Attracted Rather by the Odors of Flowers than Their Colors.— It has been argued by Lubbock and others that the colors of flowers attract insects, and that the gay lines and stripes leading down to the bottom of deep corollas are guides to the nectar. At present this view has been stoutly opposed by Plateau, after many observations, who thinks that the color of flowers has no connection with the visits of insects, but that they are attracted by the odor of the nectar. He finds that any flower is freely visited if it be nectariferous, no matter how colorless or inconspicuous it may be. Many gay flowers are wholly avoided by insects, but on placing nectar at the base of such flowers insects were at once attracted. It appears from Plateau's observations that color is not a primary factor in attracting insects to flowers. Though bright blossoms are undoubtedly seen by insects from a distance, when they once reach the flowers it is a matter of indifference to them what their color is — blue, red, yellow, green or white — if they differ from one another in no other respect. Consult Beddard, F. E., 'Animal Coloration' (New York 1895); Newbigin, M. I., 'Color in Nature' (London 1898); Poulton, E. B., 'The Colors of Animals' (New York 1890); Thayer, G. H., 'Concealing Coloration in the Animal Kingdom' (New York 1909); Wallace, A. R., 'Natural Selection and Tropical Nature' (New York 1895); also works by Lubbock, Plateau, Coste, Urech, Eimer, Hopkins, Weismann, Tenneck.

COLORIMETER, an instrument for measuring the depth of color in a liquid by comparison with a standard liquid. They are of three general types, based upon the three variables in the intensity of colored solutions: (1) the quantity of coloring matter required to make the match; (2) the volume of the solvent in which it is held; (3) the thickness of the solution through which the light passes before it reaches the observer's eye. These principles are applied (1) when two solutions are brought to agreement in color by the addition of coloring matter; (2) when the match is effected by dilution of one of the two solutions; (3) when the solutions are made to match by changing the thickness through which the light beyond is forced to pass. The form most commonly in use is of the second type. It consists of two long, narrow glass tubes placed side by side on a stand. The standard liquid and the one in question are poured, in equal quantities, one into each tube; and water is then added to the darker till its tint becomes the same as the other. The amount of water used is a measure of the depth of color in the given liquid. The White colorimeter is the principal exponent of the third class. It consists of two hollow wedges of glass placed side by side, and arranged so that one may slide up and down on a bar upon which is marked a scale. The solution to be measured is placed in one of the wedges and the standard solution in the other. Both are viewed through a horizontal slit. The wedge containing the standard is raised or lowered until the color is matched, and the scale is read.

Another type of colorimeter is employed to measure or test the colored light reflected from opaque bodies. The Ives colorimeter is of this type. It consists of a hollow box about 3

by 4 inches and 20 inches long, with a viewing lens at one end, a diffraction grating, and at the farther end lenses and slits which can be adjusted. The field of view is divided by means of a diaphragm so that the light to be tested appears in the upper half while the lower half is lighted by a mixture of red, green and blue-violet rays from the grating. The slits through which the color rays come are opened or closed as the case may require, and the analysis is read on the three color scales. A new (1912) precision colorimeter constructed for the United States Bureau of Standards measures the wave length of the color which is to be tested. The instrument is so arranged that colored rays taken from a spectrum are mixed with white light to match the unknown hue; or, in the case of purples, the rays from the spectrum are mixed with the unknown to make white light. The instrument is operated through the use of a Lummer-Brodhun photometer cube.

COLORING, one of the essential parts of painting — namely, that part which relates to colors. Besides a knowledge of the art of preparing and mixing colors, and the whole mechanical process from the beginning to the finishing of a picture, which in the various kinds of painting varies according to the materials of each, coloring comprehends the knowledge of the laws of light and colors, and all the rules deducible from the observation of their effects in nature, for the use of the artist. This subject has been treated by Leonardo da Vinci in his work on painting; Lomazzo and Gérard Lairesse in books on the same subject; Mengs in his 'Praktischer Unterricht'; Goethe in his 'Farbenlehre'; etc. The skill of the painter presupposes a natural ability founded on superior sensibility — namely, the ability to image forth, and to express with characteristic truth, the peculiar substance and color of any object under the influences of the light and air. With the limited range of pigment colors at his disposal, bounded at one end by the dead white of a piece of white paper, many degrees darker than a sunlit cloud, and at the other end by a flat black many degrees lighter than a piece of black velvet, the artist's work becomes practically a translation from nature, instead of an imitation. For if the colors of nature were reproduced faithfully, her effects would be lost through the limited scale of expression available. The skill of the artist is exhibited in so adapting his translations of local colorings that the effects of nature are virtually reproduced in colors so correct relatively to the other colors of the painting that they are recognized as eminently truthful. To make this translation successful, accurate attention to the relative values of the local tones and tints is requisite. By local tones we understand the natural color of an object as it appears on the spot where it stands, or from the spot where the spectator is supposed to be stationed. In works of art the natural color of an object appears always as a local tone, because every object must be regarded from only one point of view, conformably to which the natural color is modified according to the supposed distance. By tints we understand, in a more restricted sense, the gradations of the clear and obscure which lights and shadows produce on the colored surface. In no object of art do these modifications and shades exist in greater delicacy and diversity than in the human face, which is consequently the most difficult subject for a painter. Coloring, in as far as it is an imitation of the color and character of flesh (the naked body), is called carnation (q.v.). If, in addition to the skilful translation of the natural colors, local tones and tints of its original, the artist also expresses in his work the peculiar character of the substance of which the object consists, the coloring is called true. But to truth should be joined beauty, which is attained by the harmonious union of all the tones of the painting into one dominant tone. The coloring must conform to and promote the object of the painting as a work of art, and by the harmony of the colors and lights; as well as by the truth of the local colors, and of the individual parts of the subject, constitute one beautiful whole. In the choice of lights and the distribution of colors the artist should aim not only at clearness of representation, but at the same time at the production of a pleasing harmony, which should aid the general impression of the work. Consequently harmony and chiaroscuro are comprised in the idea of correct, beautiful coloring. We often see pictures in which the colors are true to nature but which have little merit and are deficient in a harmonious union of excellences.

COLORING MATTERS. This name ought to include every substance, organic or inorganic, which is the cause of color in another, but in practice it is restricted to the natural coloring matters of vegetables and animals, and to the dyes that are used for coloring fabrics. The reason of this restriction probably is that these coloring matters are distinctly different from the tissues or fluids which contain them, whereas the color of a mineral is not in general due to a separable body, but is peculiar to the mineral itself. It is impossible, for instance, to take away the blue color of a copper compound, or the green or yellow of one of chromium. In the mineral world the analogy to the coloring of plants is found rather in rocks; for example, in a sandstone colored with oxide of iron, where the coloring matter may be removed without the rock mass being destroyed.

The organic coloring matters derived from vegetables are both important from their uses in the arts and interesting from their character and decompositions. They may be divided into two classes, those which exist ready formed in the plant, and those which are obtained by the spontaneous or artificial decomposition of some principle in the plant. Of those belonging to the first class, chlorophyll, the green coloring matter of leaves, and the different colors in flowers, are the most obvious. Those however, which are used in the arts are not at first sight apparent, being contained in the seed, bark, stem or roots, from which they can be extracted by water, alcohol, ether, dilute alkalis, etc. The second class includes bodies which result by oxidation or other chemical change from some usually colorless matters, to which the name «chromogens,» color-producers, has been given; and, indeed, the question has been raised whether all coloring matters, even in plants, have not been produced from prior chromogens. Although coloring matters have been subjected to numberless investigation by chemists, very little is known about their real constitution. Coloring matters are generally odorless, with a

rough taste, soluble, some in water, others in alcohol. Indigo and alizarine can be sublimed but most are decomposed by a comparatively slight elevation of temperature. They all consist of carbon, hydrogen and oxygen, to which in some cases nitrogen is added. Some exhibit a weak acid tendency, combining with the oxides of lead, copper and especially tin, iron and aluminum, and forming insoluble colored compounds called "lakes." Some have the power of attaching themselves permanently to different vegetable and animal fibres, as silk, wool, cotton and linen; others are unable to give a color which will not redissolve in water; in such cases the fibre is mordanted, that is, treated with one of the metallic oxides just mentioned, and then, when immersed in the color, the insoluble lake is precipitated in the fibre. Many coloring matters are liable to change by exposure to daylight; they are also affected by a number of chemical reagents—certain blues, for example, are turned green by alkalis, and red by acids; they are destroyed by nitric acid, bleached by chlorine, decolorized, but not always permanently destroyed, by sulphurous acid, sulphuretted hydrogen, etc.

Of the vegetable coloring matters the yellows are the most abundant, and different shades are obtained from different plants: fustic, turmeric, quercitron, Persian berries, morindin, saffron, arnotto, purree, chrysophanic acid and others; of the blues, indigo and litmus are the most familiar; and of the reds and purples, madder, logwood, Brazil-wood, safflower and a few more. Most of these colors require complicated operations to separate them in the pure state.

The only green coloring matter known, of no importance as a dye, but indispensable to the life of the plant, is chlorophyll. It was formerly supposed to be a simple substance. It was obtained from an alcoholic extract of leaves by adding lime, then decomposing the lime-chlorophyll compound with an acid, and agitating with ether, from which the chlorophyll was got by evaporation. But by another process it was found that it could be separated into two bodies, one yellow, the other blue; and by the application of the spectroscope, Stokes showed that chlorophyll contains four coloring matters, two yellow and two green, differing in optical properties. By further study in the same direction Mr. Sorby thinks he has proved that besides the greens there are four or five distinct yellow coloring matters, to which he has given special names. It is quite obvious, if this be so, that our knowledge of the nature of chlorophyll is just beginning, for each coloring matter will become an object of chemical and physiological investigation, and not till then will it be possible to say how chlorophyll is produced and acts in a plant. Experiments have been recently made to elucidate precisely the fading of chlorophyll when exposed to light, a change which is accompanied by altered spectrum bands, but in their present state they are too inconclusive to be detailed here.

The chief animal coloring matters are those of the blood, the bile, the urine, the retina, of the muscle and of the skin. The blood's coloring matter is the well-known hemoglobin, while the pigments of the bile, bilimbim and its oxidation product, biliverdin, are derived from the blood pigments. Biliprasin and fuscin, bilicyanin, bilipurpurin and bilixanthin, are other bile pigments. They may be regarded as various products of oxidation and reduction of the initial bile pigments. Urochrome is the general name applied to the urinary pigments. Its exact composition is by no means definitely understood. In the retina there are a number of pigments or chromophenes. They are mostly lipochromes, or fatty pigments, and have been named rhodophane, chlorophane and xanthophane, these being red, green and yellow respectively. There is a further black pigment in the eye, fuscin, allied to the melanins of the skin and hair. The muscle pigments are identical with the blood pigments. The skin pigments belong to a group known as the melanins. It is undecided whether these are iron pigments or not.

The artificial coloring matters may be divided into two classes, those which exist ready formed in nature, as many of the common red and brown earths, or which are formed by the mechanical mixture of such naturally existing colors, and those which do not exist in nature, but are produced by chemical operations. The latter are of mineral or of organic origin, examples of the first class being afforded by Scheele's, Guignet's and other greens, artificial ultramarine, smalt and many others, and of the latter by Prussian blue and especially by the aniline colors. The artificial colors are more particularly described in the articles COAL-TAR COLORS; DYES; PIGMENTS.

COLORS, in the army, the flags carried by each dismounted regiment. The corresponding flags of mounted units are called standards. They differ from colors in size alone. Each British infantry battalion (formerly regiment) except rifles carries two colors, the royal or first color, and the regimental or second color; neither of these is now carried into battle. They are carried by subalterns and formerly were guarded by the respective chief non-commissioned officers of the companies, the color-sergeants. At present there are no color-sergeants. Each United States regiment or separate battalion carries the national and the regimental color or standard, the latter of the corps color, bearing the regiment's number; they are carried by non-commissioned officers, the color-sergeants, and guarded by two privates. In the navy the term colors is applied only to the national flag.

COLORS. See COAL-TAR COLORS.

COLORS IN ART AND SYMBOLISM. When a connoisseur examines an Oriental rug he takes into consideration the symbolic intent of the color scheme as well as of the motifs depicted. He remembers that, to the Mohammedan, green is a sacred color and must not be trodden on. Collectors of Chinese ceramics in examining examples claimed to belong to a certain reign in the Ch'ing Dynasty have to bear in mind that yellow was for some time in that Dynasty an Imperial color and its use strictly forbidden except for the Imperial court. Hence any other than the finest art work appearing on such a piece of porcelain containing yellow in its decorative composition proves it to have belonged to some other period. But while symbolism generally originated in the East its antiquity in and among the European peoples dates very far back. And the arts, both profane and ecclesiastical, have

used colors with symbolical intent almost universally.

White.— As symbol of innocence and purity white has been adopted over a large portion of the globe even during prehistoric days. In pagan times we find it as symbol also of light, and the Druids in white robes sacrificed white oxen to the sun; the head of Osiris of the Egyptians wore a white tiara. The Romans dedicated white to Jupiter (god of light), and on the first day of January the consul, robed in white and mounted on a white horse, rode up to the Capitol to celebrate the triumph of Jupiter over the spirits of evil; the priests of Jupiter wore white vestments and the victims sacrificed to that god were white. The Greek priests sang sacred chants in white robes. In antiquity white was dedicated to the dead and was sign of mourning, and this remains so to this day with the Persians, Chinese and Indian Mohammedans. In old biblical lore white vestments were symbolical of the soul's regeneration and a recompense of the elected. Early Christian artists depicted God the Father draped in white and Jesus was pictured in white robes after the Resurrection. The dead were swathed in white and Pythagoras called the practice a happy presage of immortality. Aaron, the Jewish high priest, was commanded to wear a white garb in the sanctuary. In Christian art, white being considered emblem of innocence and purity, lilies are found in pictures of the Immaculate Conception; it was for the same reason that some monks and nuns of the Christian Church wore white robes. The Magi were robed in white. In Christian iconography white is represented by the diamond or by silver as emblems of light, innocence, virginity, faith, joy and love. But white roses opposed to red ones signified death, rest, killing of inordinate desires.

Black.— In pagan antiquity black represented the underworld. Black, as "the negation of colors" is symbolic of death, darkness and evil, also of falsehood and error, sorrow and vice. The illuminators of the Middle Ages represented Christ draped in black while wrestling with the Spirit of Evil, and in the 12th century, in Byzantine art, the Virgin Mary often has a black complexion symbolic of woe. Black for mourning and mortuary color is a very ancient tradition. Georgius writes: "Black is the third of the four sacred or canonical colors, and is used by the Roman Church (and formerly by the Eastern Church too) on penitential days." Black has also been considered as signifying counsel and antiquity, but in heraldry it is symbolic of prudence, wisdom and constancy in adversity and love. White and black in combination signify in Christian art purity of life and mourning or humiliation, as adopted by the Dominican and Carmelite orders. Black and yellow in combination were symbolical of the devil and his hosts. To the Moors black designates grief, obscurity and constancy.

Violet.— The Roman Catholic Church considered violet and black so closely allied as to use them indiscriminately for one another on days of mourning and fasting. Violet clothing was worn by cardinals and old women and was an acknowledgment of old age.

Purple.— To the Tyrians (whence came the purple dye) and Romans a purple robe or band of purple signified authority; it became the Roman symbol of majesty, and its use was allowed only for royalty and for persons in high office or for priests.

Blue.— Eusebius tells us blue was the color of the clothing of the gods, especially of Juno (Queen of the Heavens). In Christian art light blue (sky-blue) was symbol of divine eternity and human mortality, hence was used as a mortuary color. The coffins of the young were covered with blue cloth and the mortuary cloth was of this color; a red and a blue pall, one over the other, signified divine love, raising the soul to immortality. The baldachin, as emblem of heaven ("canopy of heaven") was blue beneath, and church *ceilings* (from the Latin *cælum*, "heaven") were generally painted blue and powdered with gold stars. Blue signifies likewise piety and sincerity, also contemplation. The Jewish high priests wore it about their garments as significant of divine contemplation, and the church copes and chasubles were frequently of this color, though it is no longer a vestment color. As an angel's garment in art blue is symbolic of faith and fidelity. In tradition and art the Virgin Mary wore a mantle of blue, in which case it symbolized modesty. This color when worn at the celebration of the Mass signifies humanity and expiation. In heraldry blue (*azure*) is symbol of chastity, loyalty, fidelity, good reputation. Blue to the Persian signifies air, to the Mongolian authority and power.

Red.— In symbolism red signifies life, love, passion, fire, heat. It is the color of blood and hence represented anger, war and incendiarism. Red lions, foxes, squirrels were sun and fire symbols. In Christian art red represents opposite attributes; it is sign of burning zeal for the faith, of energy and courage, also of cruelty and guilt of bloodshed. The Israelites stained their door posts with red as a sign that the Avenging Angel should allow life to its dwellers. Red is the prominent color in Passion Week and on Good Friday. Rose-color signifies divine wisdom with the Buddhist and Mohammedan. In modern times red is symbol of revolution and anarchy. Red flowers are love signs.

Yellow.— This color very generally signifies envy, hate, quarrelsomeness. In Christian art yellow was symbol of the sun, also of the goodness of God, of marriage and initiation, faith and fruitfulness. In Christian iconography we find the illuminators and miniature artists of the Middle Ages depicted Saint Peter in a yellow robe as faithful guardian of the Church. Yellow has been symbol of treason, hence in France the doors of traitors were daubed with yellow and Judas is often found clothed in yellow in pictures. In some countries the Jews, for betrayal of the Lord, were enforced to wear yellow clothing. In Spain the executioner wears yellow or red, the former indicating treason of the victim and red its punishment. In heraldry yellow is symbol of love, constancy and wisdom, or in opposition, inconstancy, jealousy and adultery. The Japanese consider golden yellow symbol of the sun, riches, joy, etc., hence their chrysanthemum fête. Yellow was a Chinese symbol of royalty, also of high office under royalty, hence the gift of the "yellow jacket" as insignia showing high regard of the Imperial court.

Green.— To the ancient Egyptians this color was symbol of hope, growth, joy of spring. In the Middle Ages green became symbol of unripeness, as green youth, also of poison, hence dragons and snakes were painted green. Green was supposed to be good for the eyes, and Theophrastus wrote that emeralds were mounted in rings for persons with bad sight to be looked at by them. To the Mohammedan green is a sacred color and symbol of immortality. In modern times green has come to signify envy.

Brown.— With the ancient Egyptians brown was dedicated to Typhon and in olden times was generally a sign of mourning. Compounded of red and black, this color has been also symbol of treason and evil deeds. In monastic robes it signified renunciation. The Moors considered it emblem of evil, and in Christian art, brown, the color of the dead leaf, symbolized spiritual death.

Gold.— In Christian art, when used as a background, gold meant majesty of the subject depicted; it was also used for the nimbi of saints as "glory." Gold signifies purity, dignity, wisdom and glory.

Orange.— With the Buddhists and Mohammedans orange is the color symbolizing sorrow.

COLOSSÆ, kō-lŏs'ē, an ancient city in Phrygia, situated on the Lycus, a branch of the Mæander. Colossæ had disappeared by the Middle Ages, and it is uncertain whether it was superseded by the town of Chonæ in its neighborhood, or whether Chonæ was Colossæ with only a change of name. It was first mentioned by Herodotus, Xerxes passed through it on his march to Sardis, 481 B.C., and it was a place of considerable mercantile importance in the time of Strabo. One of Paul's epistles was addressed to the Colossians, from which it is known that Colossæ was the site of one of the early Christian churches. Consult Ramsay, 'Cities and Bishoprics of Phrygia' (Vol. I, 1895).

COLOSSAL CAVERN, The. A large cave discovered in 1895, the entrance to which is about one and a half miles distant from the entrance to the Mammoth Cave, of Kentucky. On account of its immense size and the varied character of its formations, the Colossal Cavern is a most worthy rival of the Mammoth Cave. The Louisville and Nashville Railroad Company purchased the Cavern in 1896; acquired the land under which its course was found to run, and widened narrow passageways, smoothed rough places, built stairways and did many other things to make exploration easy. There are four separate entrances to the Cavern, only one of which (an artificial entrance) is used by visitors. Among the attractions of the Cavern are Colossal Dome, 135 feet high, which is the most symmetrical as well as one of the largest domes known; Vaughn's Dome, 78 feet in height, which is approached through a magnificent canyon, about 300 feet in length; the Twin Pits, 65 feet deep; the Lover's Gallery, 400 feet long; the Ruins of Carthage, 400 feet long and 100 feet wide; Pearly Pool; Pulpit Rock, and Dining Room.

COLOSSEUM. See COLISEUM.

COLOSSIANS, Epistle to the. An epistle of the Apostle Paul addressed to the "Saints and faithful brethren who are at Colossæ." Colossæ, though 100 miles east of Ephesus and less important than the adjacent Laodicea (Col. ii, 1) and Hierapolis (iv, 13) in the Lycus Valley, yet lying like them on the great trunk road which joined the Ægean with Syria, was in living communication with "all the [Roman] world" (Col. i, 6). Paul the apostle may have passed that way from "the upper country" to Ephesus (Acts xix, 1) but none of his future disciples saw his face in that region (Col. ii, 1). It was rather through his two years daily reasoning in the school of Tyrannus that "all they that dwelt in Asia heard the word of the Lord, both Jews and Greeks" (Acts xix, 9f). Epaphras, finding his way from Colossæ (Col. iv, 12) to the provincial capital, became Paul's "fellow-servant and faithful minister of Christ on his behalf" to the towns on the Lycus (Col. i, 5–7; iv, 12f) and the founder of the churches in Colossæ, Laodicea, and Hierapolis. Two other Colossians, Philemon and Archippus, are named fellow-workers and the latter is exhorted to fulfil his "ministry received from the Lord" (Philem. 1; Col. iv, 17). Two house-churches are mentioned, one in the house of Apphia at Colossæ (Philem. 2) and another in that of Nymphas in Laodicea (Col. iv, 15). The membership of the churches included slaves and their well-to-do owners (Col. iii, 22ff iv, 1; iii, 11; Philem. 15f).

The content of Paul's gospel to this Gentile population (Col. i, 27) may be divined from his contemporary first Corinthian epistle, in which his characteristic stress is laid upon the transcendent and cosmic rank of Christ, as sole divine agent in all creation (1 Cor. viii, 6) and upon his unique redemptive function through his incarnation, death and resurrection (1 Cor. xv, 1–4; i, 23–24, 30; vi, 11). The apostle's foreboding that after his departure from Asia some of his own converts would "speak perverse things to draw away the disciples after them" (Acts xx, 30) was to be realized in Colossæ. His failure to visit the valley churches, a natural local jealousy toward Epaphras and scant regard for his teaching ability, gave an ambitious leader (note singular number in ii, 4, 8, 16, 18) an opportunity to promulgate an alleged higher type of doctrine, with syncretistic elements of ultimate Jewish (ii, 14, 11, 16), and perhaps Grecian (ii, 8, 23; i, 26; ii, 3), Phrygian (ii, 12) and Oriental (i, 16) origin. The new teaching, harmonizing with the inherited prepossessions of Gentiles but newly won to the Christian faith, and addressed not to the common herd but to persons flattered as possessed of superior intelligence, made a headway which Paul's unlearned sponsors found themselves powerless to arrest. They felt that no less potent a reasoner than he of the school of Tyrannus, now unfortunately a prisoner in distant Rome, could cope with the subtle and sinister propaganda. Epaphras, therefore, takes the bold venture of an arduous and perchance futile journey all the way to the imperial capital. He finds the apostle still among

the living and prepared to meet the dire emergency in the valley churches. Tychicus, possibly an abler representative than Epaphras, is armed with oral instructions and dispatched with a circular letter (our so-called "Ephesians") to "the churches of Asia" (1 Cor. xvi, 9), a second letter to the Colossian church dealing with the heresy, and a personal letter to Philemon, together with a "living epistle" (2 Cor. iii, 2) in the person of the latter's converted runaway slave, Onesimus (Col. iv, 7–9; Eph. vi, 21; Philem. 10–16).

Paul's method in refuting the false teaching at Colossæ is to renew his earlier emphasis upon the transcendence and immanence of the crucified and risen Christ Jesus (Col. i, 15–17) as taught in the school of Tyrannus (1 Cor. xv, 1–4; viii, 6; iii, 23). He whom they have "received as Lord" (Col. ii, 6) is One "who is before all things," "through whom and unto whom all things have been created," and "in whom all things consist" (i, 16–17), who therefore is "all, and in all" (iii, 11) and "in them, the hope of glory" (i, 27). After the opening salutation, thanksgiving for their Christian graces of faith, love and hope, and prayer for their deeper spiritual knowledge and for life worthier the indwelling Christ, he sets forth in the *doctrinal section* (i, 13–ii, 3) the pre-eminence of Christ as Redeemer from sin, unique revealer of God, creative agent and sustainer of the universe, including every rank of intermediate beings (i, 13–17); and as crucified and risen Head of the Church, the sole divine mediator for restoring harmony in heaven and earth, through the Gospel divinely entrusted to Paul for them and all Gentiles of every class and condition (i, 18–ii, 3). The polemical section following (ii, 4–iii, 4) contrasts the sufficiency of Christ's gospel with the insufficiency of the false teaching. Cleaving to Christ and his gospel, they are to accept no false human philosophy as a substitute (ii, 4–8); for in him dwells the whole living omnipotent Deity, as in no lesser being, to meet every human need (ii, 9–10); to raise them with himself from the corruption and death of sin to the life of obedience, to put an end to the servitude of the Mosaic law and of the powers of evil (ii, 11–16). The new ceremonialism is shadow: but Christ is substance; its worship of angels a fiction of the imagination, replacing personal and vitalizing union with Christ, the living Head; its ascetic rules a pitiful substitute for ethical death and victorious life with Christ over the power of the flesh (ii, 20–iii, 4). The *hortatory application* follows: Put off the old nature: put on Christ! (iii, 5–iv, 6). United to Christ they are to reproduce His own death to the world and its vices (iii, 5–11), His life of love and joyous service to God and man (iii, 12–17); in their homes they are to incarnate His spirit (iii, 18–iv, 1) and live His life of prayer for the extension of His gospel (iv, 2–6). The *personal conclusion* (iv, 7–18) contains a reference to Tychicus and Onesimus, salutations, instructions as to exchange of epistles with the Laodiceans and the autograph signature.

Bibliography.— Critical discussions of the problems of authorship, vocabulary, style, relation to Ephesians and the Colossian heresy may be found in the New Testament 'Introductions' of Zahn (Eng. tr., 1909); J. Moffatt (1911), B. Weiss (1897), H. J. Holtzmann (1892), Jülicher (Eng. tr., 1904); W. Sanday's article in Smith's 'Bible Dictionary' (2d ed., 1893) and detailed exegesis in the commentaries of J. B. Lightfoot (1875), H. von Soden (1893), A. S. Peake (1903), Haupt (Meyer 1897).

MARCUS D. BUELL,
Professor and Dean Emeritus School of Theology, Boston University, Author, "Autographs of St. Paul."

COLOSSUS, kō-lŏs'ŭs, in sculpture, a statue of enormous magnitude, from which our adjective colossal is derived. The people of the East from the most ancient times have been celebrated for colossal sculpture. The pagodas of China and of India and the excavated caverns of the East abound with colossi of every description. The Asiatics, the Egyptians, and in particular, the Greeks, have excelled in these works. The celebrated colossus of Rhodes was reckoned one of the seven wonders of the world. It was raised by the Rhodians in honor of Apollo. Strabo, Pliny and other ancient authors who lived at the time that the colossus of Rhodes is said to have been in existence have given its height as 70 cubits, or about 105 feet. Other authors who flourished since its destruction report its height at 80 cubits. The statue stood at the entrance of the harbor of Rhodes, but there is no authority for the statement that it bestrode the harbor mouth and that the Rhodian vessels could pass under its legs. Of other colossal statues of ancient times the most celebrated are the Olympian Zeus and the Athena of the Parthenon, both the work of Phidias. The virgin goddess was represented in a noble attitude, 26 cubits or 39 feet in height, erect, clothed in a tunic reaching to the feet. In her hand she brandished a spear, and at her feet lay her buckler and a dragon of admirable execution, supposed to represent Erichthonius. The statue of Zeus was 60 feet high. The earliest colossus recorded to have been sculptured in Rome was the statue of Jupiter Capitolinus, which Spurius Carvilius placed in the capitol after his victory over the Samnites.

Among modern works of this nature are the colossus of San Carlo Borromeo at Arona in the Milanese territory; the four colossal statues at Paris in front of the façade of the palace of the Chamber of Deputies, representing four of the greatest French legislators; and a statue of Germania, 34 feet high, on a pedestal over 81 feet high, erected near Rüdesheim in commemoration of the unification of the German Empire. In the United States a figure of "Liberty Enlightening the World," 151 feet high on a pedestal 155 feet high, has been erected in New York, overlooking the harbor and serving as a beacon. It was the work of the French sculptor Bartholdi, and was constructed mainly through the efforts of a French-American Union formed in 1874. In 1880 it was presented by France to the United States, and six years later it was placed on its present site, Bedloe's Island.

The statue of Charles IV of Spain at the head of the Paseo de la Reforma in the City of Mexico is the largest equestrian statue on the American continent and the second largest in the world.

COLOSTRUM, the name given to the first milk yielded after the birth of the young. It differs from ordinary milk in appearance and composition. It contains a larger percentage of ash and total solids than ordinary milk and a greater proportion of albumin to casein, but less sugar of milk. There are also minute fat granules known as colostrum bodies and which are believed to be the débris of the cells of the mammary gland. Colostrum has a purgative effect upon the new-born infant and removes the meconium from the fœtal intestine. Colostrum gradually assumes the characteristics of normal milk within a few days after parturition.

COLQUHOUN, ko-hoon', **Archibald Ross,** British colonial administrator, explorer and author: b. off Cape of Good Hope, March 1848; d. 18 Dec. 1915. He entered the Indian Public Works Department in 1871, and was a member of the mission to Siam in 1879. In 1881–82 he explored the proposed railway route between Burmah and China, and was deputy-commissioner of Upper Burmah 1885–89. He was administrator of Mashonaland 1900–02. In 1895 he visited America to explore the Nicaragua and Panama Canal routes. He had traveled extensively and was the author of numerous works, including 'Among the Shans' (1885); 'The Key of the Pacific' (1895); 'China in Transition' (1898); 'The Mastery of the Pacific' (1902); 'Germany and Sea Power' (1909).

COLQUHOUN, John, Scottish writer on sport: b. Edinburgh 1805; d. 1885. He was educated at the university of his native city. In 1840 he published 'The Moor and the Loch,' an extremely diverting account of his adventures as a sportsman. The volume was immensely popular and an autobiographical preface was added to the fourth edition (1878). Other works by him are 'Rocks and Rivers' (1849); 'Salmon Casts and Stray Shots' (1858); 'Sporting Days' (1866).

COLQUHOUN, Patrick, English magistrate and advocate of police reform: b. Dumbarton 1745; d. 1820. He went to Virginia at an early age and there became a successful merchant. In 1766 he returned to Glasgow, became prominent in the public affairs of that city, founded the Glasgow Chamber of Commerce in 1782, the oldest institution of the kind in Great Britain. In 1789 he removed to London, where in 1795 he issued his 'Treatise on the Police of the Metropolis,' in which he advocated a complete reform of the London police system. Many of his recommendations were adopted subsequently by the authorities. In 1798, having come into notice through the inauguration of important municipal reforms, he was appointed magistrate at Westminster. Other works by him are 'System of Education for the Laboring People' (1806); 'On Indigence' (1806); 'On the Population, Wealth, Power and Resources of the British Empire' (1814, 2d ed., 1815).

COLQUITT, Alfred Holt, son of Walter T. Colquitt (q.v.), American legislator: b. Walton County, Ga., 20 April 1824; d. Washington, D. C., 26 March 1894. He was graduated at the College of New Jersey in 1844 and settled in his native State as a lawyer. He served in the Mexican War, and was elected to Congress in 1852 as a Democrat. Upon the outbreak of the Civil War he entered the Confederate army as a captain and rose rapidly to the rank of major-general. He was governor of Georgia in 1876–82 and United States senator in 1882 and in 1888.

COLQUITT, Walter T., American lawyer: b. Halifax County, Va., 27 Dec. 1799; d. Macon, Ga., 7 May 1855. He was educated at Princeton; was admitted to the bar in 1820; became a district judge in 1826, holding the first court ever held in Columbus, Ga. He was a successful lawyer, and in criminal practice was without a rival in his State. He was a member of the Georgia State senate 1834, 1837; a representative in Congress 1839–42; a United States senator 1843–55, and a member of the Nashville Convention 1850.

COLT, LeBaron Bradford, American jurist: b. Dedham, Mass., 25 June 1846; d. Bristol, R. I., 18 Aug. 1924. Graduated at Yale in 1868 and two years later from the Columbia Law School. He practised law in Chicago and Providence, R. I., and from 1879 to 1881 was a member of the Rhode Island House of Representatives. In 1881 he became United States district judge for Rhode Island, and from 1884–1913 was United States circuit judge for the first judicial circuit. He was elected to the United States Senate in 1913; re-elected 1919.

COLT, Samuel, American inventor: b. Hartford, Conn., 19 July 1814; d. there, 10 Jan. 1862. He had a common school education and was employed in his father's textile mill, but went to sea as a sailor when 15. His attention being drawn to firearms while at sea, he began to perfect a revolver and patented it in 1835. Its great success led to the erection by him at Hartford of one of the most extensive weapon factories in the world. Among his other inventions are a battery for submarine harbor defense, and the first submarine telegraph cable.

COLTMAN, Robert, Jr., American physician: b. Washington, 19 Aug. 1862. He was graduated at the Jefferson Medical College, Philadelphia, in 1881 and began the practice of medicine in the same year. In 1896 he became professor of anatomy at the Tung Wen College, Peking, and in 1898 was appointed professor of surgery at the Imperial University of the same city. He was appointed foreign correspondent of the Chicago *Record* in 1900, to which he sent out during the siege of Peking by the Boxers the first message that reached the outside world. He is now the representative of the Standard Oil Company of New York at Pekin, China. He published 'The Chinese, their Present and Future: Medical, Political and Social' (1891), and 'Yellow Crime, or Beleaguered in Peking' (1901).

COLTON, Arthur Willis, American writer: b. Washington, Conn., 22 May 1868. He was graduated at Yale in 1890, held the Foote scholarship there 1890–93, and was instructor in English literature 1893–95. Since 1895 he has devoted himself to writing, and his stories, essays and verse have appeared in the *Atlantic Monthly, Scribner's, Harper's* and other magazines. In book form he has published 'Bennie Ben Cree' (1900); 'The Debatable Land' (1901); 'The Delectable Mountains' (1901); 'Tioba, and Other Tales'

(1903); 'Post Argent' (1904); 'Belted Seas' (1905); 'The Cruise of the Violetta' (1906); 'Harps Hung Up in Babylon' (1907). He was librarian of the University Club, New York, 1906–29.

COLTON, Charles Henry, American Roman Catholic prelate: b. New York, N. Y., 15 Oct. 1848; d. Buffalo, 9 May 1915. In the schools of that city he pursued his elementary studies, later attended the Latin school connected with Saint Stephen's Church, and in 1869 began a theological course at Saint Francis Xavier's College. After three years he repaired to Saint Joseph's Diocesan Seminary, Troy, N. Y., where he was ordained priest 10 June 1876. He was then made assistant pastor of Saint Stephen's Church, New York, and, in 1886 assumed charge of the church of Our Lady of Mercy, Port Chester, N. Y. In 1887 he was recalled to New York to aid the Rev. A. J. Donnelly of Saint Stephen's. Father Colton was named administrator of the parish, and subsequently appointed rector. In 1896 Archbishop Corrigan appointed him chancellor of the New York diocese and upon Bishop Quigley's promotion to the archbishopric of Chicago, Ill., the Holy See chose Father Colton to succeed him as bishop of Buffalo. He was consecrated in New York by Archbishop (later Cardinal) Farley, 24 Aug. 1903.

COLTON, Gardner Quincy, American scientist: b. Georgia, Vt., 7 Feb. 1814; d. Rotterdam, Holland, 11 Aug. 1898. He discovered the anæsthetic properties of nitrous oxide, or "laughing gas," credit for which is also given to Dr. Horace Wells. He perfected an electric motor in 1847.

COLTON, George Radcliffe, American public official: b. Galesburg, Ill., 10 April 1866; d. 7 April 1916; educated, Knox College, was a ranchman in New Mexico in 1881–86, member of the Nebraska House of Representatives, 1889–90 and national bank examiner for the district of Nebraska in 1897. He went to the Philippine Islands as lieutenant-colonel of the First Nebraska Volunteer Infantry, organized the customs service at Manila upon the American occupation and served with it until 1905, when he went to the Dominican Republic and organized the Dominican customs receivership under the modus vivendi between the United States and the Dominican Republic. In 1907–09 he was insular collector of customs for the Philippine Islands. He drafted and presented to Congress the tariff for the Philippines, enacted by special session of Congress 1909, and also took part in drafting provisions of the Payne Bill relating to free trade between the United States and Philippines. In 1909–13 he was governor of Porto Rico.

COLTON, Walter, American writer: b. Rutland, Vt., 9 May 1797; d. Philadelphia, Pa., 22 Jan. 1851. He became professor of moral philosophy and *belles-lettres* at Middletown Academy, Conn. (1825); in 1828–30 was editor of the *American Spectator,* Washington. In 1845 he went to California, and in Monterey established the first newspaper of the State, called the *Californian.* He wrote several books of interest, including 'Ship and Shore in Madeira, Lisbon and the Mediterranean' (1835); 'Visit to Athens and Constantinople' (1836); 'Three Years in California' (1850); 'Deck and Port' (1850); 'The Sea and Sailor' (1851).

COLTON, kōl'tŏn, Calif., city in San Bernardino County; alt. 847 feet; 57m. SE. of Los Angeles; on the Atchison, Topeka and Santa Fe; Southern Pacific; and Union Pacific railroads. Great quantities of fruit and garden truck are shipped from here, and flour, cement, concrete conduits, wines and candy are manufactured. Colton was a station on the old Santa Fe Trail and an early railroad terminus. Pop. (1940) 9,686.

COLUBRIDÆ, kō-lū'brĭ-dē, a family of snakes, typified by the limited genus *Coluber* of Linnæus, which comprises nine-tenths of all living snakes. As arranged by Cope the family contains non-venomous snakes (*Aglypha*) only, but under Boulenger's more approved system it embraces both the *Opisthoglypha* and *Proteroglypha,* which include all the poisonous snakes except the vipers and pit-vipers (qq.v.). Even in the limited sense, a vast majority of snakes, not less than 1,000 species, fall within the family. All are of relatively small size, only a few giants attaining a length of 10 feet, and all have continuous rows of small teeth in both jaws, and none enlarged to serve as poison fangs. The head scales are large non-imbricate plates, but the body scales usually overlap, tile-like. They are oviparous or ovoviviparous and feed on insects, small mammals, birds, etc., though a few, as the king-snake, habitually devour poisonous serpents. Most of them are terrestrial, but some are aquatic and others arboreal. Nearly cosmopolitan in their distribution, but very sensitive to the influence of cold, they are absent from the polar regions, and in temperate climes hibernate during the winter. Many species are found in North America. (See BLACKSNAKE; CORNSNAKE; GARTERSNAKE; PINESNAKE; WATER-SNAKE; etc.). Consult books mentioned under SNAKE, especially Cope, 'Snakes of North America' (Ann. Rept. Smiths. Inst. 1898, Washington 1900); and Gadow, 'Amphibia and Reptiles' (New York 1901); 'Catalogue of Snakes of the British Museum,' where full references will be found.

COLUGO, kō-loo'go, **COBEGO,** kō-bā'gō, or **KAGUAN,** kä'gwän, an East Indian insectivore of the only genus of the family *Galeopithecidæ,* as yet imperfectly known. It is a slender creature about 18 inches long, its body covered with peculiarly sleek fur and provided with a parachute of membrane furred on both sides and extending from the neck nearly to the tip of the tail, by which it is enabled to make long sailing leaps like a flying-squirrel, a feature which gives it its technical name, *Galeopithecus volitans.* Like the bat, which the colugo resembles in various actions, it is a creature of twilight, hanging suspended by its hind legs from branches during the glare of day and seldom venturing forth in the complete darkness of night. It feeds upon leaves, fruit and insects. Consult Moseley, 'Notes by a Naturalist on H. M. S. Challenger'; Wallace, 'Malay Archipelago' (New York 1869).

COLUMBA, Saint, apostle of the northern Picts of Caledonia and founder of numerous monasteries in the Hebrides and the Scottish mainland: b. 7 Dec. 521 in the territory of the Kinel-Conal, modern Donegal. He was a scion

of the illustrious race of Conal and was thus of kin to the northern princes of Ireland and of the Gælic princes of Scotland. Whether his name, or surname, Columba, is Latin or a Latin modification of a Gælic name cannot be determined; it appears also in the form Colm (whence the name Malcolm, servant or devotee of Columba); and the saint is also known as Columkillé (Columba of the churches, or *cellae*, the c in Gælic being equal to k), because of the great number of churches and monasteries he founded both in Ireland and in Scotland and the isles. He became a monk in his youth in the monastery of Moville in Donegal, and at the age of 30 was a priest. Among the monastic establishments founded by him in Ireland are those of Daire-Calgaich (Calgach's oak grove), the site of the famous city of Derry or Londonderry; and Dair-mach (oak of the plain) where now is Darrow. This was the greatest of all his Irish monasteries. It is worthy of note that after his migration to Scotland, he and his immediate successors in Iona exercised jurisdiction over these Irish monasteries. About the year 563, being then under excommunication for the part he had taken in the bloody battle of Cooldrevny, he set sail for North Britain with a band of his monks to preach the Christian religion to the still pagan Picts of northern Caledonia. He was entertained hospitably by his kinsman, Conal, king of the Scots in Argyll (Airer-Gædhill, land of the Gæl) who gave him for his residence the island in the Hebrides later called I, or Iona and I-Columkillé. Having established in Iona a monastery and training-school of missionaries, he crossed over to the country of the northern Picts — the southern Picts had already been converted to Christianity — and to them preached the gospel with such effect that their king Brude and the whole people embraced the faith. Before Columba's death all northern Caledonia was Christian and monasteries were very numerous whether on the mainland or in the islands. Iona was the mother house, and thence Columba and his successors, abbots of Iona, governed not only the monastic houses but the churches also; and though there were bishops for the special functions of the episcopate — the ordering of priests, for example, the administering of confirmation, the consecrating of churches and the like — those bishops were subject to the authority of the abbot of Iona, though he was never more than a presbyter in ecclesiastical order. What time was at his disposal amid the many cares of his station, Columba devoted to study and to transcription of the Scriptures. On 8 June 597 he was employed in this labor, transcribing the psalm Benedicamus Domino (the 33d in the Septuagint and the Vulgate, but the 34th in the authorized English version); after penning the words «Inquirentes autem Dominum non minuentur omni bono» — they who seek the Lord shall want no manner of thing that is good. «Here,» he said, «I must stop; what follows let Baithen write,» and laid down the pen. At the midnight hour he was in choir for the office of Matins, having come to the church unaided and knelt at the altar; through sleep he in a few moments passed to death. Three Latin hymns are attributed to him, and, in addition, some Celtic poems. The story of his life and miracles was told first by Cuimine Ailbhe, who was also abbot at Iona (printed at London 1789 and at Paisley 1889). Based on this account Adamnan, the ninth abbot, wrote another 'Vita Sancti Columbæ' (edited by Reeves, Dublin 1857; J. T. Fowler, London 1894–95). Consult Troup, 'Saint Columba; the Lord's Song in a Strange Land' (London 1913).

COLUMBA, or **COLUMBA NOACHI,** nō-ā'kī (Lat. «Noah's dove»), a small constellation of stars south of Lepus and Canis Major, about the time of whose discovery there are different statements. It is generally believed that it was first named by Royer in 1679 or 1680. This is easily disproved by the fact, seldom noted, that Bayer in his 'Uranometria,' published in 1603, on the 37th map, just below Canis Major, pictures the dove flying with the olive-branch in its mouth. Dr. Gould states that it was mentioned by Petrus Plancius, an eminent Dutch geographer and teacher of Petrus Theodori. The latter died in 1596. The constellation is known to-day by the simple name of Columba, and is situated between Puppis, Pictor, Cælum, Lepus and Canis Major.

COLUMBÆ, a sub-order of charadriiform birds containing the pigeons, fruit-eating pigeons, sand-grouse, etc. The typical family is *Columbidæ,* or true pigeons and doves. See PIGEON.

COLUMBANUS, kŏl-ŭm-bā'nŭs, missionary and founder of a monastic order, that of the Columban monks, was born in Ireland about 543; died in his monastery of Bobbio, in the Apennines, Italy, 21 Nov. 615. The order founded by him was for a while hardly inferior to the order of Saint Benedict in number of monasteries or in the services it rendered to the Church. He was an alumnus of the great monastery of Benchor or Bangor, in Ulster, and thence in his 45th year he went to France as a missioner, accompanied by 12 young disciples. In France he founded the monasteries of Luxeuil, Arnegray and Fontenay, giving to the monks a rule identical with that of the Celtic monasteries of Ireland. He gave offense to the French bishops by the fashion of his tonsure and by his observance of Easter in accordance with the calculation of the Eastern churches. And his apostolic outspokenness in rebuking the vices of the Burgundian court, the king (Thierry II) and the queen mother (Brunehaut) led to his expulsion from that country. He now decided to cross the Alps and labor as a missionary in Italy. On his route thither he tarried a while among the Swiss, preaching the gospel on the shore of Lake Constance. One of his 12 companions, named Gallus, falling sick, was left behind when the missionary party resumed their travel: this Gallus afterward laid the foundations in Switzerland of a monastic institute which later was called by his name, Saint Gall (Sankt Gallen) and which was one of the notable centres of monasticism in Europe. Columbanus, in 612, founded the great monastery of Bobbio in the Apennines, giving to the monks of that house, which soon was recognized as the mother-house of a multitude of abbeys and monasteries, a rule of great austerity. The keynote of it is implicit, unquestioning obedience in all things to the abbot or su-

perior. It prescribes perpetual silence save where speech is absolutely necessary. The use of animal food of all sorts is interdicted. The monks are allowed one meal daily, taken at eventide, and it consists of vegetables and bread. The monks of his monasteries, called Columbans, came under the Benedictine rule in the 8th century and the Columban order was merged in the Benedictine. Columbanus was a man of learning, acquainted not only with the Latin language current in his time, but with the classic Latin authors, as also with the Hebrew and Greek languages. He left a few writings, all in Latin; they have all been published more than once. They comprise his Monastic Rule (Regula Cœnobialis); a few poems of considerable merit; 16 brief sermons and several letters of value for ecclesiastical history. A town in Lombardy, San Colombano, perpetuates the memory of this Celtic missionary to Italy.

COLUMBIA, the popular name of the United States; derived from Columbus and applied to the greatest nation of the New World from a feeling of poetic justice to the memory of its great discoverer.

COLUMBIA, British. See BRITISH COLUMBIA.

COLUMBIA, District of. See DISTRICT OF COLUMBIA.

COLUMBIA, Miss., city and Marion County seat; alt. 145 feet; on Pearl River; 90m. S. of Jackson; on the Illinois Central; Fernwood, Columbia and Gulf; and Gulf, Mobile and Northern railroads. Formerly a lumber town, the cut-over lands near by have been developed agriculturally, producing cotton, potatoes, tung oil, poultry, and cattle. Its manufactures include clothing, canned foods, veneer and plywood, and naval stores. There is a public library. Columbia has the mayor-council form of government. Pop. (1940) 6,064.

COLUMBIA, Mo., city and Boone County seat; alt. 783 feet; 35m. N. of Jefferson City; on the Wabash; and Missouri, Kansas and Texas railroads. It has a municipal airport. The surrounding region has coal mines; and raises grains, garden truck and dairy cattle. In the city, flour, dairy products and airplane propellers are manufactured. Columbia is primarily an educational center. Here are located the University of Missouri (q.v.); Stephens College (1856; Baptist); and Christian College (Disciples, 1851); the last two junior colleges for women. Settled about 1821, the city was incorporated in 1826. Pop. (1940) 18,399.

COLUMBIA, Pa., borough in Lancaster County; alt. 255 feet; on the Susquehanna River and on the Pennsylvania and the Reading railroads; 13m. NE. of York. Situated in rich farming country, it is important as a trading center and shipping point. Industries include foundries, rolling mills, stoves, textiles, and cut glass. The town has a public library. Columbia was first settled in 1726 by John Wright, a Quaker, and was known as Wright's Ferry. In 1789, when possible locations for the national capital were being discussed, this was one of the places to which consideration was given, and it was at this time that the name was changed to Columbia. In the middle 1800's Columbia was a lumber center, logs being floated down the Susquehanna from the forests of northern Pennsylvania. The Pennsylvania Canal and the railroad to Philadelphia, completed in 1834, brought activity to Columbia. Government is administered by a burgess and council. Pop. (1930) 11,349; (1940) 11,547.

COLUMBIA, S. C., state capital, and seat of Richland County; alt. 351 feet, 129 miles northwest of Charleston, in the center of the state, on the east bank of the Congaree River, at the head of navigation, two miles below the junction of the Broad and Saluda. It is on the Atlantic Coast Line, the Seaboard Air Line and the Southern railroads, and on two federal highways—U.S. highways Nos. 1 and 21.

Topography.—Columbia is handsome and clean for an industrial center. It is built on a sand-hill bluff 100 feet high at the river and sloping away on all sides, giving excellent drainage. The streets, 100 feet wide, run at right angles to each other; four avenues 150 feet wide radiate from the capitol. The chief streets are boulevards, with handsome shade-trees along the sides and in the center. The city was carefully planned and laid out.

Public Buildings.—The granite State House, costing $4,000,000 and modeled on the capitol at Washington, was begun in 1855, was cannon-scarred in 1865, and was completed in 1903. Spacious grounds surround the capitol. The city's monuments include a «Palmetto Tree» in bronze. The executive mansion, the government building, the county courthouse, the city hall, Federal Land Bank building, the municipal auditorium (seating 4,000), and state penitentiary are noteworthy. A U.S. Veterans Hospital just outside the city, completed in 1932, has 13 buildings and 600 beds. The State Hospital's first building (1822) was designed by Robert Mills, famous for the Washington monuments in Washington, D. C., and Baltimore. There are several historic churches. The First Baptist Church (1811) Greco-Roman in style, was the meeting-place of the Secession Convention in 1860. Trinity Episcopal (1814), an imitation on a small scale of York Minster, has the graves of Henry Timrod, who wrote Confederate war poems, and of Wade Hampton, Confederate cavalry leader, whose home, Millwood, on Sumter Road, was burned in the Civil War—the ruins are still a show place. The First Presbyterian Church (1814) has in its burying ground the graves of President Woodrow Wilson's father and mother. And the Wilson home, designed by the President's mother, is open to the public. His father taught in the Presbyterian Theological Seminary. The city is rich in important educational institutions: South Carolina College, now the University of South Carolina, founded 1801; the Presbyterian Theological Seminary, 1828; Southern Lutheran Theological Seminary, 1830, in the suburb of Eau Claire; Columbia College for Women (Methodist Episcopal South), founded 1854; Allen University (African Methodist Episcopal), 1881; Benedict College (Baptist, Negro, co-educational), 1870. The city has its own town theater. Modern housing projects include one for Negro families.

Municipal Conditions.—The principal streets have good pavement. Until 1805 Columbia was governed by the legislature. Then it became an incorporated village, and in 1854 it was char-

tered as a city. It has a commission government with a mayor and four councilmen elected every four years.

Business Interests.—The city is a remarkable instance of manufacturing development. It is in the heart of a fertile cotton district and near forests of pine, oak, walnut, and maple. In 1815 the improvement of the Broad, Saluda, and Congaree rivers was begun. The Columbia Canal was finished in 1824. The city then became an important transportation and trade center, especially for up-country cotton. In 1842 Columbia was connected by rail with Charleston on the coast and with Hamburg on the Savannah River. A rocky shelf projecting for four miles from the junction of the Broad and Saluda forms the bed of the Congaree, 500 feet wide, which plunges down it in rapids, with a fall of 36 feet in the immediate vicinity of the city. It affords 14,000 horsepower, made available by a canal 2⅞ miles long, 110 feet wide at bottom and 150 feet at top, with 31 feet fall. A hydroelectric plant was completed in 1931 by building Saluda Dam, 208 feet high, nearly 1½ miles long, with a base width of 1,150 feet. This earthen dam is the largest of its type. It created Lake Murray, an artificial body of water 41 miles long, 14 miles wide, with a shore-line of 520 miles. This impounding gave an initial output of 200,000 horsepower. The largest factories are independent of this except in emergency, using steam dynamos. In 1892, there was one cotton mill in the city employing 125 men. Now the two largest cotton manufacturers in Columbia, Whaley and Columbia Mills, have a capitalization of over 4½ million dollars. The Olympia Mill (Whaley) is one of the world's largest under a single roof. Besides cotton goods (especially duck) hosiery is made here. Glass works utilize the fine sand found near by. Four quarries supply fine granite—the State Capitol is built of Columbia granite. There are large lumber works.

A floating dam 15 feet high enables vessels of 10 feet draft to come up to the city instead of unloading at Granby. This improvement makes Columbia the great distributing point for central and northern South Carolina.

History.—The site was settled about 1700, but remained farm land till 1786, when the people of the State demanded a capital more centrally located than Charleston, and Columbia village was laid out—a victory for the Piedmont section of the state. The legislature first met here in 1790, and in May and June of that year a constitutional convention meeting in the State House framed a new constitution in force until 1865. Before the Civil War cotton manufacturing had begun here as the crop was transferred at this point from wagons for water carriage. In the Civil War it shared the general fortunes of the State until February 1865, when it was shelled by Sherman from a position across the Congaree River. Sherman's army entered it 17 Feb. 1865 after the formal surrender. On that night a fire broke out which lasted all the next day and laid two thirds of the city in ashes and destroyed a great quantity of cotton. The area of the city was increased by annexing suburbs in 1913, 1925, 1926, and 1927. Pop. (1830) 3,310; (1860) 8,052; (1870) 9,298; (1880) 10,036; (1890) 15,353; (1900) 21,108; (1910) 26,319; (1920) 37,524; (1930) 51,581; (1940) 62,396.

COLUMBIA, Tenn., city and Maury County seat; alt. 650 feet; on the Duck River; on the Louisville and Nashville; and the Nashville, Chattanooga and St. Louis railroads; 46m. S. of Nashville. It is the trading center of a dairy farming region. Its industrial products are hosiery, work clothing, electrodes, and elemental phosphorus. Settled in 1807, Columbia was incorporated in 1817. Government is by city manager and commissioners. Pop. (1930) 7,882; (1940) 10,579.

COLUMBIA, or OREGON, after the Yukon, the largest river on the western side of America. It rises in the Kootenay District of British Columbia, on the western slope of the Rocky Mountains, near mounts Brown and Hooker, in about lat. 50° N. Its course, which is very irregular, is generally southwest through British Columbia and Washington. It forms the northern boundary of Oregon for about 350 miles and enters the Pacific by an estuary 35 miles long and from 3 to 7 wide. Its estimated length is 1,400 miles, and the area drained by it and its tributaries, of which the largest are Clark's Fork (with the Missoula, 700 miles long), and the Snake River (940 miles in length) along which are very remarkable canyons, has been computed to be 298,000 square miles. The river is broken by falls and rapids into separate portions, and formerly a bar across its mouth obstructed navigation. The construction of a jetty two and one-half miles long has provided a good harbor, but the silt deposit calls for constant dredging and other work. Sea-going vessels ascend the Columbia for 100 miles to the Willamette and from the junction with the latter to Portland (10 miles), while steamboats reached the Cascades (160 miles), where there was a portage of 6 miles which was bridged over by a railway; and beyond this another navigable stretch of 50 miles to the Dalles. In November 1896 the government completed a canal and locks at the Cascades, at an expense of nearly $4,000,000, and thus opened navigation to the Dalles, where a 14-mile railroad passes round the Great Dalles channel to the next section above (185 miles), beyond which there is a final part navigable for 250 miles by steamboats. The Columbia and its branches have 2,132 miles of navigable waters. The salmon fisheries are well exploited. Captain Gray of Boston entered the river in 1792, and Lewis and Clark explored it in 1805.

COLUMBIA CITY, Ind., seat of Whitley County, alt. 841 feet, 20 miles west of Fort Wayne, on the Pennsylvania Railroad and the Lincoln Highway. It manufactures woolens, overalls, auto and airplane parts and distributes farm products, notably onions and mint. It has a mayor and council. Pop. (1940) 4,219.

COLUMBIA HEIGHTS, Minn., city of Anoka County on the left bank of Mississippi River; adjoins Minneapolis. Pop. (1940) 6,035.

COLUMBIA PLATEAU, a broad upland region lying in Washington, Oregon and Idaho. It averages about 3,500 feet in elevation, but is deeply trenched by Columbia and Snake River Canyons. The plateau, which lies between the Rocky Mountains and the Cascades, consists of broad level expanses of Tertiary

lava flows. The southern part is a desert. In the north, particularly in the Big Bend country, considerable wheat is raised. The mineral wealth is very limited.

COLUMBIA RIVER HIGHWAY, a 60-mile scenic highway leading out of the city of Portland, Ore., to Hood River, and traversing the notably picturesque scenery along the Columbia River. The engineering work has been carried out with the most careful observance of artistic possibilities and effects, and the results are hailed as a model for similar enterprises. The roadway is 18 feet in width, of bitulithic pavement, and the steepest grade does not exceed 5 per cent. The highway joins the Lincoln Highway at Cheyenne and forms a link in the route through Yellowstone Park.

COLUMBIA SALMON. See SALMON.

COLUMBIA UNIVERSITY, a seat of learning in New York. The idea of establishing a college in New York was more than 50 years in contemplation before it was carried into effect. In 1746 provision was made by law for raising money by public lotteries. Five years later the proceeds of these lotteries amounted to about $1,700 and were given to trustees. The fact that two-thirds of these trustees were in communion with the Church of England and that some of them were vestrymen of Trinity Church excited opposition to the proposal as a scheme to strengthen the Established Church and delayed the procurement of a royal charter. Friends of the enterprise proceeded, however, with the arrangement for opening the college and elected for their first president the Rev. Dr. Samuel Johnson of Stratford, Conn., who assumed the office 17 July 1754, in the schoolhouse belonging to Trinity Church. There was a class of eight students.

The cosmopolitan character of the governing body of the college is due to its charter. To meet the objections that had been made, it was so drawn as to include in its board of governors, besides other ex officio representatives, not only the rector of Trinity Church, but the senior minister of the Reformed Protestant Dutch, Ancient Lutheran, French and Presbyterian churches. It is probably due to this circumstance that Columbia almost alone of all the pre-Revolutionary colleges in the United States has never had a theological faculty connected with it. The trustees, at present, are members of the Episcopal Church, and also of the Reformed, Presbyterian and Roman Catholic churches, showing that this cosmopolitan character has never been lost. A prominent Hebrew rabbi was at one time a member of its councils.

The charter of King's College, the original name of Columbia, was granted by George II, and finally passed the seals on 31 Oct. 1754, from which day the college dates its existence. It received from Trinity Church, according to a promise previously given, a portion of a grant of land known as «the King's Farm,» upon the site of which its first building was erected. It was stipulated in the royal charter that its president should be a communicant of the Episcopal Church and that proper selections from the liturgy of that church should be used in the religious services of the college. This caused much angry controversy, and after the Revolution it was stricken out of the charter, but remains as the condition of the deed of gift from Trinity Church. King's College played a conspicuous part in securing and confirming the independence of the United States. The Revolutionary War caused a suspension of the activities of the college, and in 1776 the college building was used as a military hospital. After eight years the college work was resumed by act of the legislature, 1 May 1784, under the name of Columbia College.

On 13 April 1787 the legislature revived the original charter with amendments, which abolished ex officio membership of its governing body, canceled the requirement that the president should hold a certain form of religious belief or that a certain form of prayer should be used in the services of the college, and named a body of 29 trustees, which, when reduced to 24 members, was made a self-perpetuating body, under which government the college has remained. The medical faculty was organized in 1792 and a professorship of law was established in 1793.

The original site of the college was in what became later the block bounded by College Place, Barclay, Church and Murray streets. In 1857 the college was moved to 49th and 50th streets and Madison avenue, where it remained until 1897. In 1892, for $2,000,000, purchase was made of 17½ acres of land lying between 116th and 120th streets, Amsterdam avenue and the boulevard. Here in 1897 the college was reorganized on the basis of a university.

Columbia University, in a technical sense, consists of the faculty of law, the first professor of which (1792), James Kent, during the period of his second appointment in 1823 delivered the courses of lectures which developed into the first two volumes of his famous 'Commentaries'; the faculties of medicine; philosophy, political science; pure science and engineering. The College of Physicians and Surgeons, the outcome of the medical faculty, established in King's College in 1767, became in June 1860 the Medical College of Columbia. In 1891 it surrendered its separate charter and is now the medical school of the university. A peculiarity of the Columbia organization is the system by which seniors in Columbia College, who have entered the college not later than the beginning of the junior year, are allowed to select part or all of the courses necessary for the bachelor's degree from among those designated by the university faculties, professional or non-professional, as open to them. The object of this arrangement is to shorten the time necessary to the attainment of the higher, particularly of the professional, degrees. The degree of master of laws is conferred for advanced work in law done under the faculties of law and political science together. The faculties of law, medicine and applied science conducted respectively the schools of law, medicine and mines, chemistry, engineering and architecture, to which students were admitted as candidates for professional degrees on terms prescribed by the faculties concerned. The school of mines was due to the exertions of Thomas Egleston, who was made professor of mineralogy and metallurgy in 1864, and who opened the school of mines the same year in the basement of the old college building in 49th Street. There was also the school of chemistry, engineering and architec-

ture, set off from the school of mines in 1896. Out of the school of mines, now embraced in the school of engineering, grew the school of pure science (est. 1892) which is now grouped in the faculties of political science, philosophy and pure science. Architecture is a separate school. In 1912 a school of journalism was established, and in 1916, a school of business. Other departments are: school of dental and oral surgery; school of library service; the general course; summer session; university extension. The founding of Barnard College for women was approved by the trustees in 1889. Teachers College, founded in 1888, was included in the university in 1898. (See COLLEGES FOR TEACHERS.)

The College of Pharmacy, and Bard College at Annandale-on-Hudson are also separate corporations, affiliated in the same way as Barnard and Teachers colleges. All degrees granted in the affiliates are conferred by Columbia University The teaching staff in 1937–38 numbered 2,796, while the registration of resident students, including Barnard, Teachers, Pharmacy, summer session of 1937 and university extension numbered 32,619. Total resources were $158,868,638; capital endowment, $88,980,474; annual budget, $15,756,444. The library contains 1,214,524 volumes.

The Presidents of the University have been: Samuel Johnson (1754–63); Myles Cooper (1763–75); the Rev. Benjamin Moore (1775–76); William S. Johnson (1787–1800); Charles H. Wharton (1801); the Rt. Rev. Benjamin M. Moore (1801–11); William Harris (1811–29); William A. Duer (1829–42); Nathaniel Moore (1842–49); Charles King (1849–64); Frederick A. P. Barnard (1864–89); Henry Drisler, acting (1889–90); Seth Low (1890–1901); and Nicholas Murray Butler (inaugurated 1902).

PHILIP M. HAYDEN,
Secretary, Columbia University.

COLUMBIA UNIVERSITY SCHOOL OF MINES. See COLUMBIA UNIVERSITY.

COLUMBIAN COLLEGE. See GEORGE WASHINGTON UNIVERSITY, THE.

COLUMBIAN FORMATION, a series of gravels, sands and clays of Pleistocene Age covering the coastal plain of the Atlantic slope from New Jersey southward and typically developed in the District of Columbia. The formation in the north covers the plain up to elevations of 400 feet, and in the south up to 100 feet. It includes estuarine and delta deposits, and the fossils are recent marine and terrestrial species, indicating a very slight submergence and re-elevation of the coast. The formation may correspond to the Champlain stage of the glaciated portion of the continent. See CHAMPLAIN STAGE; GLACIAL PERIOD.

COLUMBIAN UNIVERSITY. See GEORGE WASHINGTON UNIVERSITY, THE.

COLUMBIAN WORLD'S FAIR. See WORLD'S COLUMBIAN EXPOSITION.

COLUMBIDÆ, kō-lŭm'bĭ-dē, the family of true pigeons, the typical one of the order *Columbæ,* of which it embraces the bulk of the known species, more than 300 belonging to this family of true pigeons and doves. Over half of them are found in the Malayan and Austro-Malayan Archipelago, and 75 in South and Central America, while all other parts of the world, except the polar regions, have their representative species in smaller numbers. Although our native species give but a faint idea of the richness of color and other peculiarities of adornment of the tropical pigeons, the structural features are remarkably constant and well exemplified in the domestic pigeon. The bill is moderate and compressed, having at its base a soft skin in which the nostrils are placed. The feet have three divided toes before and one behind, all of which are on the same level; the tarsi scutellate. The wings are rather long and exceptionally powerful; the plumage generally compact and the feathers without aftershafts. One of the most variable features is the tail, which may be short and square or long and pointed, and its rectrices from 12 to 16. Although classed by Cuvier with the gallinaceous birds, the *Columbidæ* differ from them in structure and especially in habits, being monogamous and good flyers. Besides they are unlike the domestic fowl which is the type of the *Gallinæ,* in that the males assist in nest-building and incubation and the young are not able to walk, and are nourished by the parent birds, which secrete in the double crop a milky fluid utilized to soften their food. Moreover the *Columbidæ* drink at a single draught. They eat seeds and berries, more rarely insects. See DOVE; PIGEON; etc.

COLUMBINE, a popular name for *Aquilegia vulgaris* or other species of the genus *Aquilegia.* The common columbine has drooping purplish-blue flowers with five flat sepals; five petals, with long spurs, often curved; five follicles; the root-leaves twice or thrice ternate, the others once ternate. Numerous species of the genus occur in North America. *A. cærulea,* the Rocky Mountain columbine, with very large, sky-blue flowers, the showiest plant of the genus, is the State flower of Colorado.

COLUMBITE, a mineral of variable composition, consisting of a compound niobate (columbate) and tantalate of iron and manganese. When niobium is present in large amount relatively to the tantalum, the mineral is called "columbite," and when the reverse is the case, it is called "tantalite"; the two minerals passing into each other, in nature, by insensible gradations. Typical columbite has a hardness of 6, and a specific gravity of from 5.4 to 5.8, the specific gravity increasing with the proportion of tantalum present. The crystals are short and prismatic, often tabular and belong to the orthorhombic system. The mineral is black or brownish-black in color and is often iridescent. In the United States columbite is known to occur in most of the States lying near the Appalachian Mountain system and also in Colorado, South Dakota and California. One crystalline mass of it, found in the Black Hills region, is said to have weighed about a ton. The existence of columbite in the United States was first made known through a specimen sent by Governor Winthrop of Connecticut to Sir Hans Sloane, president of the Royal Society of Great Britain.

COLUMBIUM, a metallic element, better known as niobium. It was discovered by Hatchett in 1801 and named columbium and rediscovered by H. Ross in 1846 who named it niobium. It is found in small quantities in various minerals; but principally in columbite and tantalite. Columbium has been found in various parts of the United States, Sweden,

Mexico and other Central and South American countries. It is a very hard metal, especially when combined with carbon, its normal condition. It was called niobium on account of its resemblance to tantalum with which it occurs. The allusion to the name is classical as Tantalus was the father of Niobe. Chemical symbol Nb; atomic weight 93.5. It is a brilliant metal of steel-gray color. Chemically it is akin to bismuth.

COLUMBO, the root of a climbing plant, *Jateorrhiza columba,* of the family *Menispermaceæ,* which grows in great profusion in the island of Mozambique. It is also called calumba. The root, sliced transversely into discs, is dried and used in medicine in the form of an infusion as an appetizer and tonic. It contains a bitter alkaloid, *berberine,* and another bitter principle, *columbin.* It is free from tannic acid, so, unlike most bitters, it may be mixed with the preparations of iron. It was formerly employed for diarrhœa, dysentery and gas in the bowels, being carried to India, whence it is exported.

COLUMBUS, Bartholomew (Sp. Bartolomeo Colón; It. Bartolommeo Colombo, his real name), Italian navigator, brother of Christopher Columbus: b. Genoa before 1455; d. San Domingo, 12 Aug. 1514. The events of his early years are not on record. In 1470 we find him established at Lisbon as a mariner and constructor of maps — one of those adventurous navigators whom the patronage of the Portuguese princes had drawn to their capital. About 1486 he visited the Cape of Good Hope, probably with Barthelemi Diaz. His brother sent him to England to seek the aid of Henry VII in 1488, but it appears certain that Christopher was ignorant of his fate, further than that he was captured by pirates. He did, however, attain the ear of the English monarch and presented him with a map of the world, but it does not appear that he succeeded in securing English aid. On his return to France, where he became cartographer to Anne de Bourbon (de Beaujeu), he learned that his brother had already discovered the new world and had sailed on a second voyage (1493). Hastening to the Spanish court, he was received as became the brother of the admiral. Queen Isabella sent him in command of three store ships to the new colony of Hispaniola (1494) where Christopher received him with joy and appointed him adelantado or lieutenant-governor of the Indies. In this position Bartolommeo showed great bravery and decision. He shared his brother's imprisonment, and with him was liberated on reaching Spain, where the Spanish monarchs confirmed his title and gave him the lordship of the small island of Mona near San Domingo, with 200 Indians as his personal body-guard. The fierce energy of his character, however, made them jealous of giving him too much latitude in public affairs.

COLUMBUS, Christopher (Sp. Cristóbal Colón; It. Cristoforo Colombo, his real name), Italian navigator, the discoverer of America: b. Genoa probably 1451; d. Valladolid, Spain, 20 May 1506. His father, Domenico Colombo, a poor weaver, gave him a a careful education in that trade — better characterized as an industrial art or handicraft, highly regarded in Italy during the 15th century, and indeed with good reason esteemed long before and long after the very noble Quattrocento. (See Professor Venturi's account of the Quattrocento or 14th century, in the article ITALY — HISTORICAL SYNOPSIS OF ITALIAN ART). The details of his early life are confused and unsatisfactory. The date of his birth has never been definitely established; different historians range between 1430 and 1456, those most often given being 1436 and 1446. Judging from the ages of his younger brother (b. 1468) and his still younger sister, the year 1451 given above seems the most likely estimate. He is shown by documents cited by Henry Vignaud to have sailed to Chios when about 23 or 24 years of age. Again, in 1476, he sailed for England, and about one year later engaged in commerce at Lisbon. There he married Felipa Moñiz Perestrello, a daughter of a distinguished navigator who had founded a colony in Porto Santo, an island recently discovered and belonging to the Madeira group, and had left many charts and nautical instruments. Columbus made use of these materials, and his opinion that the other side of the globe contained land, belonging to eastern Asia and connected with India, which was, as yet, little known, became more and more fixed. While the Portuguese were seeking to reach India by a southeast course round Africa, he was convinced that there must be a shorter way by the west. He applied in vain to Genoa for assistance, and equally fruitless were his endeavors to interest John II of Portugal in the enterprise. He also sent letters on the subject to Henry VII of England, with the same ill success. He then determined to apply to the Spanish court, Ferdinand and Isabella being at this time the sovereigns of Spain, and after an eight years' struggle with the obstacles thrown in his way by ignorance and malice, he received three small vessels. These were named the *Pinta,* the *Niña* and the *Santa María;* and the documents show the complement of men to have been, for the crews 90, officers and all others 30, total 120. The Capitulations of Granada provided that, after successful accomplishment and conclusion of the adventure — not before — its leader should be advanced to the dignities and offices of peer, admiral and viceroy of such regions as he should or might discover and take possession of — "certain islands in the sea of whose existence Columbus knew." No reference to the Indies appears in records of the negotiations for this great voyage.

It was early in the morning of Friday, on 3 Aug. 1492, that Columbus set sail from the port of Palos. Eighteen years had elapsed since he had first conceived the idea of this enterprise. The most of that time had been passed in almost hopeless solicitation, amidst poverty, neglect and ridicule; the prime of his life wasted in the struggle. Nor should it be forgotten that it was to Isabella alone that he was finally indebted for the means of executing his project, which had been coldly rejected by the prudent Ferdinand. Having provided himself at the Canary Islands with fresh water, he sailed at first due west but later southwest into an ocean never before navigated. But when 21 days had elapsed without the sight of any land, the courage of his men began to sink. It was certain, they said, that they should perish, and their visionary commander ought to

be forced to return. Some of them even proposed to throw him overboard; and Columbus had to exert all the powers of his daring and commanding spirit to quell the mutiny. It seems clear that his triumph in this crisis was due in part to Pinzón's able and loyal assistance. A phenomenon, which surprised even him, filled his pilots with consternation: the needle deviated a whole degree. But the sea appeared suddenly covered with grass, and again showed symptoms of shoals and rocks. Numbers of birds were also seen. Columbus sailed in the direction from which they flew. For some days the voyage was continued with revived courage, until at last the dissatisfaction of the crews began again to break out into open violence; but Columbus, after endeavoring in vain to pacify his men by promises, finally assumed a different tone, and told them it was useless to murmur; that he was determined to persevere. Fully convinced that he must be near the land, he promised a reward to the man who should first catch sight of it. On the night of 11 and 12 October Columbus himself descried a light which sometimes flickered in the distance and sometimes disappeared, and at two o'clock on the morning of the 12th a cannon shot from the *Pinta* announced that a sailor belonging to that vessel had sighted land. That sailor was Rodrigo de Triana.

It was the island of Guanahani, which Columbus believed to belong to eastern Asia, the Indies or India, a belief which he carried with him to his grave. Hence the mistaken names of Indians applied to the natives of America, and that of West Indies applied to the group of islands of which Guanahani forms one. On landing Columbus threw himself upon his knees and kissed the earth, returning thanks to God. The natives collected round him in silent astonishment, and his men, ashamed of their disobedience and distrust, threw themselves at his feet, begging his forgiveness. Columbus, drawing his sword, planted the royal standard, and in the name of his sovereigns took possession of the country, which, in memory of his preservation, he called San Salvador. He then received the homage of his followers, as admiral and viceroy, and representative of the sovereigns. Being informed by the natives that there was a rich gold country toward the south, Columbus directed his course toward that region, and reached Cuba on 28 October, and Española (Hispaniola, Haïti), on 6 December; but as one of his vessels was wrecked and the other separated from him, he resolved to carry the news of his success to Spain. Having built a wooden fort from the wreck of his vessel, he left in it 39 volunteers, and set out on his return, 4 Jan. 1493. The day after he left the island he met the *Pinta,* which had been missing. Both vessels were afterward nearly wrecked in a tremendous storm. Columbus, more interested for his discovery than for himself, wrote an account of his voyage on a piece of parchment, which he secured in a cask, and threw the whole overboard, in the hope that it might be carried ashore. He had hardly finished his work when the gale subsided. On 15 March he re-entered the port of Palos amid the acclamations of the people, the thunder of cannon and the ringing of bells. He hastened immediately to Barcelona, where the court then was, and entered the city in a triumphal procession, with the productions of the newly discovered countries carried before him. A chair was placed for him next to the throne, and, seating himself, he gave an account of his discoveries. He was created a grandee, and all the marks of royal favor were lavished upon him.

On 25 Sept. 1493, he set sail from Cadiz with three large ships of heavy burden and 14 caravels, carrying 1,500 men. On 3 November he discovered the island of Dominica, and afterward Maria Galante, Guadeloupe and Porto Rico, and on the 22d arrived at Hispaniola. Finding the colony he had left destroyed, he built a fortified town, which he called, in honor of the queen, Isabella, and of which he appointed his brother Diego governor. He immediately left the island in order to make new discoveries, visited Jamaica, and returning after a voyage of five months, worn down with fatigue, found to his great joy that his brother Bartolommeo, who had escaped from his captivity, had arrived at Isabella with provisions and other supplies for the colony. Meanwhile a general dissatisfaction had broken out among his companions, who, instead of the expected treasures, had found hardships and labor. They set on foot many calumnies and gave the most unfavorable description of the country and the viceroy. Columbus thought he could not better oppose these reports than by sending considerable treasures to his sovereigns, and for this purpose collected gold from the natives, which was not done without violence and some cruelty. Aguado, a personal enemy of Columbus, was sent as commissioner to investigate the complaints against the great discoverer, who, thinking it time to vindicate himself in the presence of his sovereigns, prepared to return to Spain. Having appointed his brother Bartolommeo adelantado or lieutenant-governor, he embarked for Spain in March 1496 with 225 Spaniards and 30 natives. In Spain calumny was silenced by his presence, and probably still more by his treasures. Yet his enemies were powerful enough to detain the supplies intended for the colony a whole year, and to retard the fitting out of a new expedition.

It was not till 30 May 1498, that he sailed with six vessels on his third voyage. To man these vessels criminals had unwisely been taken — a measure which Columbus himself had advised, and which had been taken up with great satisfaction by his enemies. Three of his vessels he sent direct to Hispaniola; with the three others he took a more southerly direction, for the purpose of discovering the mainland, which information derived from the natives induced him to suppose lay to the south of his former discoveries. He visited Trinidad and the continent of America, the coasts of Paria and Cumana, and returned to Hispaniola, convinced that he had reached a continent. His colony had been removed from Isabella, according to his orders, to the other side of the island, and a new fortress erected called San Domingo. Columbus found the colony in a state of confusion. After having restored tranquillity by his prudent measures, in order to supply the deficiency of laborers he distributed the land and the inhabitants, subjecting the latter to the arbitrary will of their masters, and thus laying the foundation of that system of slavery which has lasted down to our time. His enemies, in

the meantime, endeavored to convince his sovereigns that he had abused his power, and that his plan was to make himself independent, till at last even Isabella yielded to the wishes of Ferdinand, who had previously become convinced of the truth of the slanders. Francisco de Bobadilla was sent to Hispaniola with extensive powers to call the viceroy to account. As soon as he reached the island he summoned Columbus to appear before him and put him in irons. His brothers were treated in the same manner. All three were sent to Spain, accompanied by a number of written charges, drawn up from the statements of the bitterest enemies of Columbus. Columbus endured this outrage with noble equanimity, and wrote, as soon as he had arrived in Cadiz, 25 Nov. 1500, to a lady of the court vindicating his conduct, and describing in eloquent and touching language the treatment he had received. The fetters with which he had been bound he kept to the day of his death, and his son Hernando states that he even ordered that they should be enclosed with him in his coffin. Orders were immediately sent directing him to be set at liberty, and inviting him to court, where his sovereigns received him with the same distinction as formerly. Isabella was moved to tears, and Columbus, overcome by his long-suppressed feelings, threw himself upon his knees, and for some time could not utter a word for the violence of his tears and sobbings. He then defended himself by a simple account of his conduct, and was reinstated in his dignities. Ferdinand even consented to dismiss Bobadilla, which was intended for the first step toward the promised restoration of the great discoverer to his dignities. But these dispositions in the monarchs were soon changed. There was much talk of great expeditions, and in the meantime Nicolas de Ovando y Lares was sent as governor to Hispaniola. Columbus still urged the fulfilment of the promises solemnly made to him; but after two years of delay he became convinced that there was no intention to do him justice.

But he had now learned to suffer, and he was principally desirous of completing his work. Supposing the continent which he had seen to be Asia, he did not doubt that he should find, through the Isthmus of Darien, a way to the Spice Islands, from which the first fleet of the Portuguese had just returned richly laden. In four slender vessels supplied by the court for this purpose, Columbus sailed from Cadiz on his fourth and last voyage, 9 May 1502, with his brother Bartolommeo and his son Hernando; arrived contrary to his original intention off San Domingo 29 June, and was denied permission to enter the port for the purpose of refitting his vessels, and escaping an approaching storm. He succeeded, however, in anchoring his small squadron in a place of safety, and rode out the storm, while a fleet of 18 vessels, which had put to sea in spite of his warning, was almost entirely destroyed. He then continued his voyage to Darien, but without finding the expected passage. Two of his vessels were destroyed by a gale; the two others were wrecked off Jamaica, where he was scarcely able to save himself and his companions. Here the severest trials awaited the constancy of Columbus. Separated from the other part of the world, his destruction seemed to be certain. But he succeeded in procuring a few canoes from the natives, and prevailed on some of his boldest and best men to attempt a voyage to Hispaniola, in two canoes, in order to inform the governor of his situation. Several months elapsed without a glimpse of hope. Part of his companions, reduced to despair, rebelled, repeatedly threatened his life, separated from him and settled on another part of the island. Here they alienated the minds of the natives by such cruel treatment, that the latter ceased to bring them supplies. The death of all seemed inevitable; but Columbus, whose courage rose with the danger, preserved his men in this crisis. He had ascertained that a total eclipse of the moon was about to take place, and threatened the natives with the vengeance of his God if they should persist in their enmity. As a proof of his assertion the moon, he said, would lose its light, in token of the chastisement which awaited them. When they beheld his threat verified they hastened to bring him provisions, and implore his intercession with the Deity. But hostilities now broke out between him and the rebels, in which several of the latter were killed, and their leader was taken prisoner. After remaining a year on the island, relief at last appeared. The two canoes had reached Hispaniola in safety, but the messengers could not prevail on the governor to undertake the deliverance of the admiral. They finally bought a vessel themselves, and it was on board this ship that Columbus left Jamaica, 28 June 1504. He went to San Domingo, but only to repair his vessel, and then hastened back to Spain. He arrived in Spain ill and exhausted. The death of the queen soon followed, and he urged in vain on Ferdinand the fulfilment of his contract. After two years of illness, humiliations and despondency, Columbus died at Valladolid. His remains were transported, according to his will, to the city of San Domingo, but on the cession of Hispaniola to the French they were removed in January 1796, with great pomp, to the cathedral of Havana in Cuba. A splendid monument was erected to him, in a convent at Seville, where his body lay before being transferred to San Domingo. In 1898 his remains were again removed to Spain, Cuba being no longer a Spanish possession since the war with the United States.

In the vigor of manhood Columbus was, according to tradition, of an engaging presence, tall, well formed and muscular, and of an elevated and dignified demeanor. His visage (here also we can be guided only by tradition and relatively late portraits, inasmuch as an authentic contemporaneous portrait probably does not exist) was long, his nose aquiline, his eyes light gray and apt to kindle. His whole countenance had an air of authority. Care and trouble had turned his hair white at 30 years of age. He was moderate and simple in diet and apparel, eloquent in discourse, engaging and affable with strangers, and of great amiability and suavity in domestic life. His temper was naturally irritable, but he subdued it by the benevolence and generosity of his heart. Throughout his life he was noted for a strict attention to the offices of religion; nor did his piety consist in mere forms, but partook of that lofty and solemn enthusiasm with which his whole character was strongly tinctured. Of a great and inventive genius, a lofty and noble ambition, his conduct was char-

acterized by the grandeur of his views and the magnanimity of his spirit.

H. 'Christopher Columbus' (New York 1936); David, M., 'Who Was Christopher Columbus?' (New York 1934).

COLUMBUS, Diego, or Giacomo (It. Giacomo Colombo), Italian voyager: b. Genoa about 1446; d. at Seville, 21 Feb. 1515. He was a brother of Christopher Columbus, whom he accompanied on the second voyage to America, in 1493. He was sometimes left in command at the settlements of Isabella and San Domingo and returning to Spain in 1500, subsequently entered the priesthood.

COLUMBUS, Diego (Sp. Colón, kō-lōn'): b. probably at Lisbon about 1476; d. Montalvan, near Toledo, Spain, 23 Feb. 1526. He was a son of Christopher Columbus (q.v.) and from 1492 to 1504 was a page at the Spanish court. In 1508 he married into the famous and influential Alba family and through his wife's influence he was confirmed admiral of the Indies and governor of Hispaniola in 1509, where he ruled with great pomp and splendor. Throughout his life he continued his claim to the office of viceroy of the Indies which had been conferred upon his father; and this kept him in a constant legal battle in which his opponents generally got the better of the fight, until 1520 when he finally won the contest; only, however, to hold his hardly won prize until 1523, when he was summoned back to Spain, where he died three years later.

COLUMBUS, Ferdinand (Sp. Ferdinando Colón, fĕr-dē-nän'dō kō-lōn'), Spanish voyager: b. Cordova, Spain, 15 Aug. 1488; d. Seville, 12 July 1539. He was a son of Christopher Columbus, whom he accompanied on his fourth voyage 1502–04. His library of 20,000 books was bequeathed to the cathedral chapter of Seville and was known as the «Columbina.» But 4,000 of these now remain and the history of the Indies by him is also lost, as well as the original Spanish of his life of his father, largely drawn upon by Las Casas. This is the basis of the majority of the 'Lives' of Columbus.

COLUMBUS, Luis, loo-ēs' (Sp. Colón), Spanish noble: b. San Domingo 1521 or 1522; d. Oran, Africa, 3 Feb. 1572. He was a son of Diego Columbus 2d (q.v.), and a grandson of Christopher Columbus. He was given the title of admiral of the Indies, but in 1530 was obliged to relinquish the title of viceroy, receiving in exchange the island of Jamaica, an estate 25 leagues square in Veragua, a pension of 10,000 ducats and the titles of Duke of Veragua and Marquis of Jamaica. He was captain-general of Hispaniola 1542–51. Arrested in 1559 for having three wives, he was imprisoned for three years and then banished to Africa. Felipa, his daughter, married her cousin, Diego, who then became Duke of Veragua, but dying childless in 1518 the family of Columbus then became extinct in the male line. The present Duke of Veragua (b. 1857) traces his descent from Columbus through Diego, Cristobal, Diego's son, and Francesca, the daughter of Cristobal and sister of Diego Columbus, who died in 1578.

COLUMBUS, Ga., city and seat of Muscogee County, alt. 250 feet, 95 miles southwest of Atlanta, and on the Seaboard Air Line, the Southern and the Central of Georgia railroads, and on three federal highways. It is at the head of navigation on the Chattahoochee River, with steamboats running to Apalachicola, Fla. There is a city airport and one at Fort Benning. Columbus is the center of a rural territory producing beef and dairy cattle, hogs, cotton, peanuts, pecans, corn, sugarcane, and feed crops. Columbus has been called the «Lowell of the South.» It was a clothmaking center by 1840. The first cotton mill operated by electricity was here. Now its factories are operated mostly by hydroelectric power from the river which drops 360 feet in a 30-mile course. Bibb City, a textile town, is almost surrounded by part of Columbus. Soft coal and natural gas are cheap fuels. Factory products include hosiery, towels, sheeting, tire fabric and other textiles, farm machinery (especially cotton gins), packed meats, soft drinks, lumber, commercial furniture, brick, tile, foods (notably peanuts and pecans). The factory output in 1936 was valued at 60 million

dollars. Fort Benning, just south, has a United States infantry school. The city school system has fine trade and manual training courses. Columbus was settled in 1828. It has a commission-manager government (1922), and owns the waterworks. In the Civil War the city was an important supply depot of the Confederates. On 16 April 1865, the Federals captured it. Pop. (1910) 20,554; (1920) 31,125; (1930) 43,131; (1940) 53,280.

COLUMBUS, Ind., city and Bartholomew County seat; alt. 632 feet; on the East Fork of the White River; 41m. SE. of Indianapolis; on the Pennsylvania; and Cleveland, Cincinnati, Chicago and St. Louis railroads. It is in a diversified farming area; has a tannery; and manufactures of auto parts, Diesel engines, pulleys, leather goods, barrels, furniture, and garden tools. Pop. (1930) 9,935; (1940) 11,738.

COLUMBUS, Kans., city and Cherokee County seat; alt. 893 feet; in the SE. corner of the state; 50m. S. of Fort Scott; on the Missouri, Kansas and Texas; and St. Louis and San Francisco railroads. The city is in an agricultural and mining area producing wheat, corn, oats, flax, garden truck; coal, lead and zinc; and has manufactures of overalls, explosives, and butter. The town was organized and named in 1871, and incorporated in 1873. It occupied an earlier townsite known as «the center.» A medicinal spring found here attracted many settlers. Pop. (1940) 3,402.

COLUMBUS, Miss., city and Lowndes County seat; alt. 250 feet; on the Tombigbee River; 98m. NE. of Meridian, on the Columbus and Greenville; Mobile and Ohio; Southern; and Frisco railroads. It is the trade center of a farming and dairy region; ships cotton, hay, cattle and hardwood lumber; and has cotton and oil mills, woodworking plants, creameries, marbleworks and brick yards. A trading post, called Possum Town by the Indians, was established here in 1817. The first free school in the state, Franklin Academy, was founded here in 1821. Mississippi State College for Women was organized as Columbus Female Institute in 1847, and received its present name in 1920. The Confederate government maintained an arsenal here during the Civil War. Government is by mayor and council. Pop. (1930) 10,743; (1940) 13,645.

COLUMBUS, Nebr., seat of Platte County, alt. 1,441 feet, 92 miles northwest of Omaha on the Loup River, on the Union Pacific and Burlington railroads and two federal highways. Lake Babcock furnishes water for the Loup River Power District (co-operative) supplying cheap power. Meat packing, wooden-sole shoes, flour, canning are the main industries. It has a mayor and council. Pop. (1940) 7,632.

COLUMBUS, Ohio, capital of the state and seat of Franklin County, on a plateau 760 feet above sea-level at the junction of the Scioto and Olentangy rivers. Since 1913, when 100 lives were lost and much damage was done by flood, the Scioto channel has been made wider and safer. The city is almost in the exact geographical center of the state and owes much to being at the crossing of Ohio's main north-and-south and east-and-west transportation routes, and at the heart of Ohio's political and educational activities. Area, 39.5 square miles.

The surrounding country is largely agricultural with several active co-operative associations for the sale of wool and horses. Corn, wheat, soy beans, vegetables, orchard fruits, and grapes are grown. Dairying is a major farm industry, the region being rated among the most productive in the country; and the Ohio State Fair, held annually in Columbus ranks among the largest and best of its kind.

Metropolitan Columbus, as defined by the U.S. Census Bureau, has an area of 219.2 square miles and a population of more than 350,000. The growth of the actual city is shown by these census figures: (1830) 2,435; (1840) 6,048; (1850) 17,882; (1860) 18,554; (1870) 31,274; (1880) 51,647; (1890) 88,150; (1900) 125,560; (1920) 237,031; (1930) 290,564; (1940) 306,087. In 1930 five out of six were native-born whites, and about one in nine was Negro. The main immigrant strains up to 1914 were German, English, and Italian.

Columbus is served by the Pennsylvania, Baltimore and Ohio, New York Central, Norfolk and Western, and Chesapeake and Ohio railroads; by two major airlines at its municipal Port Columbus; and by several motorbus lines for passengers and freight. The city is on four major federal highways and on four state highways. The city's water works are municipally owned, and its engineers estimate that the huge Griggs and O'Shaughnessy dams on the Scioto River hold from five to six months' reserve. supply, even without rainfall. Their total capacity is 6,600,000,000 gallons, and 32,000,000 gallons are pumped and filtered as a daily average.

The capital is near rich supplies of coal, iron, natural gas, limestone, and clay, and has some trade in Ohio wool. No single industry is predominant, but there are large single factories making mining machinery, concrete-mixing machinery, and oilcloth. Of the industrial pay roll nearly 30 per cent is iron, steel and machinery; about 12 per cent foods; 10 per cent shoes and other leather goods; and another 10 per cent paper and printing. Unusual specialties manufactured here are caskets, glass, artificial teeth, motion picture screens, dumb-waiters, and tire covers. Columbus has several ceramic plants, is headquarters of the American Ceramics Society, and has a ceramics department in the State University.

The city is outstanding in scientific research. The Edward Orton Jr. Ceramic Foundation aids the Ohio potteries and manufactures pyrometric cones to find kiln temperatures. The Battelle Memorial Institute studies fuels and metallurgy for many industrial groups. The State University Bureau of Business Research investigates production and marketing problems. The National Farm Chemurgic Council has headquarters here. And the Chamber of Commerce has an active research department.

Columbus ranks high in literacy with 98.6 per cent of its population over 10 years of age able to read and write. There is an excellent public school system, and the city has fine parochial and private schools. Ohio State University from 1870 to 1878 was a federal land-grant agricultural and mechanical college. It has arts, engineering, commercial, journalism, technical, and professional schools, and a good graduate department. Among the state universities only California and Minnesota have a larger regular student enrolment. Capital University (1850) is

an outgrowth of the Evangelical Lutheran Theological Seminary (1830). Franklin University is a branch of the local Y.M.C.A. Otterbein College in Westerville, just north of Columbus, founded by the United Brethren in 1847, was one of the first American co-educational colleges. Among the Catholic institutions are: Josephinum College; St. Charles Borromeo College Seminary; St. Mary's of the Springs, for girls; and Aquinas High School.

Libraries in the city, including that of the State University, have about 1½ million volumes. The public library has an endowed music library. The state library pioneered in sending «traveling libraries» to different institutions.

Three daily and two Sunday newspapers are published in Columbus; the morning *Ohio State Journal* was founded in 1811. There are three commercial radio stations and WOSU, operated by Ohio State University, broadcasts educational and entertainment programs. The Gallery of Fine Arts cost $750,000 and has a good collection.

Columbus is the state's principal mobilization point for military forces, a position it has held since the Civil War era. Fort Hayes was established in the early 1860's as an arsenal, has been a military post since 1863, and is the headquarters of the Fifth Corps Area of the U.S. Army. It was called Columbus Barracks until 1923, when it was re-named in honor of President Hayes. Seven miles east of the city is the Columbus General Reserve Depot of the Army, a storage and distributing base for military supplies.

The city was well laid out in the early days with good planting and wide streets. Since 1920 a city planning commission has put zoning restrictions in force. High Street, a main business thoroughfare, is 100 feet wide. Broad Street, residential, is 120 feet. At the intersection of High and Broad is the State Capitol in a ten-acre square, built of local gray limestone. Inside are William H. Powell's painting of Perry's victory at Lake Erie and Thomas D. Jones' statuary group of the surrender of Vicksburg to Grant. At one entrance to the square is the H. A. McNeill memorial to McKinley. At the northwest corner are «Ohio's jewels,» statues of leaders in and after the Civil War—Grant, Sherman, Sheridan, Chase, Stanton, Garfield, and Hayes. There is a fine civic center. The city has unusually good department stores for its size. There are several co-operative retail stores and services, especially in areas where State University teachers and students reside.

Columbus has the advantage of being situated in a picturesque countryside, with many points of scenic beauty within easy driving distance; while the remains of the Mound Builders are of peculiar interest. In the near by Hocking Valley area may be found Cantwell's Cliffs, Conkle's Hollow, the Ashe and Old Man's caves, Serpent Mound, Black Hand Gorge and Buckeye Lake.

In 1797 Lucas Sullivant, a Virginia surveyor, settled on the west bank of the Scioto. A village there was called Franklinton. In 1803, when Ohio became a state, Franklinton became the seat of Franklin County. In 1812 the Ohio General Assembly, accepting an offer of four Franklinton settlers, established the permanent seat of state government on the east bank of the Scioto, opposite Franklinton, on high forest lands Congress had granted to Whig refugees from Canada and Nova Scotia. The name of Columbus was given because «to him we are primarily indebted in being able to offer the refugees a resting place.» In 1816 Columbus was incorporated as a borough and the Ohio Legislature first met here. It became the county seat in 1824 and a city in 1834. In the 1830's its growth was aided by the Columbus branch of the Ohio Canal and the National Road, and in 1850, by the first railroad from Cincinnati. The area of Franklinton was annexed in 1871.

Columbus is governed under a home-rule charter with a mayor and a seven-man council elected for four-year terms on a nonpartisan ballot, with preferential voting and referendum.

COLUMBUS, Texas, town and Colorado County seat, alt. 202 feet, on the Colorado River and the Southern Pacific Railroad, 85m. W. of Houston. It has gravel and concrete plants, and trades in cotton, rice, and other products of its agricultural environment. It has a commission government, with a city manager. The water system is city-owned. Pop. (1930) 2,054; (1940) 2,422.

COLUMBUS, Wis., city in Columbia County; alt. 842 feet; on the Chicago, Milwaukee, St. Paul and Pacific Railroad; 65m. NW. of Milwaukee. Situated in an agricultural area, its chief interests are in dairy products and the canning of peas. The city has a Carnegie library. Government is by mayor and council. The water, power, and light systems are municipally owned. Pop. (1940) 2,760.

COLUMBUS, Knights of. See KNIGHTS OF COLUMBUS.

COLUMBUS BARRACKS (now Fort Hayes). See COLUMBUS, OHIO.

COLUMELLA, Lucius Junius Moderatus, Roman practical writer on agriculture: b. Cadiz, Spain. He flourished about the middle of the 1st century, and wrote 12 books on gardening ('De Re Rustica'), one of which was a metrical combination of the Georgics of Virgil. He treats in this work of all the branches of agriculture. The earlier editions of this work contain also his treatise 'De Arboribus,' in one book. According to Pliny, Columella wrote a work on ancient sacrifices for obtaining the fruits of the earth, but this is lost. The *editio princeps,* printed in folio by Jenson at Venice, in 1472, and forming part of a collection of 'Rei Rusticæ Scriptores varii,' is very rare. The most complete edition is contained in the 'Scriptores Rei Rusticæ' of Schneider (1794–97). Consult Barbaret, 'De Columellæ Vita et Scriptis' (Nancy 1888); Becher, 'De Columellæ Vita et Scriptis' (Leipzig 1897).

COLUMN (Latin, *columna*), *in architecture,* a supporting pillar, usually round. In the earliest times the column was merely a tree-trunk, or its imitation in stone, used to support the roof. The original sense of the word is something that is high or rises in height. The root of the word survives in «Colonel» and the French «colline,» hill. The gods of nature were originally worshipped in certain places they were supposed to haunt, in the woods. The first temples were rude shelters in which the trunks of the trees of the forest, the «high things» were imitated. Hence, the first columns

were of wood, being merely trunks of trees, and nearly all the existing primitive columns are round. The parts of a complete column are its base, on which it rests; its body, called the shaft; and its head, called the capital. Columns are used to support the entablature of an order, which has also its proper division. In countries like Egypt, where timber fit for construction is scarce and stone abundant, the latter became the principal material for columns, and those of Egypt are remarkable for the beauty of their workmanship and the durability of their materials. The Egyptian columns were numerous, close, short and very large. They were generally without bases, and had a great variety of capitals, from a simple square block ornamented with hieroglyphics, or faces, to an elaborate composition of palm leaves, not unlike the Corinthian capital. The Greeks, for their columns, used marble of the finest kind, with which their country abounded; and other nations the stone or material of their country. The Greeks considered the column as an essential part of the architecture of their temples, and never used it as a mere decoration. In fact the primitive Greek temples were little else than roofed columns, thus showing clearly their origin.

The manner of constructing the columns of all the orders rests on similar principles. They are all divided into three primary parts or divisions, the base, the shaft and the capital, except the Doric order, which has no base. The lowest or thickest part of the shaft is used by architects as the universal scale or standard whence all the measures which regulate and determine heights and projections are taken; and this standard or scale must be understood before any architectural design can be commenced. The universal architectural scale is called a diameter, and is the diameter of the lowest or the largest part of the column; and, unlike the foot, inch or yard, is as various as the size of columns. By the diameter, of course, is meant that of the circle which forms the bottom of the column. Half of this diameter, or the length of the radius which forms the circle, is called a module, and is used as well as the diameter as a primary standard of mensuration by some writers upon architecture. These measures of length are subdivided as follows, namely: the diameter into 60 parts, and the module into 30 parts, called a minute. The Ionic column has a base peculiar to itself called the Attic, which, with that of the Corinthian order, is described under ARCHITECTURE.

The shafts of the orders differ in height and even in various examples of the same order. The capitals also are as various. Columns are either plain or fluted, and the flutes and manner of dividing them are different in the Doric and Corinthian orders. The Ionic flutes much resemble the Corinthian, and in many instances are exactly similar. Columns of all the orders taper gradually toward the top, but in the middle there is sometimes a slight swelling called an entasis. Roman architecture being derived from the Greek, Roman columns were either exactly similar to Greek or modifications of the latter. The principal modifications of the column made by the Romans were that form of the Ionic capital in which there were four pairs of diagonal volutes instead of two pairs of parallel ones, and that peculiar to the Composite order, in which the capital of the Corinthian column was combined with that of the diagonal or modern Ionic.

Columns are also often used for commemorative purposes as well as for architectural supports; and such are the Trajan and Antonine columns in Rome, and the Monument in London, erected in commemoration of the great conflagration of 1666, one of the loftiest, best constructed and most beautiful in existence. It is a Doric fluted column, 202 feet high from the bottom of the pedestal, which is ornamented with bas-reliefs of Charles II and his court giving protection to the fallen city, and various inscriptions, to the top of the vase of flames, by which it is surmounted.

COLUMN, *in military tactics,* a formation in which the units (soldiers, squads, sections, platoons, companies, troops, squadrons or battalions) are arranged from front to rear, or in general any formation with relatively great depth and a narrow front. Columns are found in different forms both in close and in extended order. In close order they may be divided into those that are purely drill formations and those that are march formations. The drill-formation columns may be open, when the distance between two successive units permits wheeling or turning into line, or close, when this is not possible. The units of which close columns are formed are companies in America, platoons in Great Britain. Double columns are used by several countries.

The marching formation of infantry in America is the column of squads, in which the change from line into column is made by the bodily turning of the squad, a body two men deep and four men wide, under the command of a corporal. Germany has a similar formation, but provides for a place for the officers, sergeants and other file-closers in the column, and not merely beside it. Great Britain and most other countries form the column from the line and vice-versa without a bodily shifting of distinct units. The change from line to column is accomplished in Great Britain by the command «Form-Fours!», on which odd numbers front and rear stand fast, and even numbers step to the rear and right. In France the minor units of the column of route are drawn up side by side; the section, under the command of a subaltern or adjutant, consists of four parallel squads in single file, which open up fan-wise in deploying into line. Column of twos or fours is the universal cavalry marching formation; column of sections is that of artillery.

In open order lines of small columns are used by infantry to gain ease of movement through brush and security from fire, especially on reverse slopes. They are also far easier to manœuvre than lines. In the American army, these columns are either squad columns, in single file, under a corporal, or platoon columns, in double file, under a sergeant or subaltern. In the French army, a section deploys into squad columns by the mere lateral separation of its squads. The French often arrange their squad columns in two echelons.

The principle of the column formation, that of echelonment in depth, is emphasized strongly by the French in actual fighting tactics. It enables one to secure that the reinforcement of

a depleted body of troops shall come from its own organization, and that as little confusion of command as possible shall result.

The term «column» is also used of the supply, ammunition, engineer and sanitary trains in the line of communication. These start from a rail-head or water-head, and turn over their supplies, etc., to the trains proper or take up wounded at refilling or distributing points.

Consult Balck, 'Tactics' (tr. Fort Leavenworth 1915); United States Small Arms Firing Manual; Infantry Drill Regulations; Cavalry Drill Regulations; Field Artillery Drill Regulations; Field Service Regulations. See also ARTILLERY; CAVALRY; INFANTRY; LINE; TACTICS.

COLUMN OF JULY, a monument erected in Paris in 1840, on the site of the old Bastile in honor of the citizens killed in the revolution of 1830. It is a shaft of bronze on a marble base, capped with a gilded statue of the Genius of Liberty. It is 154 feet high and 13 feet in diameter.

COLUMN OF SAINT MARK. See VENICE.

COLUMN OF TRAJAN, a monument erected in Rome in 114 A.D. in honor of the emperor. It is a Roman Doric column of white marble of 34 blocks, 23 composing the shaft, on which are carved representations of various scenes in Trajan's campaigns, containing 2,500 figures of men, each about two feet in height. The quadrilateral pedestal bears an inscription which can easily be read. It is 127½ feet high, exclusive of the statue of Saint Peter, which now stands on the apex of the column, having taken the place of the colossal figure of Trajan in 1587.

COLUMN VENDOME, vŏn-dōm, a monument erected in the Place Vendome, Paris, by Napoleon I, to commemorate the victories of the Grand Army over the Russians and Austrians in 1805. It is similar in design and ornamentation to the Column of Trajan, but is built of masonry encased in bronze taken from 1,200 captured guns, and capped by the statue of Napoleon. It is 142 feet high and 13 feet in diameter. It was overthrown in 1871 during the Commune but was restored in 1875.

COLUMNAR JOINTING, and **COLUMNAR BASALTS.** In lava flows (q.v.) and sills (q.v.) there is often manifested a peculiar structure consisting of five or six sided prisms or columns, separated by narrow cracks. These are usually at right angles to the cooling surface of the igneous mass. The cause is supposed to be contraction during cooling. Such columnar jointing is well displayed in the Giants Causeway (q.v.), at Fingals Cave (q.v.), along the Palisades of the Hudson (q.v.), in Yellowstone Park (q.v.) and at numerous other points.

COLURE, kō-lūr', one of two imaginary great circles of the celestial sphere passing through the celestial poles; one passing through the equinoctial point of Aries and Libra and the pole of the equator; and the other through the solstitial points of Cancer and Capricorn, and the poles both of the ecliptic and equator. For this reason the first is called the equinoctial, and the second the solstitial colure. The name, meaning «docked»» or «dock-tailed,» is now rarely used; it was originally applied because a portion of these circles is always concealed under the horizon.

COLUSA, Calif., city, Colusa County seat; on the Sacramento River; 71m. NW. of Sacramento; on the Southern Pacific Railroad; in a prune growing area. Pop. (1940) 2,285.

COLVILLE, SIR Edwin Henry, English general: b. 10 July 1852; d. 1907. He was educated at Eton and entered the grenadier service in 1870. He served in Egypt, the Sudan, Uganda and South Africa, where his failures led to his recall. He has published 'A Ride in Petticoats and Slippers' (1879); 'The Accursed Land'; 'History of the Sudan Campaign'; 'The Land of the Nile Springs'; 'The Work of the Ninth Division' (1901).

COLVILLE, Wash., town and seat of Stevens County, alt. 1,917 feet, 85 miles north of Spokane, on the Colville River and the Great Northern Railroad. Lumbering, agriculture, and mining make the town important. The Hudson's Bay Company established Fort Colville in 1825. Government is by mayor and council. Pop. (1940) 2,418.

COLVIN, SIR Sidney, English critic: b. Norwood, 18 June 1845; d. 11 May 1927. He was Slade professor of fine arts at Cambridge 1873–85 and keeper of prints and drawings at the British Museum 1884–1912. His writings include 'Children in Italian and English Design' (1872); 'Life of Walter Savage Landor' (1881); 'Life of Keats' (1887); 'A Florentine Picture-Chronicle' (1898); 'Early History of Engraving in England' (1905). He edited the Edinburgh edition of the works of Robert Louis Stevenson (1894–97), and also his letters. He was knighted in 1911.

COLVOCORESSES, George Partridge, American naval officer: b. Norwich, Vt., 3 April 1847. During the Civil War he served two years on the ships *Supply* and *Saratoga* and then entered the United States Naval Academy from which he was graduated in 1869. He was advanced through the several grades, becoming captain in 1905 and retiring, at his own request, as rear-admiral in 1907. He was present with Dewey at Manila Bay in 1898 and was advanced five numbers in grade «for eminent and conspicuous conduct» there. He served in nearly all the ports of the world, was instructor at the Naval Academy 1886–90 and again in 1893–96. In 1905–07 he was commandant of midshipmen and served at the War College and in command of the Key West Naval Station. Died 11 Sept. 1932.

COLWELL, Stephen, American lawyer and writer: b. Brooke County, Va., 25 March 1800; d. Philadelphia, 15 Jan. 1872. He was graduated at Jefferson College, studied law, was admitted to the bar and practised for some years in Pittsburgh. About 1830 he removed to Philadelphia, became an iron merchant and amassed a fortune. He early developed a fondness for the study of finance, political economy and social science, and frequently published the results of his studies on questions of current interest or debate. During the Civil War he aided the administration with pen, purse and voice, and was a liberal supporter of the work of the sanitary commission. He was appointed by the government one

of the commissioners to examine the internal revenue system and suggest improvements. He left his large and valuable library of works on political and social science to the University of Pennsylvania, where he also endowed a professorship of social science. Of his writings the following may be mentioned: 'Relative Position in Our Industry of Foreign Commerce, Domestic Production, and Internal Trade' (1850); 'New Themes for the Protestant Clergy' (1851); 'The South; . . . Effects of Disunion on Slavery' (1856); 'Ways and Means of Commercial Payment' (1858), his last and most important work.

COLY, a bird of the African family *Coliidæ*. See MOUSE-BIRD.

COLYMBIFORMES, an order of archaic birds, all aquatic, with webbed or lobed toes, the metatarsi extraordinarily flattened, and having great power in swimming and diving. There are two suborders: (1) *Colymbi,* the loons; and (2) *Podicipedes,* the grebes (q.v.). See ORNITHOLOGY.

COLZA OIL, COLESEED, or **RAPE OIL,** an oil, familiar from its use as an illuminating agent in the moderator and other lamps, expressed from the seeds of several plants of the cabbage and turnip genus, the name being originally "kolzaad" (Dutch), that is kail- or cabbage-seed. It is yellowish brown, has a specific gravity of .92, and little or no smell, and dissolves in hot alcohol and in ether. It becomes thick and solid only at very low temperatures; when heated it volatilizes, but not completely, undergoing partial decomposition. It is purified for use by continued agitation with sulphuric acid, which destroys mucilaginous matter from the seed, and washing with water to remove all trace of the acid. The oil is used in Great Britain and on the Continent in soap-making, tanning, fulling of cloth, lubricating machinery and for burning. For the last it is so well adapted that it was specially recommended for lighthouse purposes. It is brilliant and steady, is managed with very little attention and is cheap. In these respects it is said to be superior to spermaceti.

COMA, *in medicine,* a state of complete or almost complete unconsciousness, resulting from various diseases, as apoplexy; from poisons, as opium, uræmia, diabetes, alcohol; from accident or injury to the brain; or from excessive cold. In cases of coma the pulse is usually slow and soft, but sometimes quick, the breathing is rarely stertorous, the pupils of the eyes are commonly more or less dilated and the face is often swollen and livid. The patient is either altogether unconscious and incapable of replying to any question, or he makes incoherent and rambling statements. Stimulating agencies and blistering are sometimes used in the treatment of comatose cases, but generally the disease or injury producing the condition determines the remedy.

COMA BERENICES, bĕr-ĕ-nī'sēz ("the Hair of Berenice"), a northern constellation, the name of which is due to the flattery of Alexandrine astronomers, who professed to see in the new constellation a lock of the beautiful hair of Berenice, wife of Ptolemy Euergetes. Callimachus in Greek and Catullus in Latin wrote poems descriptive of the apotheosis of the curl. Ptolemy did not introduce it into the Almagest as a distinct constellation, but called it *Plokamos* (Gr., "hair," or "curl"). Tycho Brahe restored it as a distinct constellation in his catalogue of 1602. It is formed of rather faint stars, none being brighter than the fourth magnitude. Baily, in the "B. A. C." in 1845, attached the first three letters of the Greek alphabet to three of the brighter stars. The constellation is surrounded by Ursa Major, Canes Venatici, Boötes, Virgo and Leo.

COMACCHIO, kō-mä-chē'o (ancient COMACTIUM), Italy, town in the province of Ferrara, in Emilia, about 20 miles north of Ravenna and 30 miles southeast of the city of Ferrara. The town is built on 13 islands which are connected by bridges. The chief industries are fishing and manufacturing salt.

COMAN, Katherine, American teacher: b. Newark, Ohio, 23 Nov. 1857; d. Wellesley, Mass., 11 Jan. 1915. She was graduated with the degree of Ph.B. at the University of Michigan 1880, and at once joined the faculty of Wellesley College, remaining there until her death. She was professor of economics there from 1900 to 1914. She went abroad in 1913–14, and made a special study of social insurance, as worked out in England, Spain, Belgium and the Scandinavian countries. This study, which was to have included France, Germany and other countries of Europe, was interrupted by the illness which brought her home to die. She published 'Growth of the English Nation' (1895); 'History of England' (1899); 'History of England for Beginners' (1901), and in collaboration with her colleague Katherine Lee Bates, 'English History Told by English Poets' (1902); 'Industrial History of the United States' (1905); and 'Economic Beginnings of the Far West' (2 vols., 1911).

COMANA, kŏ-mā'na. (1) An ancient city of Cappadocia, supposed to be the modern Elbostan, on the river Sarus, celebrated in antiquity for its temple of Artemis Tauropolis, and for the great devotion of its inhabitants to the worship of that goddess. Over 6,000 persons were engaged in the service of the temple. The city was governed by the high priest, who was always a member of the reigning family, and took rank next to the king. (2) A city of Pontus, now Tokat, on the river Iris, and almost as famous for its devotion to Artemis as the other city of the same name. There is evidence to show that this worship to Artemis or Ma, as the goddess was generally called in both the cities of Comana, was originally that given to the Moon goddess; and it had some suggestive resemblances to that of Isis in Egypt.

COMANCHE, kō-măn'chē, **CAMANCHE, CHOUMAN, COMANDE.** Their own name is Nüm, "people"; the Sioux gave them one which the French turned into Padouca, a powerful and ferocious tribe of the widely distributed Shoshonean stock, speaking the same language as the Shoshones of Wyoming, and traditionally their neighbors. When first made known to the whites by the French under Dutisné, they were located in eastern Colorado. They had already obtained horses from the Spaniards and become nomads and expert horsemen, and horse-breeders, for the French bought

horses from them. In 1724 another French expedition made a treaty with them. They seem shortly after to have been pushed southward by the Sioux, and we find them later roving the plains of northwestern Texas, making plundering raids from Colorado through Texas, deep into Mexico, and westward to Santa Fé. They lived in skin wigwams, with few or no fixed villages except near the Spaniards, and were in eight bands, with a very loose organization. They probably numbered 5,000 warriors, and 25,000 in all, at their best estate. One village near the Spaniards had 800 warriors, and over 4,000 in all. They were at constant war, both with the Spaniards and the other Indian tribes, and in 1783 engaged in a wholesale war with the former; but Anza inflicted a crushing defeat on them, killing 30 of their chiefs, and there was peace for a time. In 1816 they are said to have lost 4,000 of their number by an epidemic of smallpox; but they were still estimated at 9,000; and in 1847 at 10,000 or 12,000, one-fifth warriors. They recruited their numbers by kidnapping and adopting Mexican children, boys or girls. For all the years of immigration into those regions, down to 1875, they were the bloody and relentless scourge of the white settlers, and furnished a good part of the Indian horrors of the Southwest. They were once placed on a reservation in Texas, but were driven off. In 1868 the bulk of them agreed to go on a reservation in western Oklahoma; but the Quahada or Staked Plain band refused, and kept up their murderous forays. They were sharply punished by Colonel McKenzie at McClellan's Creek in 1872, in which year they were estimated at 3,218 on the reservation, with 1,000 more in roving bands. The last of these surrendered in 1875. In 1901 their reservation in Oklahoma was thrown open to settlement. At present they number about 2,000. Consult Lehmann, H., 'Nine Years Among the Indians' (1927).

COMANCHE, Texas, city and Comanche County seat; alt. 1,358 feet; 112m. SW. of Fort Worth; on the Santa Fe Railroad. It is in a diversified farming area growing peanuts, pecans, fruit and grain, and having natural resources of oil and gas. It has a cannery, pecan and peanut shelling plants, cotton gins, flour mill, poultry dressing plant, and cheese factory. It was settled about 1857 and was an early supply point for cattlemen. Pop. (1940) 3,209.

COMANCHEAN. See CRETACEOUS.

COMAYAGUA, kō-mä-yä'gwä, or **VALLADOLID LA NUEVA,** Honduras, C. A., a town, capital of the department of the same name, situated on the southern border of the plain of Comayagua, on the Humuya River, 220 miles east of Guatemala. It is the seat of a bishopric, has a large and handsome cathedral, a richly endowed hospital, several convents and a college. It was founded by Alonzo Caceres in 1540, and up to 1827 was a thriving place, with about 18,000 inhabitants. In that year, however, it was burned by the monarchical faction of Guatemala, and has never recovered. Pop. 6,412.

COMB (A.S. *camb*), an instrument to separate and adjust the hair, too well known to need description. We have no certain authority that either the Greek or the Etruscan women applied this useful article regularly to their hair in the operations of the toilet, although it was used by the Greek women, at least, to arrange their hair. The combs used by the Greeks were of boxwood, and had teeth on both sides, while those used by the Egyptians had teeth only on one side. The Romans also had combs of boxwood, and at a later time probably of ivory and other materials. In the work of Guasco Della Ornatrici there are several representatives of ancient Roman combs. One of them is a long one of box, of which the handle is overlaid with ivory, and appears to have been ornamented with a small meander in gold. It has two rows of fine teeth, delicately wrought and well proportioned. Modern combs are generally made of tortoise shell, ivory, horn, wood, bone, metal, india rubber and celluloid. Machinery has been perfected for their production. In making combs the material is first cut to the form which the comb is to have, and the teeth are then made all at once by means of circular saws mounted on the same axle and placed at a suitable distance from one another. Large combs in horn or shell, with wide teeth, are sometimes made with a punch, which cuts in the piece the teeth of two combs by the same operation. The teeth are afterward finished with the file. Combs made of vulcanized india-rubber, which are now so common, are made by pressing the caoutchouc while soft into molds, and then bringing them to the desired degree of hardness by the process of vulcanization. Canova and other modern sculptors have made great use of the comb, placed in the heads of their women, to which they add much grace and elegance.

COMB, the wax cavities in which bees lodge their honey. The comb of a bee is composed of hexagonal cells, of which there are two tiers, the cells of which are placed end to end, so that the three plates of wax, which serve as the bottom of the cell in the one tier, constitute also that of the corresponding one in the other. The mathematical problem in "maxima and minima," how to construct the greatest number of cells within the smallest possible room, and with the least expenditure of material, is solved.

COMBA, kŏm'bä, **Emilio,** Italian author: b. San Germano Chisone 1839. He became a professor at the Istituto Valdese at Florence; there he founded in 1873 the review entitled *Rivista Cristiana,* devoted to the discussion of religious problems and topics. He is the historian of the religious reform in Italy. His works include 'Introduzione alla storia della riforma in Italia' (1881); 'I nostri protestanti' (1897); 'Storia dei Valdesi' (latest ed., 1901; Eng. trans., 1889). D. Switzerland, 3 Sept. 1904.

COMBACONUM, Madras, British India, town in the district of Tanjore, 194 miles from Madras. It is regarded by the Hindus as a place of peculiar sanctity, and is inhabited largely by the Brahmans. It contains numerous pagodas and tanks with water, supposed to come from the Ganges River. One of the oldest places in southern India, it is one of the strongholds of Brahmanism and Brahmanical culture. Pop. about 64,000.

COMBASOU, the trade name of an African weaver-bird (*Hypochæra chalybeata*), kept in aviaries for its pretty plumage and manner. The male is black with a bluish gloss, bill white and legs pink; the female is brownish.

COMBAT, in its general sense signifies a fight. The noun form is derived from the verb and the latter from the French of the same form. Owing to the prevalence of single combats in Normandy and England in early Norman times, the word combat, in England, where it was not altogether at home, came to be restricted in sense generally to a fight between two individuals or between two parties, each chosen to uphold the honor of its own party or faction. Trial by combat and the ordinary single combat encounter have both the same origin, which goes back to the dim ages long before formal history began. Originally single combat was frequently made use of to adjudge the guilt or innocence of the contending parties, and it was itself the same in import and origin as the trial by combat in all its various forms. The witch was tried by water, which she was popularly supposed to hate. In India women accused of unfaithfulness to marriage vows were subject to trial by fire to test their innocence or guilt. The single combat, early in the organization of society, came to be a union of two social inclinations, that of the tendency of two disputants to fight out their quarrel, and that of the potent influence of magic in which all primitive tribes believed and which was supposed to help the more powerful contendant. Later on this magic idea of the barbarian races and the savages gradually surrounded itself with a moral atmosphere, the result of attributing the magic itself to the influence of the gods and their interference in behalf of one of the contendants, generally the one in the right. Later the idea of a divine guardianship of every human being came to lend a still more pronounced moral atmosphere to the single combat fought to decide a question of right or wrong. Gradually, however, this moral idea lost ground in ordinary single combat encounters, as the age of chivalry advanced, without a weakening of influence in its own particular sphere of trial by ordeal, into the service of which the trial by single combat still continued frequently to be pressed to the end of the age of chivalry. Very ancient usage was evidenced by Goliath (1 Sam. xvii), and by Ajax in the 'Iliad,' and by many of the characters in the mythologies of various nations. Among the Scottish clans the combat was sometimes between individuals; but just as often between a certain picked number on each side. Then again not infrequently one clan defied another to combat. The Norse practice of principals going alone to a small holm or island, to be free from disturbance while settling their quarrels by strength and skill, gave rise to the Saxon term *Holm-Gang.* In the days of chivalry the single combat received the strong support of law and custom, and was resorted to both in civil and in criminal cases. The accuser or plaintiff swore to the truth of his tale, the other gave him the lie, a gage of battle was thrown down and taken up, and they fought it out under rules before an assembly, the supposition being that God would give victory to the right. The barbarous practice survives in European countries, without its excuse of superstition, in the modern duel, which is legally prohibited in the United States. In England it was still a legal method of trial well into the 19th century, but was abolished by statute 59 George III, cap. 48.

COMBAT TRAINS. See AMMUNITION.

COMBE, kōm or koom, **Andrew,** Scottish physiologist: b. Edinburgh, 27 Oct. 1797; d. there, 9 Aug. 1847. He was educated for the medical profession, and in 1822 he commenced practice at Edinburgh, and had considerable success. In 1838 he was appointed one of the physicians extraordinary to the queen in Scotland. His chief works are 'Observations on Mental Derangement' (1831); 'Principles of Physiology' (1834); 'Physiology of Digestion' (1836); 'A Treatise on the Physiological and Moral Management of Infancy' (1840). Like his brother George (q.v.), he was a zealous phrenologist.

COMBE, George, Scottish phrenologist: b. Edinburgh, 21 Oct. 1788; d. Moore Park, Surrey, 14 Aug. 1858. He was a brother of Andrew Combe (q.v.), was bred to the law, and in 1812 admitted a member of the Society of Writers to the Signet. He was the first to introduce the doctrines of phrenology into Great Britain; and visited Germany and America, lecturing on his favorite science. He was also a zealous promoter of the cause of popular education and social progress; and was among the first to advocate compulsory education and the establishment of a board of health. He was a frequent and important contributor to the *Phrenological Journal* and he wrote for other publications, and in his own works, on education, theology, politics, economics and other subjects and matters of general interest. He had a way of presenting his subject that made him an immensely popular writer. Besides the 'Constitution of Man' (1828), which has had an enormous circulation, he was the author of 'A System of Phrenology' (1825); 'Lectures on Popular Education' (1833); 'Moral Philosophy' (1840); 'The Life and Correspondence of Dr. Andrew Combe' (1850); 'Principles of Criminal Legislation and Prison Discipline Investigated' (1854); 'Relation Between Science and Religion' (1857).

COMBE, William, English writer: b. Bristol 1741; d. Lambeth, 19 June 1823. His 'Tour of Dr. Syntax in Search of the Picturesque' (1812) was once very popular. Other works by him are 'The Diaboliad,' a poem (1776); 'The Devil Upon Two Sticks in England' (1790). After 43 years within the rules of a debtor's prison, and previous vicissitudes of fortune from army officer to cook, he died in Lambeth.

COMBERMERE, kŭm'bêr-mêr, **Sir Stapleton Cotton,** VISCOUNT, English general: b. Denbighshire, 17 Nov. 1773; d. Clifton, 21 Feb. 1865. He entered the army in 1790, served in Flanders and India, and with the rank of major-general accompanied the Duke of Wellington to the Peninsula in 1808. In 1809 he succeeded to the family baronetcy. At Salamanca, in 1812, he headed the brilliant cavalry charge which greatly contributed to the decisiveness of that victory, and was subsequently present at the battles of the Pyrenees,

Orthez and Toulouse. Shortly after the last battle he was raised to the peerage with the title of Baron Combermere. From 1817 to 1820 he was governor of Barbados; 1822–25 commander-in-chief of the army in Ireland, and in 1825 was sent to India as commander-in-chief of the forces there, to put down the usurper Doorjun Sal. After a siege of less than two months, Bhurtpore, the chief city of Doorjun, was taken by storm on 6 Feb. 1826, for which Combermere was raised to the rank of viscount. The remainder of his life was passed in England. In 1852 he was appointed constable of the Tower; and in 1855 made a field-marshal.

COMBES, koomb, **Justin Louis Emile,** French statesman; b. Roquecourbe, Tarn, France, 6 Sept. 1835; d. 24 May 1921. He was educated in a Roman Catholic seminary for the priesthood, but subsequently studied medicine, and began practice in Pons, where he filled various posts of responsibility, such as those of mayor and county councillor. In 1885 he was elected to the Senate, of which he was vice-president 1893–94, becoming Minister of Public Instruction in 1895. He was active in the reorganization of primary and secondary education. In June 1902 he succeeded Waldeck-Rousseau as President du Conseil des Ministres. In this capacity he enforced the Association Act, abolishing liberty of teaching in France and aimed at the clergy. The law against the religious orders was enforced with great severity, and over 500 teaching, preaching and commercial orders were suppressed under the Combes régime and their members underwent great hardships. His opponents claimed that this was done with needless severity. It caused widespread disturbances throughout the country. On his becoming Prime Minister, M. Combes announced his intention to reduce the period of military service to two years, and to establish a general income tax. Steps were also taken during his ministry which were to lead later to the separation of Church and State. In spite of the fact that M. Combes was upheld by the Chamber in all his acts, he resigned in 1905 because of the intense bitterness which these acts aroused among the Conservatives. M. Combes was a latter-day Voltaire, with all of his master's hatred of clericalism in all its forms. To him the Catholic Church appeared as the sworn enemy of modern life and culture and particularly of the Republic of France. Personally he was what is called in France an "austere Republican," a man simple in his private life and rigid in his adherence to Republican principles.

COMBINATION, *in mathematics,* the selection, from a given set of objects, of a stated number without regard to their arrangement. Each combination can, by varying the arrangement of the constituent objects, be made to give rise to several permutations. Thus of the four letters, *a, b, c, d,* four combinations, three at a time, are possible; namely, *a b c, a b d, a c d, b c d.* Each of these combinations, however, produces six permutations, according to the order of the letters. For example, the combination *a b c* yields the six permutations *a b c, a c b, b c a, b a c, c a b, c b a.* Thus, of the four letters, *a, b, c, d,* the number of permutations three at a time is 24. It is easy to prove that the number of permutations of n objects two at a time is $n\ (n-1)$; three at a time $n\ (n-1)\ (n-2)$; four at a time $n\ (n-1)\ (n-2)\ (n-3)$; and so on, the number when r at a time are taken being $n\ (n-1)\ (n-2)\ldots(n-r+1)$. The number of permutations of n things n at a time is therefore $n\ (n-1)\ (n-2)\ldots 4, 3, 2, 1$, a product usually represented by $\lfloor n$ or $n!$, and read as "factorial n." The theory of permutations and combinations is of very great importance in higher mathematics, and may be studied in any textbook of algebra, such as those by Chrystal, Todhunter and Smith.

COMBINATION, Industrial, *in law,* a union of individuals, companies or corporations formed for the purpose of accomplishing a particular object or purpose. In the United States a combination is not unlawful in itself, though it becomes so if it seeks to obtain its ends in an unlawful manner or by unlawful acts. Combinations may be divided into two general classes, those formed by employees or "labor," and those formed by employers or "capital." Combinations formed by employees, or labor, generally bear the designation of unions. The purpose of a union is to better the condition of its members in relation to the work in which they are engaged, by securing higher wages, less working hours, different methods of doing the work and similar changes. A union generally tries to enforce its demands by striking, or threatening to strike. A strike is a combination effected by employees whereby at a prearranged time they all stop working unless their demands are granted. A strike is usually organized through a union.

A boycott is a combination to cause a loss to a particular person by restraining others from doing business with that person. It is often so conducted that the person is affected socially as well as in his business. When a boycott has been declared against a person, any one having either business or social relations with that person is also boycotted.

When the objects of such combinations are effected in a peaceful and lawful manner there is no legal means by which they can be interfered with; but it generally happens that when a number of working-people strike there is a breach of contract, or a conspiracy, in which case there is a legal redress. The usual action is for the injured party to proceed in equity and ask for an injunction restraining the former employees from committing certain acts. Sometimes damages are asked for, and it makes no difference what the status is when the cause is heard, as damages can be recovered for acts committed during a strike, although the strike may have ended long before the demand for damages.

Combinations formed by employers, or capital, are usually known as trusts. Trusts are generally formed with the object of regulating the supply or price of a product, or both, or for the purpose of reducing expenses or competition.

It has been found very difficult to frame a law which will be effective against all the different arrangements under which a trust can do business. The State courts have no jurisdiction outside the limits of the State to which they

belong, and it is very seldom that a trust would be formed whose business would be confined to any one State. The Federal government has passed several anti-trust laws, and up to the present time the most effective way of dealing with this class of combinations is by laws passed under the clause in the Federal Constitution (Art. I, § 8, cl. 3), which provides that Congress shall have power "to regulate commerce with foreign nations, and among the several States, and with the Indian tribes." See BOYCOTT; STRIKES AND LOCKOUTS. Consult Jenks, T., 'Trusts and Industrial Combinations'; Watkins, M. W., 'Industrial Combinations and Public Policy' (1927).

COMBINATIONS AND PERMUTATIONS. Combinations and permutations deal with the arrangement and grouping of objects. They arose out of problems such as these: "How many numbers can be thrown with two dice?" "How many striped flags can be made with three colors?" "How many whist hands of 13 cards each can be dealt from a pack of 52 cards, the cards being put back and shuffled after each deal?" Although games of chance furnished most of the problems in the beginning, the modern aspect of the subject finds applications in statistics, probabilities and the theories of numbers, finite group, and algebraic forms. Aside from isolated references to single questions in the works of the Greek mathematicians, the earliest attempt at organized treatment of combinations and permutations occurs in the treatise of the Hindu astronomer Bhaskara Acharya in the 12th century. The subject received no further attention until the time of Cardan (1501–76) and another century elapsed before Pascal (1623–62) succeeded in building it into a science, as yet, however, in its infancy. Hindenburg (1741–1808) is regarded as the founder of the modern theory, but his school, known as the "combinatory school" held aloof from the rest of mathematics. Since then the researches of Jacobi, De Morgan, Sylvester, Cayley, Franklin, Mathews and MacMahon have shown its use in the general theories of arithmetic and algebra. We shall take up only elementary combinations and permutations; for a complete treatment of combinatory analysis consult MacMahon, 'Combinatory Analysis' (1915), and Netto, 'Kombinatorik' (1901).

Permutations.—A permutation of n elements taken r at a time is a linear arrangement, as in a row, of r of those n things with regard to the order in which they may be placed; e.g., $a\ b\ c$ and $a\ c\ b$ are permutations of a, b, and c. This name was given by Jacob Bernoulli ('Ars conjectandi' 1713). The number of permutations will be denoted by $P_{n,\ r}$, n being the total number of elements and r the number in a group; the notation $(n\ r)$ or $(n)_r$ is often used. To find $P_{n,\ r}$, observe that the first one of the r objects may be selected in n ways and for each selection there are $n-1$ things left from which to choose the second object; both may thus be chosen in $n(n-1)$ ways. By continuing the argument we find:

$$P_{n,\ r} = n(n-1)\ (n-2) \ldots .\ (n-[r-1])$$

there being r factors. The following table gives numerical values of $P_{n,\ r}$ from $n=4$ to 10 and $r=2$ to 10. From the table $P_{8,\ 5}=6720$ and is found under $n=8$ and opposite $r=5$. $P_{3,\ 3}=P_{3,\ 2}=6$; $P_{2,\ 2}=P_{2,\ 1}=2$. S_p will be explained later.

VALUES OF $P_{n,r}$ AND S_p

r \ n	10	9	8	7	6	5	4
2.....	90	72	56	42	30	20	12
3.....	720	504	336	210	120	60	24
4.....	5,040	3,024	1,680	840	360	120	24
5.....	30,240	15,120	6,720	2,520	720	120	...
6.....	151,200	60,480	20,160	5,040	720	...	...
7.....	604,800	181,440	40,320	5,040	...	...	...
8.....	1,814,400	362,880	40,320	...	...	...	...
9.....	3,628,800	362,880	...	...	...	...	...
10.....	3,628,800	...	...	...	...	...	...
S_p.....	9,864,100	986,409	109,600	13,699	1,956	325	64

When $r=n$

$$P_{n,\ n} = n(n-1)\ (n-2) \ldots .\ 2 \text{ to } n \text{ factors.}$$

This product of the integers from 1 to n is represented by

$$n! = n(n-1) \ldots 2$$

and is read *factorial* n; it is due to Kramp (*Eléments d'arithmétique universelle,* 1808). The number of r permutations is therefore written

$$P_{n,\ r} = \frac{n!}{(n-r)!}$$

Now when $r=n$, $P_{n,\ n}=n!$ hence $(n-n)!$ or $0!$ must equal unity. That is, if Kramp's notation is to be carried out consistently we must regard $0!$ as a symbol for unity although according to the strict meaning of $n!$ factorial 1 is 1 and factorial 0 is 0. But as both 1! and 0! must be taken as unity

$$P_{n,\ n} = P_{n,\ n-1}\ ;$$

the table shows this to be so.

When n is large as in the theory of probabilities, $n!$ can be computed from the series due to Laplace (*Théorie des probabilités*):

$$n! = n^n\ e^{-n}\sqrt{2\pi n}\left(1 + \frac{1}{12n} + \frac{1}{288n^2} + \ldots\right)$$

which as n increases indefinitely approaches

$$n! = n^n\ e^{-n}\ \sqrt{2\pi n},\ approx.;$$

this is Stirling's formula (*Methodus Differentialis,* 1730). For example, when $n=10$ this approximation gives 3,598,700 which differs from the correct value in the table by 0.83 per cent. For $n=20$ the error is less than one-half per cent. The number of permutations often runs astonishingly high; the number of whist hands in the problem stated at the beginning of this article is $P_{52,\ 13}=635{,}013{,}559{,}600$ so that the probability of a player getting the same hand twice in a lifetime is remote to say the least.

The sum of the permutations of n things successively one at a time, two at a time, and so on up to all at a time is

$$\sum_{m=1}^{m=n} P_{n,\ m} = S_p,\ say,$$

where Sp is given in the last row of the table.

Since

$$P_{n,\ m} = \frac{n!}{(n-m)!}\ and\ P_{n,n} = P_{n,\ n-1}$$

$$S_p = n!\left(1 + \frac{1}{1!} + \frac{1}{2!} + \ldots + \frac{1}{(n-1)!}\right)$$

When n is large the parenthesis approaches the

base of Naperian logarithms $e=2.7183\ldots$

$$S_p=\frac{n!}{e}=n^n\ e^{-n-1}\sqrt{2\pi n}\ \ approx.$$

The following results are useful: consult Chrystal, 'Text Book of Algebra'; Hall and Knight, 'Advanced Algebra.'

1. The number of permutations of n things of which a are alike, b are alike and the rest different is $n!/a!b!c!$

2. The number of permutations of n things in a circle is $(n-1)!/2$ if the clockwise or anti-clockwise order is indifferent. Thus 8 people may be seated around a table in 2520 ways.

3. The number of r permutations of n things when each thing may be repeated up to r times is n^r. With a night signal of 4 colored lights each of which may occupy 3 positions, $3^4=81$ signals may be made.

Combinations.— In a combination the order of elements in a group is indifferent, i.e., $a\ b\ c$ and $a\ c\ b$ are not different combinations. The word is due to Pascal ('Usage du triangle arithmétique,' 1665). The formula for combinations follows from that of permutations, for $P_{n,r}$ consists of groups of r things at a time and each group of r exists in $r!$ arrangements; hence if the arrangements within a group are not counted

$$C_{n,r}=\frac{P_{n,r}}{r!}=\frac{n!}{r!(n-r)!}=\frac{n(n-1)\ldots(n-r+1)}{r!}$$

But each time that a group of r is formed a group of $n-r$ is left

$$\therefore\ C_{n,r}=C_{n,n-r}$$

which shortens the computation when $r>n/2$

VALUES OF $C_{n,r}$ AND S_c

r \ n	10	9	8	7	6	5	4
2	45	36	28	21	15	10	6
3	120	84	56	35	20	10	4
4	210	126	70	35	15	5	1
5	252	126	56	21	6	1	....
6	210	84	28	7	1	....	....
7	120	36	8	1	....	....	....
8	45	9	1	....	....	....	....
9	10	1	....	....	....	....	....
10	1	....	....	....	....	....	....
S_c	1,023	511	255	127	63	31	15

The coefficients of the binomial expansion are combinations:

$$(a+b)^n=a^n+C_{n,1}a^{n-1}b+\ldots+C_{n,n}b^n$$

when $a=1=b$

$$2^n-1=C_{n,1}+C_{n,2}+\ldots+C_{n,n}=S_c,\ say,$$

which is sometimes called the *total* number of combinations and is the total number of ways in which a selection can be made by taking some or all of n things. Now each element may be taken or left and for each of these two ways of dealing with it each remaining element may be taken or left; therefore the number of ways of selecting or leaving the n elements is 2^n. But this includes the one case in which all are left; thus $S_c=2^n-1$ as above. As an interesting illustration consider the Baudot Signal Code which is used by the Western Union Telegraph Company for the simultaneous transmission of messages. Each character (letter of the alphabet, etc.) consists of some or all of five crosses occupying five blank spaces represented by dashes; e.g., $a=+\ +\ -\ -\ -$, $b=+\ -\ -\ +\ +$, $c=-\ +\ +\ +\ -$. Five dashes mean that no crosses are used, i.e., the case where all the elements are left. The number of signals possible is consequently $2^5-1=31$.

R. F. DEIMEL,
Professor of Mechanical Engineering, Stevens Institute of Technology.

COMBUSTION is chemically the rapid oxidation of a substance with the evolution of light and heat. It is generally accompanied by flame and the production of carbon dioxide, carbon monoxide and the vapor of water. The substances which are consumed are popularly termed combustibles. Chemically, the substances oxidized are the carbon and hydrogen components of the combustibles. The heat in combustion is a result of the chemical changes which take place during oxidation. The light is emitted by incandescent particles of carbon in the flame. The temperature to which any particular substance must be raised in order that it shall take fire is called the "ignition point" of that substance. Ignition points vary with the different combustibles. They may even be below the temperatures which ordinarily prevail. In such case the substance will burst into flame when that temperature is reached, and this phenomenon is called "spontaneous combustion." Some kinds of vegetable and animal oils when spread out thinly, as on a rag, may oxidize so rapidly as to become very hot, and if in a confined place will eventually take fire spontaneously.

In combustion two classes of combustibles are recognized: (1) Those which in the process generate heat sufficient to continue the combustion until the whole of the combustible is consumed; (2) those in which the combustion can only be kept continuous by the constant application of external heat. When the processes of combustion take place instantaneously the combustion is called an explosion. Acetylene may be mentioned as an example in this connection. It has a tendency, especially when under pressure, to decompose, with the evolution of so great a degree of heat as to expand enormously and result in an explosion. The economic use made of combustion is chiefly for the generation of power, but also in cooking and the heating of houses and the production of all artificial lights but electric light. The combustibles utilized in this way are called fuels. See EXPLOSIVES, FUELS; FURNACE; GAS; HEAT; LIGHT; OXYGEN; PHLOGISTON. Consult Haslam and Russell, 'Fuels and their Composition' (1926).

COMBUSTION, Spontaneous, the ignition of bodies by the internal development of heat without the application of an external flame. It not infrequently takes place among heaps of rags, soot, paper, woolens, cotton and other substances strongly lubricated with oil, when, if the oil is freshly made, it is very ready to combine with the oxygen of the atmosphere and give out carbon and hydrogen. The heat thus developed, diffusing itself through a mass of highly inflammable substances, will in certain circumstances be sufficient to set them on fire. A remarkable instance of spontaneous combustion among hemp was afforded in June 1861, being the cause of the terrible conflagration in Tooley street, London. Bituminous coal, piled

up in heaps, is apt to ignite by the decomposition of the sulphuret of iron which it contains. In ships laden with coal impregnated with sulphur and iron in the form of bi-sulphuret of iron (pyrites), decomposition of this substance is sometimes occasioned by the access of moisture, and heat is evolved to such a degree as to cause the combustion of the coal, especially if air is admitted freely. Water poured upon the burning material only adds to the intensity of the action. Charcoal and green hay are liable to spontaneous combustion. A somewhat unusual case of spontaneous combustion occurred in 1916, when an explosion in a flour mill was found to be due to accidental spark ignition of an intimate mixture of flour dust and air. Legends and tales exist of spontaneous combustion of human bodies; but no authenticated case has been recorded, and it is regarded as impossible.

COMBUSTION, Velocity of. It can be shown by direct experiment that the burning of a grain of powder in a fire-arm is progressive, and that the size of the grain exerts a great influence on the velocity of the projectile. For instance if one piece of the press cake were placed in a small mortar and fired, little or no motion would be given to the projectile. If this piece be divided into seven or eight parts, the projectile will be thrown a short distance; and by increasing the number of parts or grains, so will the effect of the powder on the projectile also increase. The progressive burning of powder is further confirmed by the fact that burning grains are sometimes projected from the gun with sufficient force to perforate screens of paper and wood at considerable distance. It is even found that they are set on fire in the gun and afterward extinguished in the air before they are completely consumed. The velocity of combustion of powder varies with the purity, proportions, triturative, density and condition of the ingredients, also with the pressure under which the powder is burned. By varying the proportions and increasing the sulphur there is a tendency to make a more violent explosion and a more quickly kindling mixture. A general formula may be deduced to show the amount of gas developed and the quantity of powder burned at any instant of the combustion of a grain or charge of powder. For this purpose take a spherical grain of powder and consider it inflamed over its entire surface. Let t represent the time of burning, from the instant of ignition to the moment under consideration; R, the radius of the grain. Since the combustion of the grain passes over the radius R in the time t, the velocity of combustion is equal $\frac{R}{t}$ and for the time, t, it will pass over the space $t\,\frac{R}{t}$ or $R\,\frac{t}{t'}$; the radius of the decreasing sphere will therefore be $R\ (1-\frac{t}{t'})$. The volume of the grain of powder and that of the decreasing sphere are $\frac{4}{3}\ R^3$ and $\frac{4}{3}\ \pi R^3(1-\frac{t}{t'})^3$ respectively; and their difference π or the quantity of powder burned, will be equal to $\frac{4}{3}\ \pi R^3(1-\frac{t'}{t})^3$. The first factor of this expression represents the primitive volume of a grain of powder, and the other expresses the relation of the volume burned to the primitive volume. The same expression will answer for all of the grains of a charge of powder, if they are of the same size and composition; consequently, if we let A represent the volume or weight of the grains composing a charge of powder, the quantity remaining unburned after the time, t, will be represented by $A(1-\frac{t}{t'})^3$; and the quantity burned by $A1-(1-\frac{t}{t'})^3$. Although the grains of powder are not spherical, their sharp angles are partially worn away by rubbing against each other in glazing and in transportation; and the mode of fortification and inspection reduces the variation in size within narrow limits; therefore, if we examine the influence which the actual form and size of the grains exercise over the phenomenon of combustion of powder, we shall find that the effect varies but slightly from that due to the spherical form. If we consider the velocity of the projectile on leaving a gun and the time necessary to overcome its inertia in the first period of its movement, we shall see that a very large portion of each grain is burned up before the projectile leaves the gun. If the size of the grain be increased, the effect will be to diminish the amount of gas evolved in the first instant of time, and to diminish the pressure on the breech. This principle has been made use of to increase the endurance of large cannon.

COMBUSTION ENGINE. See INTERNAL COMBUSTION ENGINE.

COMEDIE FRANÇAISE, kō'mā-dē' frän'-sāz', the official name of the national theatre of France which is supported by public funds for the purpose of advancing dramatic art. It was long known popularly as "La Maison de Molière," or Molière's Theatre, even after it had become, by royal decree in 1680, a national institution; and the two great bodies of actors then in Paris, those acting at the Hotel de Bourgogne Theatre and those at the Généguad Theatre, had been united and fused into one body. The former, which was Molière's dramatic institution, had originally been an old theatre where miracle plays had been presented as early as 1543. Thus the Comédie Française may be said to have an unbroken tradition reaching back to the days of Molière, and to have had theatre connections for more than a century previous to the death of the great dramatist in 1673. Two years after the amalgamation of the dramatic companies they received a royal grant of 12,000 livres ($2,400) per year; and seven years later they took, for the first, their present designation of players of the "Comédie Française." From 1770 to 1782 the "Comédie" had quarters in the royal palace of the Tuileries. But the Revolution of 1789 divided the players of the "Comédie Française" into two strongly antagonistic political parties and disrupted the organization to such an extent that all public performances were suspended. Each party reorganized, some months later, as an independent theatrical organization, the Royalists taking the name "Théâtre de la Nation" and the Republicans that of "Théâtre de la République." In 1793 the former theatre closed its doors and its players were arrested by the Committee of Public Safety; but they were subsequently released and allowed to again open their theatre. Napoleon, in 1812, issued regulations for the government

of the national theatre, which are still, with some subsequent modifications, in force. The government appoints a general manager of the theatre, the members of the stock company of which divide the profits according to laws and regulations prescribed by the articles of incorporation of the organization. The «Comédie Française» receives from the French government an annual pension of 240,000 francs. Its membership is divided into «sociétaires» and «pensionnaires.» The former are regular members of the organization and as such receive a pension of 4,000 francs a year after 20 years of service, while the latter are paid actors who may, after a certain length of service, become «sociétaires.»

The building of the «Comédie Française» was so badly damaged by fire in 1900 that it had to be practically rebuilt. This resulted in making the edifice much more modern in every way. The names of nearly all the great actors and dramatists of France have, at some time in their career, been associated with that of the «Comédie.»

W., 'The French Stage in the Eighteenth Century' (London 1888); Joannides, 'La Comédie Française 1680 à 1900' (Paris 1901); Lucas, 'Histoire philosophique et littéraire du Théâtre Français' (Paris 1862); Pougin, A., 'Dictionnaire historique et pittoresque du théâtre' (Paris 1888); Rigal, Eugène, 'Les Théâtres de Paris 1548 à 1635' (Paris 1887); Soubies, A., 'Almanach des Spectacles' (1890); Weiss, 'Autour de la Comédie Française' (Paris 1892).

COMÉDIE HUMAINE, ü-mān, **La,** a series of novels by Balzac, so designated by their author, and intended to form a picture of the manners and morals of the period. The first volume of the 'Comédie Humaine' appeared in 1829; but it was not until 1842 that Balzac adopted the general title. The author intended to present a panorama of his time in France, and he wrote nearly 100 novels without completing the herculean task he had set himself.

COMEDIETTA, kō-mā-dĭ-ĕt'ṭa (It. diminutive of *commedia*), a dramatic composition of the comedy class, but not so much elaborated as a regular comedy, and generally consisting of one or at most two acts.

COMEDONES, kŏm'ę-dōnz, a name applied to the little cylinders of sebaceous and epithelial substances which are apt to accumulate in the follicles of the skin and to appear on the surface as small round black spots. When squeezed out they have the appearance of minute maggots or grubs with black heads, and thence have derived their name. They are generally associated with a weak state of the skin as well as of the individual. Generous diet and tonic treatment with soap-and-water cleansing and friction will be useful; as an astringent to invigorate a debilitated skin, a lotion of corrosive sublimate (two grains) in emulsion of bitter almonds (one ounce) and dilute alcohol will be effective. See Acne.

COMEDY, a dramatic representation of a light and amusing nature, in which are satirized pleasantly the weaknesses or manners of society and the ludicrous incidents of life. Comedy took its origin in the Dionysian festivals, with those who led the phallic songs of the band of revelers (Gr. *kōmos*) who, at the vintage festivals, gave expression to the exuberant joy and merriment by parading about, dressed up, and singing jovial songs in honor of Dionysus. These songs were frequently interspersed with extemporized jokes at the expense of the bystanders. Comedy first assumed a regular shape among the Dorians. The first attempts at it among the Athenians were made by Susarion, a native of Megara, about 578 B.C. Epicharmus first gave comedy a new form and introduced a regular plot. That branch of the Attic drama known as the Old Comedy begins properly with Cratinus. It lasted from 458 B.C. to 404 B.C. The later pieces of Aristophanes belong to the Middle Comedy. The chorus in a comedy consisted of 24. The Middle Comedy lasted from 404 B.C. to 340 B.C. and the New Comedy till 260 B.C. Middle Comedy found its materials in satirizing classes of people instead of individuals. New Comedy answers to the comedy of the present day. The most distinguished of Roman comic writers were Plautus and Terence, whose plots were mainly derived from the Greek. See Drama; Literary Forms.

COMEDY OF ERRORS, The. This, Shakespeare's shortest play, is certainly one of his earliest. Conservative modern critics are inclined to fix upon 1591 as the probable date of composition and to place it second only to 'Love's Labour's Lost' in the order of the poet's independent works. To the general reader the comedy is chiefly known as Shakespeare's solitary effort at direct imitation of a classic model; and the neglect it suffers may be due to the mistaken notion that it is no more than a free rendering of the 'Menæchmi' of Plautus. The idea of the indistinguishable Antipholus twins and the rough pattern of their adventures, to be sure, come from the 'Menæchmi,' and certain other points from a second Plautine play, the 'Amphitruo' — notably the situation in Act III, scene I, where the true master and his slave are shut out of their house while their doubles revel within. Both in plot, however, and in development the Shakespearean play invents more than it borrows, and it deserves respect as an instance of the same kind of treatment of sources which marks the poet's maturest work. Short as it is, 'The Comedy of Errors' is vastly richer and more varied than the 'Menæchmi.' The clever notion of duplicating the twin Antipholi by twin servants (the Dromios) trebles the opportunity for mirthful misunderstanding; while the creation of the pathetic figures of the old father and mother and the charming sister-in-law, Luciana, introduces a depth of human feeling and a romantic atmosphere entirely alien to Plautus. The reader of 'The Comedy of Errors' will find many suggestions of later plays. Compare the old father Ægeon with Egeus in 'A Midsummer Night's Dream'; the business of the chain with the trouble over the ring in 'The Merchant of Venice,' and note particularly the forecast of 'Twelfth Night' in the story of the escape of the shipwrecked twins, their subsequent confusion and the episode of the supposed madman bound and laid

in a dark room. An English translation of the 'Menæchmi' was printed in 1595 and may conceivably have been accessible to Shakespeare in manuscript at an earlier date. It seems more likely that he got his general knowledge of this play as well as of the untranslated 'Amphitruo' while at school, where Plautus was often a regular subject of study. For the influence of Plautus on English drama in the 16th century, consult the introduction to M. W. Wallace's edition of 'The Birth of Hercules' (Chicago 1903). The 1595 translation of the 'Menæchmi,' with parallel Latin text and introduction, has been edited by W. H. D. Rouse in the 'Shakespeare Classics Series' (New York 1912).

TUCKER BROOKE,
Professor of English, Yale University, New Haven, Conn.

COMENIUS, kō-mē'nĭ-ŭs, or **KOMENSKY, Johann Amos,** Moravian educational reformer: b. probably at Nivnitz, Moravia, 28 March 1592; d. Amsterdam, 15 Oct. 1671. His family belonged to the sect of Moravian brethren. He studied at Herborn in Nassau and at Heidelberg. He became rector of a school at Prerau and later, after taking orders in the Church of the sect of his parents, accepted the position of pastor and rector at Fulnek. The plunder of that town by the Spaniards after the battle of Prague in 1620 cost him all his possessions and writings. He fled to Poland, where in 1632 he was elected bishop of his communion at Lissa. Here in 1630 was published his 'Pansophiæ prodromus,' a work on education which attempted to organize all human knowledge within reach of the minds of everyone. In 1631 there appeared his 'Janua Linguarum reserata,' which outlined his method of teaching languages through the vernacular and by means of illustrations and object lessons. This work obtained widespread popularity and was translated into many European languages as well as into Persian, Arabian and Mongolian. His 'Orbis pictus' was an abridgment of the 'Janua' with many illustrated cuts for use by children, and was the first of its kind. In 1638 he went to Sweden to plan a system of education for that country. In 1641 he visited England on a similar mission which was unsuccessful because the political upheaval made the time unripe for reforms of that sort. He therefore returned to Sweden in 1642, and, with the assistance of Oxenstjerna, worked on plans for the curricula and management of the Swedish schools. At Elbing, in West Prussia, whither he went in the same year, he worked on further elaborations of his schemes; and then continued both this and his religious duties at Lissa (1654). In the war which followed, he again lost all his manuscripts, and was obliged to flee. He went to Amsterdam, where he remained for the rest of his life.

His educational theories were remarkably broad and inclusive. His system of schools has not yet been superseded in practice. His efforts were directed toward arousing the interest of the pupil. In his curricula, music, economy, politics, world history and science were included. Education was to him a means of interpreting and enlarging every-day experience by use of its own terms as well as by means of the classics, religion and ethics. His writings on education are numerous. 'Didactica Magna,' the most comprehensive of his publications, reveals his attempt to make a science of education by approaching it by the same method as that employed by the physical sciences. At the celebration of his tercentenary, a society was formed for the publication of his works. His place in the history of educational reform is well merited in spite of the weaknesses of his scientific bases.

As a theologian he was mystical, a believer in prophecies, dreams and revelations. Among his works in this field are 'Synopsis physicæ ad lumen divinum reformatæ'; and 'Lux in tenebris,' a prophetic work. Consult Laurie, 'John Amos Comenius' (1881); Keatinge, 'The Great Didactic of Comenius' (London 1896), and Monroe, 'Comenius and the Beginning of Educational Reform' (New York 1900).

COMET (Greek, Κομήτης, the hairy one; Latin *coma,* hair; in either case a celestial body with a tail, an appendage which accompanies all bright and many faint comets). Comets move more or less rapidly among the stars, being visible over periods varying from a few days to many months at a given apparition, and their paths across the sky may take any direction whatever. Actually, however, all comets move under the law of gravitation in orbits which, but for perturbations, would be perfect conic sections with the Sun at one of the foci. Therefore their apparent paths, which often seem so peculiar, are combinations of their own motions and that of the Earth from which we observe them. The typical comet consists of three parts: nucleus, coma, and tail. The first two are often lumped into the single designation «head.» Very faint comets may apparently lack both nucleus and tail, even when viewed with the most powerful telescopes. The presence of the coma is necessary, however, if the object is to be classed as a comet, no matter what other criteria we may apply.

Historically, comets were recorded certainly as far back as 4,000 years ago in China and not long after in Babylonia. Greek and Roman writers have numerous accounts of them, and most vivid and impossible descriptions of bright comets may be found in European writings as late as the 16th century. Naturally, only comets visible to the naked eye, and in general conspicuous, were recorded before 1608. Due to their unusual appearance and erratic movements in the sky, these bodies long ago acquired a terrible reputation for being the harbingers of war, famine, pestilence, and the death of kings. Indeed, a brilliant comet, with a tail stretching perhaps half across the heavens, would be a fearsome object to ignorant people. Today the advent of such a comet still would be viewed with superstitious terror by millions, even in the so-called enlightened countries. But unless the Earth collided with its nucleus, a comet could cause no possible harm to us. The chances are millions to one against a collision with a given comet.

Classification.—Comets are generally classed according to the type of orbit in which they move. Those whose periods can be calculated, evidently move in ellipses, which are closed curves. A very few, which have had their speed increased by their near approach to some large planet, move off in hyperbolic orbits, and hence leave our solar system forever. As

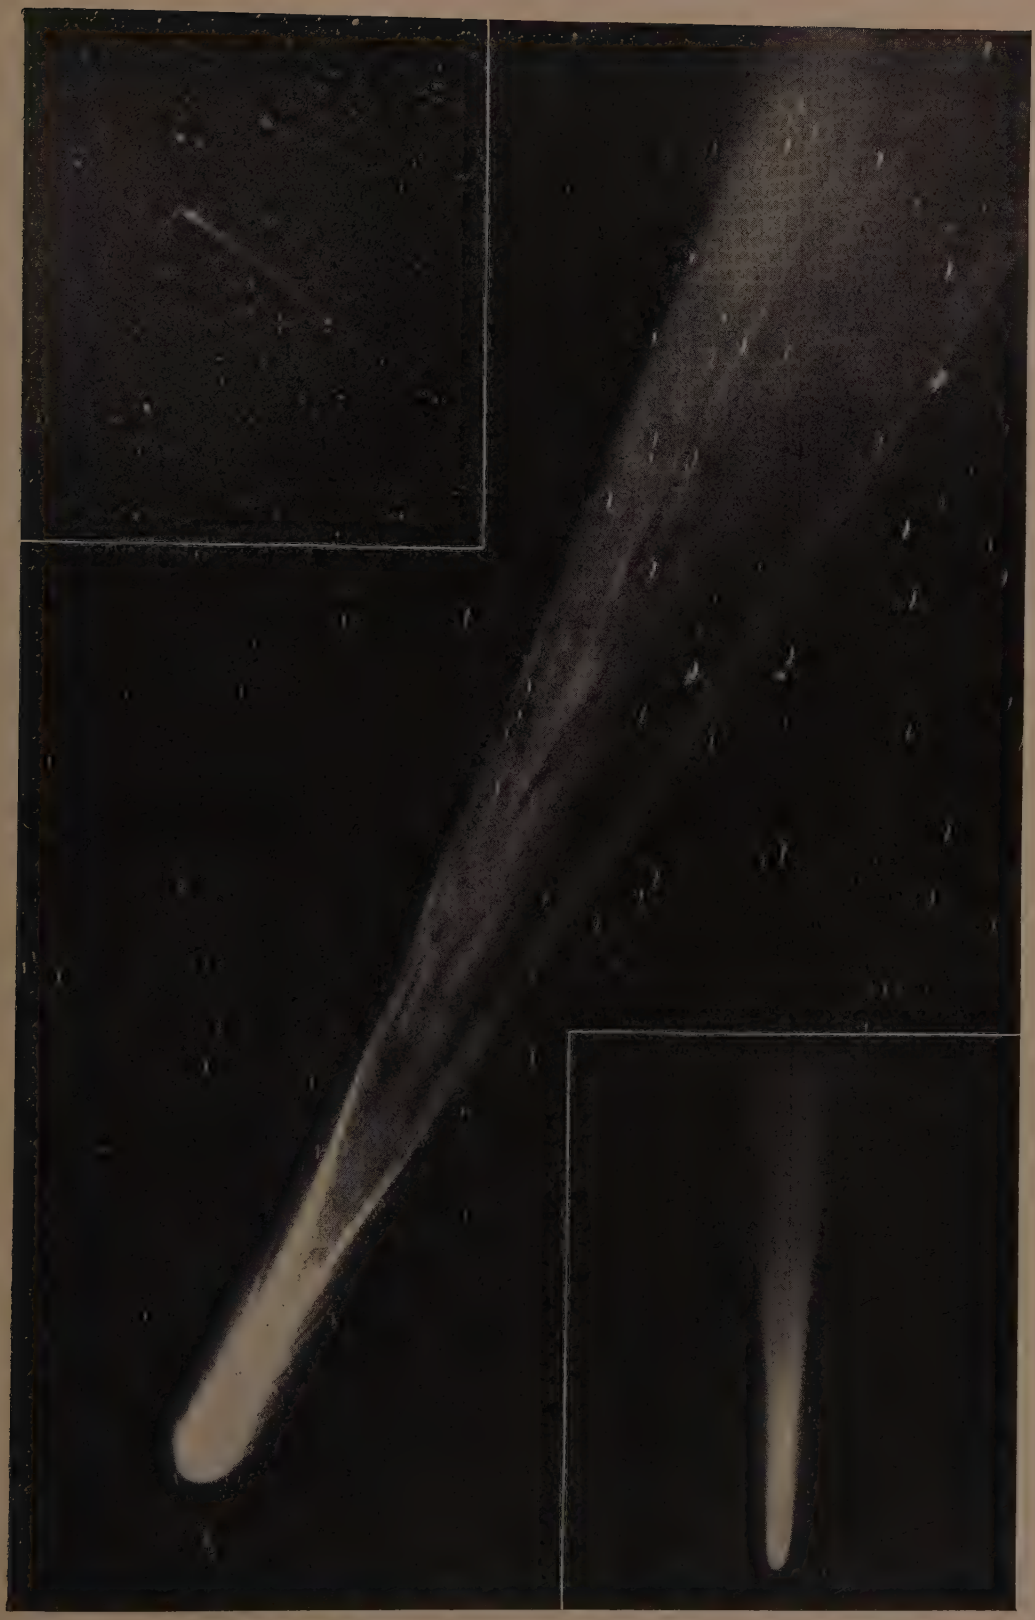
for the rest, which are the majority indeed, they are described as moving in parabolas. This curve is, strictly speaking, also an open one. However, the description of motion as being parabolic is only an approximation. We are now certain that all such comets move in very elongated ellipses, with periods extremely great. They are described as parabolic because that curve is far easier to compute than the ellipse, and this assumption fits the observations equally well. This is due to the fact that we only see the comet in that very short arc of its orbit when it is near the Sun, and observations on a hazy object cannot be made with great enough accuracy to differentiate between an ellipse with a period of 10,000 or 20,000 years and a parabola. In such a case, the parabolic orbit is taken as representing the data, which it does to all practical purposes. Even for those comets with definite elliptical orbits, if the periods turn out over 1,000 years, we do not have much faith in the exactness of the period computed. When a comet, either coming toward or going from the Sun, nears a large planet, according to their relative positions its speed may be either increased or lessened. In the first case, its period is made longer and in extreme cases it may then go off in a hyperbola. In the second, its period becomes less. Comets which now form Jupiter's family are presumed to have been «captured» by that planet in the way described. The criterion for belonging to Jupiter's family is that the aphelion points of the comets' orbits shall be somewhere near the planet's orbit to which the planes of their orbits are actually little inclined. Their periods will be less than 12 years and they move with direct motion as do the planets. About 41 comets are considered to belong to Jupiter's family, but certain of them have been lost to view, probably permanently, for causes to be discussed under another head. It is doubtful if the so-called families of the other planets are real.

Composition.—In describing the parts of a comet, it is now generally agreed that the nucleus is made up of a vast number of small, solid masses, separated from one another by spaces considerably larger than their dimensions, but which, in the aggregate and seen from a great distance, usually look like a single body. There are strong reasons for believing that these masses resemble, in size and composition, the meteorites which reach the Earth's surface. It is not possible to place exact limits on the dimensions of the separate masses, but they certainly are relatively small. Many comets never show a nucleus, even when observed with large telescopes. It seems, however, that one must be present to give enough gravitational attraction to hold the comet together. In such cases, the small pieces are presumably too scattered through the central part of the coma to show up as described above. Near the Sun, the nucleus of a large comet sometimes divides into two or more parts. The coma is a hazy mass of gas and the finest dust, the nucleus being about central therein. At a distance from the Sun, the coma is small and faint. As the Sun is approached, the coma greatly expands until a critical point is reached. Here, despite nearer approach with greater heating, the coma begins to contract again. Probably this critical point is where the formation of a tail begins. (See 'Comets' by C. P. Olivier, p.28, 1930, for a fuller explanation). The tail continues to expand in volume and length until the perihelion point, i.e., that nearest the Sun, is just passed. Shortly thereafter, the coma begins to expand again, which continues until another critical point is reached, about where the tail ceases to exist. Thereafter the coma contracts until the object disappears from increasing faintness. As said, the maximum development of the tail is just after perihelion passage. The tail, however, is acted on by repulsive forces from the Sun so that, as the comet approaches, the tail follows its parent body; but as the comet recedes from the Sun, the tail precedes the comet.

It is certain that, at a great distance from the Sun, the normal comet is a dark body shining by reflected light from that luminary. As it approaches, the expansion can be readily explained by increased heating. But also, at about the distance at which a tail begins to form, the comet begins to shine with additional light. This is evidently some form of excitation, set up within its own body and due to solar energy absorbed, which then sets this secondary mechanism into action. The comet's brightness thereafter increases very rapidly, as a rule, as perihelion is neared and the decrease, following the passing of that point, is also rapid, though not quite at the same rate since there is always a lag in any phenomena due to heating. The particles, both gas molecules and fine dust, which constitute the tail, must come from the head. In general, it is believed they are expelled from the solid masses in the nucleus as these become more heated on nearing the Sun and most actively on the sunlit side as is evidenced by the formation of envelopes, when present. It is now a well-known fact that radiation exerts pressure, which becomes more and more effective as the ratio of the surface to the mass of a particle increases. When a dust particle has a diameter of about one-third the wave length of the radiation falling on it, such a particle is repulsed most efficiently. Repulsion is probably even more effective on isolated gas molecules which are constantly absorbing energy from sunlight. This almost inconceivably fine dust, expelled from the nucleus, is then all pushed away from the head in a direction away from the Sun and goes into the formation of the tail. At times definite knots of such matter can be traced for several days, traveling farther and farther back from the head. Observation, as well as theory, shows that such condensations travel with hyperbolic velocities and hence leave the comet never to return. The magnitude of the repulsive force, in different cases, varies from just greater than gravitation to at least 40 times as great. The same repulsion acts upon all the single dust particles and molecules in the tail. Hence a comet's tail is a thing always wasting away, and constantly having to be renewed from the head. We know that on each circuit around the Sun every comet loses some of its material and goes away a little smaller than it came. Comets therefore are not permanent bodies like planets (q.v.).

Frequency.—Chambers calculated that up to 1900, 1,056 comets had been recorded. However, 335 of these were seen during the 19th cen-

COMET



Center, Brooks's Comet, photographed by E. E. Barnard, at Yerkes Observatory, 19 October 1911.

Lower right, the Halley Comet, photographed 7 May 1910, at Santiago de Chile, by Mills Observatory.

tury. Since 1900, the rate of discovery has been much higher, several being reported every year, the largest number being 11 in 1925. However, the 20th century so far has been singularly unproductive of very brilliant comets, as only a few have been moderately conspicuous; far the larger part could never be seen with the naked eye anywhere in their orbits. Comets are discovered either by being casually found on plates, which were being exposed to the sky for some other purpose, or by persons who make comet hunting a business. Such observers use telescopes of moderate size but large field of view. Pons is credited with finding 37 comets from 1801 to 1827; he still holds the record. He was the doorkeeper of the Marseilles Observatory. Comet seeking is very largely left to amateurs.

Variation in Size.—The actual size of a given comet varies tremendously according to how far it is from the Sun, and for other far more obscure causes, as yet wholly unknown. As typical of changes in volume, Encke's comet with a period of 3.3 years, the shortest known, in 1838, varied in diameter from 278,000 to 3,000 miles between 9 October and 7 December, thus dropping at perihelion to barely 1 per cent of what it was earlier. This comet is never a conspicuous object and only develops an insignificant tail. We may assume that most of the material proper for formation of such an appendage long since has been lost. Halley's comet in 1909–10, when discovered, was 13,000 miles in diameter, grew to 220,000 when the tail began to form, then dropped to 118,000 at perihelion. It later expanded to 315,000, and disappeared when still 30,000 in diameter, being too faint, not too small, to be longer seen. One of the most peculiar of all comets is Schwassmann-Wachmann I. Its orbit lies wholly outside that of Jupiter and within that of Saturn and therefore never closer than half a billion miles to the Sun. Its orbit has a small eccentricity also. This comet was noted on 30 April 1941, as being of 18th magnitude; on 29 August as of 13th magnitude; on 15 September as of 15th magnitude; on 18 September as of 11th magnitude. Yet in all this time, its distance from the Sun had varied little. It is to be remembered that a change from 18th magnitude to 13th magnitude means an increase of one hundred times in brightness. Also on 15 September it was a nebulous patch of light, on 18 September it was almost starlike. No one has ever given a reasonable explanation for such conduct, which cannot be predicted.

Several periodic comets, after one or more returns, have disappeared. In the case of the most famous, Biela's, the process of disintegration could be followed. First discovered in 1772, again in 1805 and later in 1826, the three returns were seen to be those of the same object, which turned out to be a member of Jupiter's family with a period of 6.6 years. An inconspicuous object, nothing happened worthy of note until the 1845–46 return, when, having shown only usual phenomena for 33 days after rediscovery, it was found to have divided into two comets. For the next three months various changes occurred and the companions varied in brightness. Also they separated further. Each had a short tail. In 1852, the twin comets returned, now 1,500,000 miles apart, but moving in parallel orbits. Never again was either seen, but on 27 Nov. 1872, when the Earth passed the nearest to the comet's orbit, which incidentally almost intersects ours, a gorgeous shower of meteors was encountered. Calculation showed that these meteors followed the same orbit as had the comet. The shower returned in 1885, 1892, and 1899, becoming less and less rich. Since then it has disappeared. We here have an example of what happens to a disintegrated comet: its debris forms a meteor stream. In several other cases the presence of a meteor stream following approximately the same orbit as a comet is definitely known, though in most of these the comet still exists The obvious explanation is that comet and meteor stream are both parts of the disintegration of some super-comet, the present comet being the larger fragment of the parent body. Tuttle's comet and the Perseid meteors of August, the latter the best and most reliable annual meteor shower, furnish an example. Halley's comet and the Eta Aquarid meteors furnish another. It is obvious that meteors, being themselves solid bodies, could come from the comet's nucleus only; the tail material is entirely too small to give off meteors and also particles in the tail do not move in the comet's orbit. It is not meant to infer that comets are the sole birthplace of meteors, but they are the one which so far is generally admitted by everyone.

Study of Spectra.—The study of the spectra of comets has shown that of the coma to be due to molecules of neutral carbon, the Swan spectrum, and of neutral cyanogen. We also find, when near the Sun, a continuous spectrum with many dark Fraunhofer lines. Sodium has several times been detected, and iron and nickel in at least one case. The typical cometary spectrum may be described as continuous with bright bands superimposed. The nucleus itself presents an emission spectrum, made up of a series of radiations, which are always the same but not yet identified. The tail is formed of molecules of ionized carbon monoxide and ionized nitrogen. Spectral analysis thus shows that the coma and tail of a comet are constituted of very rarefied gases emanating from the nucleus. Dust is also present. Under the Sun's influence, electronic and photonic bombardments, these gases become luminescent and emit principally band spectra due to molecules. Metallic lines only appear in the rare cases when the comet approaches very near the Sun and must be due to the heating of the solid particles in the nucleus itself, which doubtless sets up other reactions.

Estimated Weight.—The only way the mass of any body in space can be determined is by its attraction for some other body. So far, while comets have had their orbits completely changed by their near approach to planets, in no case has any change in the planet's period been observed, due to the reciprocal attraction of the comet. This simply means that the mass of the comet is too small to be thus detected, but not that the comet weighs practically nothing. For instance, the Earth weighs 6.59 sextillion tons. If a comet weighed only one millionth as much, it would still weigh 6.59 quadrillion tons. Yet such a small mass would only show up by perturbations under the most favorable circumstances. Calculations by Orloff

on Halley's comet gave that the minimum mass of the nucleus must be 30 million tons. Most smaller comets would, of course, weigh far less. Others calculated that the matter in the tail weighed only one over four sextillion times what a similar mass of air would weigh. The Earth, passing through such a tail for a whole day, would pick up only a few hundred tons of material, including both dust and molecules of gas. The mean density of a comet is extremely low. If a comet were 80,000 miles in diameter, quite a moderate estimate for the average, and had a mass of one millionth that of the Earth, its average density would be only one 230 thousandth that of air at sea level. This approximation to a vacuum can be attained only by excellent air pumps.

Orbits of Comets.—If a number of comets travel in almost the same orbit but with periods such that the objects in question cannot possibly be the same body, they are said to belong to a comet group. The most famous is that consisting of the great comets of 1668, 1843, 1880, 1882, and a lesser one in 1887. The most notable thing about all five is that, at perihelion, they passed within less than half a million miles of the Sun's surface; thus, for the few hours it took them to make the complete turn, they were exposed to a very high temperature. The 1843 comet passed only 78,000 miles from the Sun's surface, having at the time a tail estimated at over 150 million miles long, or long enough to reach to the orbit of Mars. Hence, had the tail been a solid appendage, the end of it would have had to move at a speed of 56,000 miles per second, or over a fourth the velocity of light. The obvious absurdity of this is one good reason for the conclusion that a comet's tail is not continuously made up of the same particles, the outer ones being lost, and others being constantly supplied from the head. The Great Comet of 1882 was perhaps the finest of the century. It was discovered in New Zealand on 3 September, as a naked eye object. It transited the Sun on 17 September, and, though followed right up to the Sun's limb by able astronomers, it there disappeared suddenly and completely. The nucleus had been five seconds of arc in diameter, an object which should have been easy to see on the solar disk had it been one mass. It was visible nine months altogether and had its orbit excellently determined. The nucleus, subjected as it was to a temperature of 3,000° C., broke up at perihelion into four parts, furnishing another example of how comets disintegrate. The period of the comet before this was of the order of 800 to 1,000 years; after it, the separate four parts went off from the Sun with slightly different speeds, indicating periods which should bring them back in 664, 769, 875, and 959 years, respectively. Thus one great comet will return as four smaller ones, though on the way out this time all the parts were still in the original head, and so the definite separation is a thing for the future. The comet of 1887 was strange in that it never had any condensations in the head, thus making accurate observations of its position most difficult. It would be a good guess that all these five comets themselves once formed parts of a super-comet, long since broken into many pieces by the same forces which disrupted that of 1882 at its last appearance.

Donati's comet of 1858 was discovered on 2 June when a faint nebulous object and 250 million miles from the Earth. By September it had become visible to the naked eye and had a short tail; by early in October its length had reached 36°; by 10 October, 60° and it was by then sensibly curved, the upper convex side being better defined than the lower side. In the telescope this was one of the most interesting and beautiful of all comets, particularly from the series of envelopes expelled from the nucleus. These were circular or parabolic, and concentric. At first three distinct ones were visible, the outer diffused, the second better defined and brighter, the third, separated distinctly from the second by a darker interval increased in brightness towards the nucleus. On the back or tail side, a large sector was missing from all the envelopes, this space behind the nucleus being very dark. Eventually, seven envelopes in all were expelled, the highest going out to 18,000 miles, the last to 6,000 miles. The nucleus showed the phenomenon of decreasing in both angular and linear size as perihelion was approached. This comet was visible to the eye 112 days, with the telescope 275 days, and the tail could be seen 177 days. It was a most magnificent object at its brightest. Its orbit is a long ellipse, the period being about 2,000 years. It is possible that a bright comet, mentioned by Seneca, that appeared in 146 B.C. was Donati's comet.

The Great Comet of 1861 was notable not only for its brightness and apparent size, but, in America at least, its appearance was considered prophetic by many. It, too, was discovered in the Southern Hemisphere, by an amateur, J. Tebbutt. It did not become visible to northern observers until 29 June. The next night it was described as having a head whose area equalled that of the full Moon, and its integrated light that of the planet Jupiter. The tail was 95° long, stretching more than half across the sky, being 3° wide in the brighter part. About 6 P.M. on 28 June, the comet's head was 13 million miles inside the Earth's orbit and exactly in its plane. Two nights later it is certain that the Earth passed directly through the tail, the only phenomena noted being a peculiar illumination or phosphorescence of the sky. The crossing had not been predicted, so only casual observers saw the results. The delay of two days, from 28 to 30 June, after the comet's head passed the plane of our orbit to our entrance into the tail, is fully explained by the curvature of the latter. Eleven envelopes were said to have been expelled from its head in the interval 2 to 19 July, a new one rising every second day.

Morehouse's comet of 1908 moved in a retrograde direction and in a path sensibly parabolic; and at perihelion it was only slightly inside our orbit. It barely became visible to the naked eye. But due to the remarkable and violent changes that took place in its tail, it turned out to be one of the most interesting comets on record, as photography could make an accurate and permanent record of these changes, a thing not possible 40 years before. One of the most remarkable occurred on 30 September, thus described by Barnard. On 29 September, already disturbed conditions were evident but on the next night the first plate showed a small head with a thick straggling

tail. On the next, the whole tail had moved out bodily and only a slender neck connected it to the head. The tail was wide and large, being curved and brighter on north side. Fluffy masses projected out. On third plate, the tail appeared cyclonic, and was about to totally separate from the head. On 1 October, the great mass of matter which had formed the tail the previous night was now 2° out and attached by a slender thread. On 2 October, the tail was a system of broad curving streamers. On 3 October, it consisted of a widely diverging skeleton framework. Equally strange changes occurred on 15 October.

Comet 1910a, as so many other bright ones, was discovered in the Southern Hemisphere, passing perihelion on 17 January. The next day, to northern observers, it was plainly visible in full daylight only 4° from the Sun and much brighter than Venus, then 30° distant. It had a short, bright, curved tail about 1° long. The nucleus was at first sharp and bright, later it became elongated, then again round by 28 January. The greatest length of tail was perhaps 30° and it became plainly forked. Its head was of about the first magnitude for a few days, but its light was only of the 8th magnitude by 12 March; 13th magnitude a month later, and it disappeared in June when of the 16th magnitude. For a day or two, this was probably the brightest comet seen since the 20th century began. At first, the computation of the orbit of this comet gave exceptional trouble, but eventually it was formed to move in the retrograde direction in an orbit so nearly parabolic that no period could be computed. It will hence not return for at least many thousands of years.

The most interesting of all comets from the historical standpoint is Halley's comet; also it is fairly typical in its behavior and serves as an excellent example of how these bodies may usually be expected to act. The comet moves in a retrograde direction in its orbit, i.e., with the hands of a watch as seen from the north. The inclination to the Earth's orbit is only 18°, and its period varies from 74 to 79 years at different returns. This variation is wholly due to the attraction of the planets. A bright comet seen in 467 B.C. may have been Halley's; it was certainly seen by the Chinese in 240 B.C. and every successive return, or 28 more, have all been identified. Hence our certain knowledge of this body goes back without a break for over 2,000 years. It is named after Sir Edmund Halley (q.v.) because he was the first man who brought forward proofs that the comets seen in 1531 and 1607 moved in practically the same orbit as that observed by him in 1682. As they were all bright objects, he had the sagacity to infer they were really different returns of the same comet and so predicted that the next would occur in 1758. Comets had not previously been considered members of the solar system and his prediction was discounted by many. As he died in 1742, he did not live to see the vindication of his work for the comet was rediscovered on Christmas night in 1758. This finally settled the fact that some comets at least, and inferentially all, moved around the Sun in ellipses like the planets, only having their orbits very much more elongated or, as astronomers would say, in orbits of greater eccentricity. In the 19th and early part of the present century, manuscripts from China, Japan, and Korea became available, and other older European ones were found. On the basis of these accounts, rough orbits, but accurate enough for identification, could be computed for all the returns mentioned. As it comes back four times every three centuries, naturally it has often appeared near some historical event of great importance and so was readily connected therewith by our superstitious ancestors. For instance, that in 66 A.D. presaged the destruction of Jerusalem five years later according to Josephus. That of 451 coincided with the Battle of Chalons when Attila, King of the Huns, was defeated; that of 1066 with the Norman Conquest of England and it is indeed pictured in the famous Bayeux Tapestry, still surviving; that of 1456 came three years after the conquest of Constantinople by the Turks when the European nations were in deadly peril of all falling under their rule. The comet was so feared that the Pope, Calixtus III, ordered special prayers to be offered for deliverance «from the devil, the Turk, and the comet.» At later returns, the more general spread of knowledge seems slowly to have robbed the comet of some of its terrors, and perhaps it is no longer quite so conspicuous as in ancient days. The returns of 1758 and 1835 were of no special inherent interest, but we shall more fully describe that of 1910, since the comet was then seen by millions who are still living. The task of computing exactly what orbit the comet had pursued during the 74 years when it was invisible, that is from 1835 to 1909, was a great one, as the perturbations of the planets had to be allowed for during all this interval. This colossal work was brought to a successful conclusion by two English astronomers, Cowell and A. C. D. Crommelin. The comet was discovered photographically on 11 Sept. 1909, at almost the exact point predicted and was followed in the same way until June 1911, when, beyond Jupiter's orbit, it simply became too faint any longer to impress its image on the plates.

During this interval of nearly two years, it was observed with telescopes of every kind and literally thousands of visual observations and photographs were made. The popular interest in this best-known of all comets was also immense. However, due to its relative position to Sun and Earth, the comet was a disappointing object until it passed perihelion on 19 April 1910, from which date for the next two months it was brilliant and interesting. It was seen in the morning sky until we passed actually through the edge of the tail on 19 May.

As the probable passage through the tail had been widely publicized, many people became uneasy over the prospect of the poisonous gases, known to be present in a comet's tail, contaminating our atmosphere with dire consequences to life. As was explained, the amount thus picked up was too small to be detected. Unfortunately, brilliant moonlight on the night of our passage through the tail wholly prevented the seeing of any faint illumination in the sky which might have come as a consequence. During this interval until 19 May the nucleus and coma both showed remarkable changes, and sometimes jets appeared. Often the head as well as ejected envelopes would

not be symmetrical in shape. Though the comet was meantime leaving the Sun, it was approaching the Earth, so while the actual length of the tail must have grown less, its apparent length grew greater. The writer, then at Lick Observatory, California, on 18 May was able to trace the tail over an arc of 140°, about three-fourths of the way across the heavens. Of course, the parts further from the head grew fainter and fainter, but that near the head was bright and most striking. The comet crossed the Sun's disk on 18 May, but it was during the night for Europe and America. At Hawaii, most careful visual and photographic observations utterly failed to show the nucleus projected on the Sun. This was a further proof that the nucleus is not one solid body, but made up of vast numbers of small ones. Such a mass would be invisible against the Sun's disk. The head of the comet, meantime, had never been very brilliant, probably only comparable to stars of the second magnitude; it was the long and beautiful tail which made the object conspicuous. By 21 May, the head and 20° of the tail were seen in the evening sky, the latter much foreshortened due to projection. A broken part of the tail could be traced on successive photographs, taken at intervals of many hours on 6 June, as it receded from the comet's head. The velocity of this recession finally reached 36 miles per second. By the end of June the comet ceased being a naked eye object. It was last photographed 11 months later, when of the 16th magnitude. It should next return about 1985. Incidentally, it is the only periodic comet, now known, which may be classed as a bright object and which will return during the rest of the century. Those of shorter period are, in general, faint and inconspicuous objects, only a few of them being dimly visible to the naked eye.

Two of these short period comets which have been observed at a number of returns are of special interest. The first, Giacobini-Zinner's, discovered in 1909, and having a period of 6.04 years and an orbital inclination of 31°, is known to have a dense meteor stream moving in its orbit. On 9 Oct. 1933, three months after the comet had passed perihelion, the finest meteor shower seen during the 20th century was observed from Europe. Calculations proved that the meteors followed the same orbit as the comet. The Earth missed the stream in 1939. The other comet, Pons-Winnecke's, was discovered in 1819. In 1933 its period was 6.16 years, inclination of orbit 20°, and perihelion distance 1.10 astronomical units, which shows that its orbit lies wholly outside that of the Earth. But the shape and size of this orbit have undergone continual changes from its discovery to the present, well illustrating the effects produced by planetary perturbations. In 1819, for instance, its period, inclination, and perihelion distance were respectively 5.62 years, 11°, and 0.77 astronomical units. This last was well inside our orbit, but between 1915 and 1921 the transition took place. The interesting result was that 28 June 1916, when the Earth passed the node of the comet's orbit, quite a good meteor shower appeared. Calculations proved that these meteors followed the comet. Unfortunately, as the orbit was shifted later wholly outside ours, we can no longer meet meteors moving therein. Of very recent comets, at least two became bright enough to attract considerable attention. Cunningham's, discovered late in 1940, was visible to the naked eye in December of that year and indeed became a bright object in January, as seen from the Southern Hemisphere. The presence of two molecules, namely nitrogen hydride and hydroxyl, previously unidentified in comets' spectra, were detected in Cunningham's comet. Paraskevopoulos discovered a bright comet 23 Jan. 1941. By February, it was well visible in North America. At brightest the head was of second magnitude and a tail several degrees long was easily visible. The periods of these two comets yet remain uncalculated and are presumably long.

As the distinction between the effects of a collision of the Earth with the nucleus of a comet or with a very large compact mass of meteoric bodies can scarcely be made, and as we know, the former exist and can only infer the possible existence of the latter, the writer believes that the larger so-called meteoric craters were really due to our meeting with the nuclei of comets. The largest crater, whose origin has been proved, is that in Arizona. The one instance of which we know something about the actual fall is that in Siberia on 30 June 1908. A study of these cases will prove that such a collision, while harmless to the Earth as a whole, were it to occur at a large city or in a densely populated area, could easily produce the death of millions and much devastation. It is not just the damage the masses would do as projectiles but the explosion produced on impact and the air waves set up which would do the great harm. As in all history we have no narrative, such occurrences are relatively rare.

When we come to theories of the origin of comets there is none generally accepted. The three types most discussed are: that comets originated in the Sun and were in some way expelled; that they were formed and still are being formed in a nebulous envelope surrounding the solar system and which, though at a distance far beyond the planets, accompanies it through space; that they are products of eruptions on the surfaces of the major planets. While it is easy to formulate ideas along any of these lines, so long as mere generalities are discussed, the moment these are confronted with known facts we find each and all inadequate. Even the behavior of single comets, well authenticated by excellent observations so that extensive data are at hand, cannot as yet be explained but partially or in isolated cases. In fact their changes are so remarkable that we even suspect forces may be at work, of a type as yet unknown to us. It is believed that the causes for the streaming of the tail away from the Sun are fairly clear; otherwise, theories are certainly inadequate as to what goes on in both nucleus and coma. The writer hazards the opinion that, when good and acceptable theories are available for all other types of celestial bodies, those dealing with the origins and behavior of comets will still be wanting, as it appears that they are by far the most mysterious of all the bodies in space.

Comets' (1937); Watson, Fletcher G., 'Between the Planets' (1941).

CHARLES P. OLIVER,
Director, Flower and Cook Astronomical Observatories, University of Pennsylvania.

COMET, in ornithology, one of a group of hummingbirds with long forked tails. One of the most imposing of all hummingbirds is the Sappho comet (*Cometes Sappho*), or bar-tailed hummingbird, native to Bolivia, but migratory, and in the winter generally visiting eastern Peru. Specimens are secured only with great difficulty, owing to the rapidity of the complex evolutions of the bird when on the wing. Mounted examples, gorgeous as they are, do not convey an adequate idea of the brilliancy of the plumage. The Phaon comet (*Cometes Phaon*) is equally magnificent, but larger. It also inhabits Peru and Bolivia. It is distinguished from the Sappho comet by the fact that the tail is wholly crimson red, while that of the Sappho comet is ruddy brown at the base and is tipped with a black band. See also HUMMING BIRDS.

COMFORT, George Fisk, American scholar and educator: b. Berkshire, Tompkins County, N.Y., Sept. 20, 1833; d. Syracuse, N.Y., 1910. Graduated from Wesleyan University in 1857, he studied archaeology and the history of the fine arts in Europe, in 1865–1868 was professor of modern languages and aesthetics in Allegheny College (Meadville, Pa.), and in 1868–1872 lecturer on Christian art and archaeology in the Drew Theological Seminary (Madison, N.J.). In 1872 he was appointed professor of modern languages and aesthetics in the newly established Syracuse University, where he organized the college of fine arts, of which he was dean from 1873 to 1893. In the latter year he became president of the Southern College of Fine Arts, at La Porte, Texas. He organized the Syracuse Museum of Fine Arts in 1896, and became its director. He was also one of the chief organizers of the American Philological Association, and from 1869 to 1874 its secretary. From 1872 to 1893 he was editor of the art department of the *Northern Christian Advocate.* He also contributed extensively to periodicals, and published *Art Museums in America* (1869); *Modern Languages in Education* (1886); *Woman's Education and Woman's Health* (1894); *The Land Troubles in Ireland* (1898); and a series of German textbooks.

COMFREY, kŭm'frĭ, the common name of the genus *Symphytum* of the natural order *Boraginaceae* or *Borage* family. There are about 20 species, all natives of the Old World, where many of them are used in household medicine or for forage plants. Attempts have been made to naturalize them in America for commercial purposes, but the experiments have not given much promise of success. There is but one known American species growing wild, *S. officinale,* naturalized from Europe or Asia. It is a coarse perennial weed, from two to three feet high, with flowers in long racemes. The roots are mucilaginous, and are supposed to have medicinal virtues as a cure for diarrhea. It is known also as a blackwort, bruisewort and boneset. In England the leaves, gathered while young, are sometimes used as a substitute for spinach, and some people of unrefined taste eat the young shoots after blanching them by forcing them to grow through heaps of earth. Comfrey stewed in sugar, with a small amount of paregoric added, makes a highly prized domestic remedy for coughs and bronchial irritations.

COMICS. As distinguished from the single cartoon, comics consist of a series of pictorial representations telling a story, developing a situation, or at least presenting the same character in varied circumstances. Comics may thus consist of single representations (as H. T. Webster's "The Timid Soul") appearing at regular or frequent intervals, or of a sequence of pictures appearing simultaneously as in the "comic strip" (for example "Blondie") or "comic book" (of which "Superman" is an illustration). The sequence of pictures is usually supplemented by "balloons" carrying dialogue, and frequently by captions which contribute to continuity. But it is of the essence of the comics (also known as narrative illustration, or the picture story) that the picture sequence should intelligibly tell the story in itself. Indeed, occasional strips (such as "Benny") have contained neither balloons nor captions. In the form of the picture sequence, comics have widened their appeal to such an extent that they have come to be a constituent feature of practically all newspapers, and their issue as magazines or books has become an appreciable part of the publishing business. In fact, comics have attained such extraordinary popularity as to have merited considerable study as a social phenomenon. The first comics were drawn largely around plots that exploited the humorous, the laughable and the ludicrous. Hence their name. Many contemporary comics follow this formula (as "Little Lulu" or "The Katzenjammer Kids"). The majority of comics today, however, are designed, not to excite mirth, but to tell a story of adventure (as "Terry and the Pirates" or "Captain Marvel"). They contain little that is "comic." Yet they are known, both to their public and their publishers as the comics, and seem likely to remain so.

Origin and Development.—Facts and figures on the growth of the comics were presented for the first time in an exhibition entitled the Comic Strip, its History and Significance, staged by the American Institute of Graphic Arts in 1942. The earliest sample of comic strip lineage in the exhibition was a drawing copied from a rock shelter in Cogul, Spain, depicting a buffalo hunt, a drawing thought to have survived from the Paleolithic period, which ended in western Europe about 2,500 B.C. While most of the narrative art of ancient civilizations picture the heroic or the sacred, in Egyptian tombs there are found records of more commonplace events and numerous scenes that are essentially "comic." Through the succeeding centuries, narrative art, with improved techniques and a broader range of communication, was used to record acts, thoughts, and feelings in terms ever reflecting contemporary human interest, whether in religious rituals, historical events, or sacred myths; and on occasion it proved a telling medium for propaganda. During the Middle Ages there appeared a group of artists who were able to convey an idea quickly and tell a story in line sketches. The great caricaturists of the 18th and 19th centuries, notably James Gillray (1757–1815), Thomas

Rowlandson (1756–1827), and George Cruikshank (1792–1878), were skilled in the use of sequence panels; Rowlandson even made use of balloons enclosing speech.

Comic Strip.—The basic features of the newspaper comic strip were so fully developed during the 19th century, in the comic sequences of European and American periodicals, that it was necessary only to adapt them to newspaper printing equipment and to discover the preferences of readers. Beginning in 1894, with a series drawn by R. F. Outcault (1863–1928) of the New York *World* depicting the antics of a clown and a dog at a picnic, newspaper comic strips grew in popularity and variety, enjoying a tremendous vogue between 1910 and 1930. Outcault later became celebrated for his "Yellow Kid" and "Buster Brown" comic strips. It is to be noted that these comics radically improved on primitive picture writing, by adding descriptive text, dialogue, and even reflection; moreover, in the early 1930's, a basic change in subject matter was evolved, in that the "funnies" were largely replaced by the adventure story, exemplified by "Little Orphan Annie," "Dick Tracy," and "Terry and the Pirates."

It has become a truism of the newspaper business that, next to front page news, the comics sell the paper. Continuous study of newspaper readership, conducted by the American Newspaper Publishers Association, has revealed that among newspaper readers, front page news is read by 98 per cent of men, 97 per cent of women; the comics by 83 per cent of men, 79 per cent of women; editorials by 43 per cent of men, 27 per cent of women; political columnists by 25 per cent of men, 16 per cent of women. Among sizeable papers, only the New York *Times* is without a comic page. Comic strips—daily and Sunday—are read by well over half the nation's adults. The daily strips are read by two thirds of all children over six. On Sunday mornings, 40,000,000 people pore over the colored comic supplements. The comic strips—daily and Sunday—have a public of 70,000,000.

Comic Strip in Contemporary Culture.—Heywood Broun (1888–1939) called comic strips the proletarian novels of America. But this is misleading. Comic strips are read by all strata of our society, from the illiterate to the intelligentsia. True, intellectuals have shown favoritism toward certain strips, such as "Krazy Kat" and "Barnaby." But many of them adhere to strips soundly in the tradition—John Steinbeck, American novelist, and Dr. Hu Shih, Chinese scholar, favoring "Terry and the Pirates"; the late Judge Albert H. Gary, "Spark plug"; Pablo Picasso, Spanish painter, the "Katzenjammer Kids"; and J. Edgar Hoover, "Dick Tracy."

The size and range of the comics' public is equalled only by the avidity and absorption with which that public follows the adventures and misadventures of its favorite characters. When Milton Caniff portrayed the death of Raven Sherman in "Terry and the Pirates," 1,400 letters of sympathy poured in, a number accompanied by floral offerings. A Pennsylvania paper, which did not subscribe to the strip, carried the story of Raven's death as a news item. Caniff was interviewed on the radio, so he could explain why Raven had to die. On the day Raven was buried in the hills north of Chungking, 450 students of Loyola University of Chicago paid tribute to her by gathering on their campus, facing east for a minute of silence. When Smiling Jack was lost in the Pacific, Pan American Airways was urged by agitated fans to send out a rescue plane. When little Annie Rooney was pictured without gifts at Christmas, the papers which carried the strip were deluged with toys. When Blondie was expecting Cookie, second child in the Bumpstead household, she asked for suggestions for a name and 400,000 letters poured in. When, several years ago, Little Orphan Annie's dog Sandy got lost, her creator Harold Gray received a telegram he at first thought was a hoax. It read: "Please do all you can to help 'Annie' find 'Sandy.' We are all interested. Henry Ford."

Comic strip characters have become widely known and influential personalities in their time. Dick Tracy, Orphan Annie, and Terry, for example, have achieved radio fame. Several, like Popeye, have become stars in motion pictures. Blondie is featured in a daily strip, a Sunday color feature, a comic book, on the radio (by two networks—American and Columbia), and in pictures. Numbers of radio and movie characters—the Lone Ranger, Red Ryder, Donald Duck, and Mickey Mouse among them—have sought and achieved fame in the comics.

The impact of comics on our culture is seen at every hand. Comics have influenced our diet and health habits. The citizens of Crystal City, Texas, in the heart of the spinach country, raised a monument to Popeye; mothers petitioned E. C. Segar, his creator, to stop Popeye's opening cans of spinach with his teeth. Buster Brown set a fashion in boys' clothes. Comic characters have taken part in our politics. Little Orphan Annie and Daddy Warbucks were among the most vocal critics of the New Deal. *The Daily Worker's* ideological moppet, Little Lefty, fought it out with Orphan Annie over the rights of labor. The comic strip has gone to work for the Political Action Committee.

The idiom of the comic strip has left its mark on our language—in "heebie-jeebies" and "time's a-wastin'" (Barney Google), "goon" and "jeep" (Popeye), "let George do it" (Jiggs), "foo," "twerp," "bodacious," "banana oil," and many other slang words or phrases. Comic strip characters and exploits have livened our speech with simile and metaphor—*Time* has characterized a cinema hero as "mowing down the enemy like 'Superman' at harvest home." They have enriched our song (*Barney Google with the Goo-Goo-Googly Eyes*), our drama (they fathered the "movie" cartoon); our dance (Krazy Kat inspired a ballet); our art (Milton Caniff's drawings for *Male Call* were exhibited in 1945 at the Berkshire Museum; his drawings for "Terry and the Pirates" have hung in the Metropolitan Museum of Art).

The comics have invaded campus and classroom. "Sadie Hawkins Day" is celebrated at 500 schools and colleges. In more than 2,500 classrooms children are learning to read from Superman workbooks. The comics are teaching French, Spanish, and the social studies. *Ivanhoe,* and other classics, over which school pupils pore late into the night, are now reduced to comic form. The Chicago Museum of Natural History's Joe the Elk teaches paleontology and anthropology. Private Pete and his colleagues played a major role in the educational program of the armed forces. Even the Sunday school

is not exempt. In some 2,000 Sunday schools children are studying *Picture Stories of the Bible.*

Comic Magazine—Along with newspaper comic strips, and related to them in their technique and objectives, were developing between 1911 and 1934 the progenitors of the contemporary comic magazine—the familiar 64-page, four-color picture story magazine, published monthly or quarterly, known to its readers as a "comic book." Among these may be mentioned the publication, in 1911, by the Chicago *American,* of a collection of Bud Fisher's "Mutt and Jeff" daily strips; the 13 issues of a newsstand edition called *The Funnies,* produced by the Dell Publishing Company of New York, a one-color publication about an original character named Detective Dan; and the *Skippy* comic book, said to be the first four-color comic magazine, the picture-stories of which dealt with the adventures of one character. The latter, distributed as an advertising premium in 1934, ran into 500,000 copies.

To be sure, the first comic book was published nearly a century earlier. The first comic book known to have been published in America, preserved in the collection of the American Antiquarian Society, "The Adventures of Obidiah," was published by Wilson and Company, which specialized in the popular paper-backed novels of the period, in 1843. It deals with the adventures of one, Obidiah Oldbuck, in his pursuit of a reigning belle of the period. In the words of its publisher, "Herein are set forth the crosses, chagrins, calamities, checks, chills, changes and circumgyrations by which Obidiah's courtship was attended." Less artful than the contemporary comic book, and lacking its familiar balloons, "The Adventures of Obidiah" was none the less a lineal forebear of Joe Palooka, Gasoline Gus, Dagwood, and Superman. However, in the historical record of America's popular literature, there is a complete hiatus between "The Adventures of Obidiah" and a few of its contemporaries such as "Ferdinand the Flipper," and the comic magazine of the early 1900's.

The monthly comic magazine was the outcome of an idea developed at Eastern Color Printing Company, New York, suggested by a small broadside, which the Philadelphia Ledger Syndicate had published in 1933, of their Sunday comics for promotion purposes, using plates 6 by 9 inches. This company, itself then engaged in the printing of colored Sunday comic sections, conceived that a page, 7 by 10 inches, could be produced economically on a four-color rotary newspaper press and made up in units of 16 to 96 pages or more. The outcome was that 10,000 copies of a book called *Funnies on Parade* were reprinted from Sunday supplement cartoons for use by a large national advertiser as a premium. The next step, proposed by M. C. Gaines, at that time one of the company's associates and a leading figure in the development and production of comic magazines, was the issue of 35,000 copies of a book, *Famous Funnies,* for sale at 10 cents in five-and-ten cent stores. This book proved so popular that the publishers continued its production as a regular monthly magazine.

Later Developments.—Early in 1935 Maj. Malcolm Wheeler-Nicholson conceived the idea of a monthly comic magazine in tabloid size, containing not reprint but original material; his productions were *Fun* and *New Comics.* In the following year many other publications entered the field, and the editions became standardized in the familiar 64-page format. *Detective Comics,* appearing in 1937, is said to have been the first comic publication of an original nature to have had a definite editorial policy. It soon became evident that comic books and magazines of this character would far outstrip those with only reprint material.

Comic Magazine Formula.—The comic book has followed the trend toward the adventure story already noted in the later development of the comic strip. It is typically designed to tell a story of fantastic adventure—a story of breathtaking expectancy and sustained suspense, in which impending danger is challenged and overcome by a magical hero with superhuman powers.

The most successful comic book characters—Superman, Batman, and Captain Marvel—all adhere closely to this formula. The bimonthly magazine bearing Superman's name had a circulation in 1945 of 1,500,000 per issue. As a comic strip hero, he appeared daily in newspapers with an audience of more than 25,000,000. As the hero of a radio serial, he was heard three to five times a week throughout the United States and Canada. *Time* rightly called Superman the number one juvenile vogue in the United States. Batman and Captain Marvel were not far behind Superman in popularity. Wonder Woman, the popular female counterpart of Superman, created by the psychologist, Dr. William Moulton Marston, as well as the animal heroes, who grew in popularity with younger children—Mickey Mouse and Bugs Bunny among them—also adhered closely to the comic book's typical formula of fantastic adventure.

Comic Magazines Reading Public.—The extent of the comic book's reading public is one of the amazing phenomena of our culture. A survey conducted by the Market Research Company of America (1944) on the reading of comic books throughout the country revealed that comic books had as large, if not a larger public, than had the comic pages of the newspapers. Of children 6 to 11, 95 per cent of boys and 91 per cent of girls read comic books regularly. Of adolescents 12 to 17, 87 per cent of boys and 81 per cent of girls were regular readers. Regular readers among adults numbered 41 per cent of men and 28 per cent of women between the ages of 18 and 30, 16 per cent of men and 12 per cent of women 31 and over (with another 13 per cent of men and 10 per cent of women occasional readers). Of men in training camps in the United States during World War II, 44 per cent read comic books regularly, another 13 per cent read them occasionally. At post exchanges comic books outsold *The Saturday Evening Post, Life,* and *The Reader's Digest* combined, by a ratio of 10 to 1.

True, education and economic and occupational status influence the reading of comic books. But their influence is less than one might suppose. Twenty-seven per cent of adults who are high school graduates, as against 25 per cent of those who attended only elementary school, regularly read comic books, though only 16 per cent of college graduates regularly include comic books in their literary diet. As many proprietors and managers (35 per cent) as unskilled laborers (38 per cent) are regular readers—although only 17 per cent of housewives, and but 12 per cent of school teachers are regular readers. Comic book readers, furthermore, like their comics in large doses.

To be a regular reader means among boys and girls that one should read an average of 12 to 13 comic books a month; among young men and young women 7 to 8 a month; among older adults, 6 a month.

Psychology of the Comic Magazine.—Psychologists and psychiatrists have speculated at length upon the reasons for the astonishing popularity of comic magazines. Dr. Lauretta Bender has pointed out that they deal with age-old themes familiar in the folklore, mythology, fairy tales, puppet shows, and even nursery rhymes of all peoples; that, like folklore, the comics are an outgrowth of the social unconscious in the psychoanalytical sense; that the problems of the relationship of the individual to the physical universe and his social world find expression through them; that, like folklore and fairy tale, they provide emotional release.

Certainly the reader is given the opportunity to identify himself with a hero who overcomes the physical forces and human aggressions which threaten us all. This identification is made the easier, in many comic books, by the device of the "changeling personality"—the crippled newsboy who, by saying the magical word "schazam" becomes the all-powerful Captain Marvel, or the typical American, Clark Kent, who becomes Superman. Certainly the hold of the comics on child and adult is deeply rooted in our emotional nature.

Other reasons for the popularity of the comics must not be ignored. Picture stories are universally intelligible (preschool children, illiterates, and those of foreign language background pore over them with the same absorption as those who can read their captions and balloons); their pictured action and primary colors are emotionally moving (particularly to those of less emotional maturity); and they are within the financial reach of all to buy. (In the case of many children the price of a comic book affords them the only opportunity to choose and purchase a book for themselves.)

Production.—In 1945 there were 150 comic magazines on sale in the United States, including approximately 40 monthlies, 30 bimonthlies, 35 quarterlies and many single release issues, with a total sale of about 35,000,000 copies per month. By that time, the industry had tripled the output of mill suppliers, and of half a dozen newsprint rotary color printing plants and binding establishments; eight engraving plants were making color plates for the comic books, four having been organized especially for this work. Over 500 script writers and artists were employed in special assignments or as staff members. The process of putting together a typical book is not a simple one. The story first is written in script form with instructions to the artist regarding illustration and lettering; from these the artist makes a layout and submits rough sketches to the editors for approval. The finished art work is done first in black and white, twice the size of the printed page, then photostated down to final size, hand colored and turned over to the engraver for the making of four-color plates. Physically, the comic magazine is totally different from any other type of periodical. The number of pages is fixed and does not fluctuate from issue to issue with the volume of advertising; and the content is stabilized, with adventures of the same characters portrayed in successive issues; that is, constantly new episodes are built around established personages. Each hero and heroine has definite traits, techniques, and reactions, and the integrity of their personalities must be strictly preserved. The development of successive stories is the result of many conferences between editors and their staffs. A thousand words is a low average for a single feature, and where the stories fringe on fact, accuracy is all-important. Art work involves a great deal of time and talent, for costumes and facial characteristics must be maintained; moreover, considerable research precedes the drawing of backgrounds, while the process of lettering in the balloons and other text, being substantially slower than setting type, requires more time.

The making of four color engravings also presents special problems. The color scheme artist, limited to approximately 15 color-values that will reproduce well from four solid, primary colors and screen combinations used, must consider the color-value for each panel as well as the composite effect of each complete page. Standard costumes worn by the heroes and heroines are inviolate as to color, even though buildings may turn out to be purple or beige as a result. The average press run is approximately 300,000; for the more popular comics it may be as high as 1,500,000 copies. Mechanical interruptions of any kind are extremely costly, as in many newsprint color plants, production schedules call for continuous press operation, 24 hours a day, 7 days a week. In the aggregate, behind each issue of a comic magazine lie more than a thousand hours of creative time and production skill; and it takes about 12 weeks from the writing of the script to the arrival of the book on the newsstand.

Some Early Objections.—In the effort to establish themselves as a new medium of expression, comic magazines were obliged to meet the criticism and opposition that every innovation arouses. They were indicted as "a poisonous mushroom growth" in the Chicago *Daily News* in 1940. Not understanding what was significant in this new medium of communication, critics pointed out that drawings and drama were crude; language, humor, and sentiment immature. The severest criticism focused on the fact that the most avid readers of the comics were children, whose ideologies are easily swayed. The National Congress of Parents and Teachers took up the crusade, and comic magazines were assailed as a "menace" to the thought patterns and reading habits of the younger generation. Opposition was particularly articulate when Old Testament stories began to appear in comic guise, shocked adults declaring them "sacrilegious." There was even a burning of comic books in one Midwestern community. But in the religious, as in the secular comics, the absorption and delight of children in the thrilling adventures of favorite heroes and heroines were too profound to be eradicated by the objections of parents, educators, or critics. The children themselves invalidated these objections simply by continuing to read the comics. Children approach comic magazines without prejudice. The childlike quality of many of the characters, which do the things the children would like to do, appeals to youthful imagination. It has been pointed out by psychiatrists that life is seldom as active or meaningful as children would like it to be; thus their need for real living and doing finds vicarious satisfaction in the exciting adventures of the comic per-

sonalities. Children also readily identify themselves with animals; they do not find it incredible that cats and dogs or ducks and mice behave and speak as men. Especially for the very young child, animal cartoons have irresistible fascination; Walt Disney's Mickey Mouse and Donald Duck unquestionably have played an important role in shaping the minds of youth. An older generation, nurtured on fairy tales and classical mythology, found it difficult to make the transition to comic magazines, but for modern children the comics are more understandable than are the *Arabian Nights*.

Other Opinions.—The comics, however, have not been wanting in defenders among persons qualified to judge of their influence upon, and educational value for, child readers. In an article written for the *American Journal of Orthopsychiatry,* Dr. Lauretta Bender states that the comics serve to help children solve the individual and sociological problems appropriate to their own lives. "Subject matter in the comics," writes Dr. Bender, "deals with fundamental problems presented in caricature form. Aggression is dealt with in most of the stories, but its purpose as carried out by the hero is to prevent hostile aggression by others. Punishment is a constant factor, but it is justified punishment. Social insecurity appears again and again as the plots unfold, and its usual solution is portrayed as being found in group loyalties . . . sexual problems concern the comic book writers very little at the present time . . . the nuclear problems which concern them are group aggression and group loyalties, the scientific problems of overcoming them, space and gravity, and threats of social and economic insecurity."

Dr. W. W. D. Sones, director of curriculum studies of the School of Education of the University of Pittsburgh, on the basis of a study of the comics' meaning for and effects upon children, comments:

"If comic books are ignored, ridiculed or forbidden, we encourage rebelliousness, the forbidden fruit is made more attractive and an opportunity lost to share an interest with the child. On the other hand, both in school and at home, this interest may be capitalized to promote growth and development. Analysis showed that a child in reading a comic book is practicing the same activities that are used in good reading instruction. He learns new word symbols through pictures of things or action, or in the context of the story. Interest in the story arouses need for identifying new words in order to carry the thread. He gets practice in recognizing new words through their appearance in many different settings. Allusion to history, science, geography and current events may be expanded into real enlightenment through discussion. Even scientific absurdities can be turned inside out to reveal actual scientific phenomena. . ." With this point of view Dr. Robert L. Thorndike concurs. He states that "comic books are making a real contribution toward the hundreds of thousands of words of reading experience which the child should have every year during the upper elementary and following years." Gweneria Williams, children's librarian of the Schenectady Public Library, and Jane Wilson, librarian of the Junior High School of Scotia, New York, on concluding a study of children's reading interests, pointed out that "children respond more swiftly to the bright, concise gaudiness of the comic magazines, which very quickly gets down to the brass tacks of story telling, than to the finely styled but slow moving juvenile story written for tender minds."

Effects of Criticism.—A number of publishers of comic magazines, aware of the power and potentialities of their medium, and of the criticisms leveled against it, soon enlisted the advisory services of educators and psychologists in evolving a purposeful editorial policy. It was the function of the latter to examine the comic magazines from educational, sociological, psychological, moral, religious, and cultural points of view. This approach resulted in better and more careful editing to obviate errors in taste, judgment, and fact. Vocabulary was raised to higher levels, wholesome values stressed, and definite patterns formulated. Publishers anticipated increased appeal to adults and, in their own interests, were desirous of improving editorial content, art work, reproduction, and format. While this trend was characteristic of but a minority of publishers, included among them were the largest and best established publishers of comic books, whose policies were expected to influence the field.

Comics as a Medium of Communication.—*The Journal of Educational Sociology,* in an issue devoted to "The Comics as an Educational Medium," terms the comics "A great new medium of communication," and comments: ". . . the comics have emerged as a major institution of our American culture. They are here to stay. We are but beginning to feel their impact. Their potentialities as a social force are tremendous. As with radio, it behooves us to understand the comics, evaluate them, learn to live with them, use them as a medium of communication."

Advertising.—The potentialities of the comics as a medium of communication were first recognized by advertising agencies. A number of agencies soon specialized in comics advertising, as others did in radio advertising, and many added specialists in comics production to their staffs. Because of its popularity, the newspaper comic page and the comic book afforded valuable advertising space. Rates reflected this fact, *Puck,* the Hearst Sunday comic supplement (Audit Bureau of Circulation—A.B.C.—net paid circulation 6,659,101 as of March 31, 1944), asking $9,500 for one third of a page; the monthly unit of the National Comics Group (A.B.C. net paid circulation 6,000,000 as of 1944) asking $2,800 for a page. Advertisements in comic pages and in comic books vary from standard copy, through copy illustrated by a comic artist to make it conform more closely to the spirit of the comic page or book (such as General Electric's copy illustrated by William Steig), and strips telling the story of the product (such as Kleenex Corporation's Little Lulu), to straight adventure stories (such as Pepsi Cola's Pepsi—the Pepsi Cola Cop, or Tootsie V M's Captain Tootsie) reserving the last panel for a commercial. A survey (1944) by Stewart, Brown and Associates of comic magazine advertising and product consumption, showed as might be expected, that the closer the advertisement conformed to the formula of the comics themselves, the greater its interest and appeal.

Propaganda.—The possibilities of the comics as a medium of adult education (or propaganda, depending on one's personal viewpoint) were soon increasingly exploited. The characters of both comic strips and books played an active role in World War II. Under the auspices of

the United States Army and Navy, the Office of War Information, the Treasury Department, the Red Cross, the Children's Bureau, and the Office of Education, they sold bonds, promoted salvage drives, organized victory garden clubs, kept citizens alert to sabotage, combated intolerance and absenteeism, solicited blood donors, recruited men and women for industry and the armed forces, and warned against overoptimism. *Master Comics,* at the behest of the War Writers Board, created Radar, the International Policeman, to mobilize opinion for an international police force for the postwar world.

In the 1945 mayoralty campaign in New York City, two of the three candidates for mayor took their platform to the electorate through comic pamphlets. The Treasury Department used millions of comic leaflets to promote the Victory Loan. The Public Affairs Pamphlets' *The Races of Mankind,* translated into comics, was distributed by the National Conference of Christians and Jews. Other Public Affairs Pamphlets were soon in process of translation into comics. The East-West Association, in the interest of mutual understanding between Orient and Occident, created a character, Johnny Everyman, whose adventures appeared in the quarterly unit of the National Comics Group. *All Star Comics,* with editorial advice from a national organization for the handicapped, devoted an issue to promoting better understanding of the problems of the physically handicapped. The Educational Department of the CIO undertook a series of strips, and issued its first comic leaflet, *With Victory.* It co-operated in the distribution of the comic *Scape-Goats of History,* a plea for understanding and tolerance among peoples, observing, "We find that information presented in this form makes a more popular appeal than the same facts presented in pamphlet form, as is evidenced by the 1,000,000 distribution of a comic strip, as compared to the 125,000 distribution of our most popular pamphlet."

Education.—Educators took an increasing interest in the possibilities of the comics as a medium of instruction. In 1941, The Parents Institute, publisher of *Parents' Magazine,* undertook to meet the criticisms being leveled at the fantastic adventure story, while exploiting the potentialities of the comics as a means of communication, by the publication of *True Comics.* As the name implied, *True Comics* made a feature of factual material in contrast to fiction and fantasy. While featuring adventure stories from the lives of heroes past and present, *True Comics* also published many factual stories. *They Got the Blame* (the story of scapegoats throughout history) and *There Are No Master Races* (written from the Public Affairs Pamphlets' *The Races of Mankind*) first appeared in *True Comics.* Among stories it featured were *The Story of America* (the script written by the historian, David S. Muzzey), *The Story of South America,* and *The Cavalcade of England.* Other stories dealt with current events, science, the social studies. While *True Comics* had but a moderate success in terms of paid circulation (the Market Research Company survey showing it to have half the circulation among children of "Superman," "Batman" and "Captain Marvel"), it has demonstrated conclusively a wide interest among children in factual stories presented in comic form.

Comics proved to have value in motivating learning as well as in presenting factual material. Harold Downes, of the Lynn Massachusetts Industrial High School, observing that many children who were slow in the development of reading skills, none the less pored over the comics, approached Superman D.C. Publications on the possibility of producing a *Superman Work Book* to teach reading. The work book was produced with the assistance of Dr. Robert Thorndike, educational psychologist. It proved so successful in motivating interest in acquiring reading skills that it was soon used in 2,500 classrooms. In *Junior Scholastic,* a current events magazine for use in the schools, comic strip presentation of history, geography, and science soon became a regular feature.

M. C. Gaines (originator of the comic magazine in its present format, and discoverer of Superman and Wonder Woman, two of the comic magazines' most successful characters), having watched the sales of his *Picture Stories of the Bible* mount to 3,000,000, and having witnessed its adoption as instructional material by more than 2,000 Sunday schools, became convinced of the value of the comics as an educational medium. He accordingly established, in 1945, the publishing firm of Educational Comics, Inc. Educational Comics, with the editorial assistance of a group of well-known educators, began producing frankly educational materials in comic book form, including *Picture Stories of American History, Picture Stories from Science, Picture Stories from Natural History, Picture Stories from Mythology, Picture Stories from Shakespeare,* and others. These educational comic books skillfully interwove the motivation of the adventure story (with which history, science, and literature are replete) with more formal and traditional maps of exploration, tables of dates, diagrams and charts, explanatory text, and teaching manuals. They were widely used in schools as supplementary instructional materials. Educational Comics, Inc., also published comics intended as a medium of adult education, among them *Out of the Past—A Clue to the Future,* for Public Affairs Pamphlets; *The Life of Carl Akeley,* and *Desert Dawn* for the American Museum of Natural History; and *The Bible and the Workingman,* for the CIO.

Evaluation of Comics as a Medium of Communication.—The variety and extent of usage of the comics (or picture continuity as the medium is designated by educators) in school instruction and adult education suggest the need of a technical analysis of this medium in relation to instruction and learning. Dr. W. W. D. Sones has taken the first step toward such an analysis. He finds that, when taken apart, the picture continuity has the following features: the narrative is presented in a sequence of pictures or cartoons; the focus of the narrative is always on people and rarely departs from the central character; animation is effected in the succession of pictures; sensory appeal usually is heightened by the use of colors; attention is held by brevity; finally, the theme and story are humanized to deal with popular feelings, thoughts, and actions. Each of these structural elements caters to the popular inclination, in reading activity, for vividness, action, brevity, and personalization. Perhaps the latter, the personal and human element, explains the moving influence of the medium.

Picture and text are not only complementary,

but frequently parallel. In relation to language structure, the typical comic magazine contains about 10,000 running words of reading matter with 92 per cent of the wordage among the most common 1,000 in the Thorndike Word List, a fraction less than 6 per cent distributed throughout the remainder of the list, and a fraction more than 1 per cent not included. The level of difficulty of the reading matter is at the fifth to sixth school grade. The vocabulary of comic strips is somewhat less difficult than that of comic magazines. The amount of wordage and the character of the vocabulary give the juvenile reader valuable practice in the reading art. The number of "word distortions" is not sufficient to influence language habits undesirably.

From the standpoint of structure and content, it appears the newspaper comic and the comic magazines can be appropriated for several different kinds of instructional activities. These usages may range from "horrible examples" serving as starting points to lead to the discovery of finer literary, language, or art forms, to their use as vehicles to realize the purposes of the school in the improvement of reading, language development, or acquisition of information. However, conceding such possible uses, what, if any, would be the gains over instructional instruments that are now employed?

Thus far there exists but a small amount of experimentally derived evidence concerning the effectiveness of the picture continuity in instruction. Dr. W. W. D. Sones carried on an exploratory study to determine the relative effectiveness of the pictorial continuity in relation to printed text in learning factual information for immediate recall. The life and work of Clara Barton was presented in picture continuity in the comic magazine *Wonder Woman* which, in reprint form, was made available for experimentation by the publishers. The story in textual form was copied from the pictured form. About 400 children in sixth and ninth grades were divided into 16 matched groups by grade and by three intelligence levels—lower, middle, and upper. The dividing lines for the latter were I.Q. 91 and 111. In each pair one group was presented with the picture continuity form and the other with the printed text form of the narrative. The reading was followed immediately by an objective test on the content. One week later the procedure was reversed and the groups retested by the same test. A strong trend in favor of the picture continuity was indicated by the two sets of results. In the first testing, for all but one of the picture groups the mean score was from 10 to 30 per cent higher than the paired printed text group. In the second testing, all of the eight groups who first read the printed text made significantly higher improvement in scores than did the paired groups who first read the picture continuity. Mean scores of the experimental and control groups on the second test were parallel. In other words, the picture groups seemed to have learned almost as much as they were capable of learning from their first reading, while the groups reading the printed text first had not reached the saturation point, but did so by a second reading in the picture form. Furthermore, while the brighter children learned, for immediate recall, practically the same amount from either picture continuity or printed text, the results favored the picture continuity for the low and middle intelligence levels.

Much more extensive study of the use of the comics in teaching is necessary before it will be possible accurately to evaluate them as a medium of instruction. This study must extend beyond the learning of the child in the classroom to adult education. As the armed forces make available the results of their evaluation of their educational program—in which the comics were widely, and seemingly successfully, used—much light should be thrown upon the usefulness of the comics as an instrument of adult education. Further, there is need to evaluate the usefulness of the comics as an instrument for influencing and imparting attitudes as distinct from factual knowledge. The East-West Association, in cooperation with the New York City Board of Education, has undertaken such an evaluation, using its "Johnny Everyman," who strives to promote interracial understanding and tolerance, as the vehicle for the study.

HARVEY ZORBAUGH,
Chairman, Department of Sociology, School of Education, New York University.

COMINES, kō-mēn, **COMMINES,** or **COMYNES, Philippe de,** French statesman and historian: b. Comines near Lille 1445; d. Argenton, Oct. 18, 1509. He stood high in the favor of Charles of Burgundy, afterward Charles the Bold, and on occasion of Louis XI's imprisonment by Charles at Péronne, succeeded in bringing about a treaty of peace between them. In 1472 he forsook the cause of the duke of Burgundy and became councillor and chamberlain of Louis XI, who compensated him so amply for the loss of his property, which had been confiscated by Charles, that he soon became one of the most wealthy and influential noblemen in France. The death of Louis, however, proved fatal to his fortunes. He was no favorite with Anne de Beaujeu, the regent, and was imprisoned on a charge of conspiracy against her. On the accession of Charles VIII, however, he was again employed in the public service, but went into retirement after the advent of Louis XII, who seemed reluctant to favor him, although he left him in possession of a pension. The fame of Comines rests not only upon his astuteness as a statesman, but still more upon his *Mémoires,* which give a complete view of the political affairs of his time, and present a vivid picture of the character of Louis XI. They have been frequently printed. Lenglet-Dufresnoy's edition (London 1747) is still sought for, especially on account of its annotations; but the best are those published by Mlle. Dupont (Paris 1840–1847); and Chantelauze (1881). Comines figures in Sir Walter Scott's romance of *Quentin Durward.*

COMING RACE, The, a story by Edward Bulwer-Lytton, published in 1871, concerning the Vrilya, or Ana, a race of imaginery creatures inhabiting a fantastic realm underneath the earth. A native of New York discovers them and, in the course of his visit, attempts to present an encomium on American democracy, only to be told that such a form of government is termed, in the Vrilya language, *Koom-Bosh* (government of the ignorant). The Vrilya have reached a scientific development many hundreds of years in advance of the modern world. The necessity for a laboring class has been obviated by the perfecting of all mechanical processes. Social equality is absolute. Belief in God and immortality is universal. In philosophy also, there is entire accord, and all the evils of life have been obliterated. Intended as a kind of travesty on some assumptions of science, the book attained great popularity, due to its clever and brilliant treatment and the speculations it aroused regarding human destiny.

COMITAT, kŏm'ĭ-tạt (L. *comitatus*), that which went with or accompanied the name given to administrative districts of some size into which Hungary and Transylvania are divided. In old English law comitatus, of which comitat is a contraction, was a county or shire. The comitatus were the personal followers of the king or earl, and the county or shire was the land of the comitatus or comitat. Hence the present use of the term in various European countries in the sense of a division of land.

COMITIA, kō-mĭsh'ĭ-a (Lat. "assemblies"), with the Romans, the assemblies of the people in which the public business was transacted, and measures taken in conformity with the will of the majority. They existed even under the kings. In the time of the republic they were convoked by the consuls; in their absence often by the dictator, the tribunes, and in extraordinary cases even by the pontifex maximus. There were three comitia among the Romans, which were called *comitia curiata, comitia centuriata* and *comitia tributa.* (1) The oldest of these was the comitia curiata, so called because in it the people voted by *curiae,* or wards. It consisted exclusively of the patricians, the original ruling class at Rome, and the class to which the name of populus was at first restricted. They were divided into three tribes, the Luceres, Ramnes and Tities, each of which was divided into 10 curiae, so that there were 30 *curiae* who voted in the comitia curiata. (2) The comitia centuriata was a mixed assembly of the patricians and plebeians, in which the people voted by centuries, as these had been formed by Servius Tullius. On the institution of this comitia the principal privileges of the comitia curiata were transferred to it, and in course of time the functions of the latter became a mere formality, so that even before the time of Cicero these were not performed by the *curiae* themselves, but by 30 lictors representing them. The rights of the comitia centuriata were thus very important, comprising the right of electing the higher magistrates, the right of passing or rejecting laws proposed to them, the right of deciding upon war on the ground of a *senatus consultum,* or decree of the Senate, and the highest judicial power. This comitia could be held only on certain days, and it must be summoned 17 days before the day of meeting. On the day of the comitia itself the presiding magistrate, with an augur, went into a tent before the city in order to observe the auspices. If the augur declared them unexceptionable, the comitia was held; if not, it was postponed to another day. Before sunrise and after sunset no business was transacted in the comitia. The presiding magistrate, on his curule chair, opened the assembly by a prayer, which he repeated after the words of the augur. In earlier times, first the equites, then the centuries of the first class, etc., were called upon to vote. In later times lots were cast for the order of voting. The opinion of the century which first voted was usually followed by all the rest. In the earliest times every century voted verbally; in later times by ballot. What was concluded in each century by the majority was proclaimed by the herald as the vote of this century. The comitia was interrupted if any one in the assembly was attacked by a fit of epilepsy (which was called for this reason *morbus comitalis*), or if a tribune of the people pronounced his veto, and under some other circumstances. (3) The other comitia, the comitia tributa, which was also an institution of Servius Tullius, was essentially plebeian in its nature, for if the patricians were not, as some think, entirely excluded from it, they were in so small a minority that their influence was scarcely felt. It was based upon the division which Servius Tullius made of the whole Roman territory into 30 local tribes, which were afterward increased to 35. Its power was at first very limited, being merely local, but it gradually increased, so that it in the end came to possess the right of exercis-

ing electoral, legislative and judicial functions, though not so extensive as those of the comitia centuriata. It had the right of electing only the inferior magistrates; legislatively, it was merely entitled to pass resolutions proposed by the tribunes, which before becoming law had to be sanctioned by the Senate; judicially, it had the right of trying only those who had committed offenses against the majesty of the people, and the only punishment it could inflict was a fine. It might assemble either within or without the walls of the city, but not at a greater distance than 1,000 paces, which was the limit of the power of the tribunes. The comitia centuriata, on the other hand, always met in the Campus Martius. Sometimes the comitia centuriata was mixed with the comitia tributa, but in what manner it is not known. The emperors retained these assemblies for the sake of appearance, but used them only as instruments for the accomplishment of their purposes. Consult Greenidge, 'Roman Public Life' (London 1901); Botsford, 'The Roman Assemblies' (New York 1909); Mommsen, 'Römische Forschungen' (Berlin 1879).

COMITIUM (Lat. "place of assembly"), a square in the ancient city of Rome between the Curia and the Forum, where the comitia curiata (q.v.) met. It contained the original rostrum or speakers' platform.

COMITLÁN, kō-mēt-län', or **COMITAN**, kō-mē-tän', Mexico, town in the state of Chiapas, on the Grijalva River, 35 miles southeast of San Cristóbal. It has a magnificent church and is a place of considerable trade. The town is largely engaged in agriculture and cattle raising, but has manufactures of cotton and woolen goods, liquors, etc. It is supported chiefly by contraband trade with Guatemala and British Honduras, as the duties on foreign goods are excessive. Comitlán suffered considerably from the raids of Juan Ortega in 1855–64. Pop. 10,196.

COMITY OF NATIONS (very frequently mentioned by its Latin equivalent, *comitas gentium*), the international courtesy by which effect is given to the laws of one state within the territory and against the citizens of another state. "In the silence of any positive rule," says Story, "affirming, or denying, or restraining the operation of foreign laws, courts of justice presume the tacit adoption of them by their own government, unless they are repugnant to its policy or prejudicial to its interests." The comity of nations rests upon common consent of the nations themselves and not upon positive law. In the United States the provisions of the constitution cover explicitly the question of comity between the States of the Union, in Art. IV, Sec. 1, which reads as follows: "Full faith and credit shall be given in each State to the public acts, records and judicial proceedings of every other State." This, however, only applies where a State has a right to act or render judgment for the federation. Consult Story, 'Conflict of Laws.'

COMLY, Samuel Pancoast, American naval officer: b. Woodbury, N. J., 13 July 1849; d. 10 April 1918; graduated United States Naval Academy in 1869. He was promoted through the various grades, became captain in 1905 and rear-admiral in 1909. He was on the *Juniata* in the Polaris search expedition of 1874. During the Spanish-American War he was in action at San Juan, P. R., and at the destruction of Cervera's fleet, 3 July 1898 In 1905–07 he commanded the *Alabama* and in 1910 commanded a division of the Atlantic fleet. In 1910–11 he was on court-martial duty and was retired in the latter year.

COMMA, the stroke or mark used in writing and printing to separate from each other phrases and clauses in a sentence. The word is of Greek origin and is the noun of the verb *kopto,* to cut; hence literally comma is section, and in grammatical works written in Greek and Latin *comma* or its diminutive *kommation* means a clause in a period as well as the punctuation mark, and in prosody the cæsura. In German typography the punctuation mark comma is a downward short stroke from right to left (/).

COMMA BACILLUS. See CHOLERA.

COMMAGENE, kŏm-a-jē'nē, in ancient times a district in the north of Syria, bounded on the east by the Euphrates, on the north by Mount Amanus and on the west by Cilicia, for some time attached to the kingdom of the Seleucidæ, but afterward for more than 100 years an independent state. It seems to have become independent about 100 B.C., and on the death of its fifth king, Antiochus III, in 17 A.D., it was made a Roman province. It was again for a time allowed by the Romans to hold a position of nominal independence, but was reduced to a Roman province by Vespasian, 73 A.D.

COMMANDER-IN-CHIEF, the supreme commander of the united forces of any country. In the United States the President is commander-in-chief of the army and navy, and of the militia of the several States when the latter is in the national service and forms part of the national provisional army. In all other cases the governor of each State is the commander-in-chief of the State troops. In England he is officially called the officer commanding-in-chief. He is the head of a department of the military administration. He acts, under the Secretary of State for War, as the head of the army, and when military operations are undertaken on a sufficiently large scale to require his presence, is charged with the duty of commanding the army in the field, though, as a matter of fact, this very rarely occurs. In Germany the president is the supreme commander-in-chief of the army and navy. The chief of staff of the French navy is commander-in-chief designate for war purposes. The French army is in the ministry of war, which may be assisted by the Council of marshals and generals in matters of strategy or policy. In Great Britain the title of commander-in-chief of his majesty's forces was abolished in 1904; since which date there has been no holder, in deputy, of the once regal title of commander of the forces on land and sea of the nation. The Secretary of State for War is now responsible to the Crown and Parliament for the conduct of military affairs.

COMMANDER OF THE FAITHFUL, a title assumed by the Caliph Omar, father-in-law of Mohammed, and retained by his successors. See CALIPH.

COMMANDER ISLANDS, two islands belonging to Russia lying east of Kamchatka in Bering Sea. The larger, Bering Island (q.v.), lies nearest the coast; the other island of the group, Miedni, is nearly 30 miles long but narrow; it is sometimes called Copper Island, because copper is found there in small quantities. The climate is mild and there are few inhabitants.

COMMANDERY. (1) Among the Knights Templar, Hospitallers, etc., a district under the administration and control of a member of the order, called the commander or preceptor, who received the income of the estates within that district, expending part for his own use and accounting for the rest. In England more especially applied to a manor belonging to the Knights Hospitallers or Knights of Saint John of Jerusalem. These establishments formed at the same time branches. On the first creation of these (branch) establishments they were denominated Preceptories, the superior being called the preceptor; but eventually the name became changed to that of commandery by which they were always afterward known. The council reserved to themselves the power of at any time recalling a commander from his post and substituting another in his place, he being merely considered as the steward of their property. Time, however, gradually wrought a great change in the relative position which the commanders held to the council; and, eventually, a nomination to a commandery came to be considered in the light of a legal acquisition, subject only to the payment of a certain amount of annual tribute to the public treasury, which tribute received the name of Responsions. (2) A regular assembly of Knights Templar, which confers certain degrees. Consult 'History of Knights of Malta.'

COMMANDING OFFICER. (1) In military service, the senior officer of a regiment, corps, post or detachment, where there is no higher local authority, is regarded as the commanding officer. (2) The officer in actual command of a vessel of war. He is an officer of the executive corps and is usually addressed by the courtesy title of "captain" without regard to actual rank, provided he is permanently in command and not in charge temporarily during the absence of a senior. The commanding officer of a modern battleship is responsible for the safety of ship and crew and for the proper care of batteries, engines and other machinery.

COMMANDITE, kŏm-mŏn-dēt', **En,** a term used in France, primarily for a partnership or firm, in which one advances the funds, while another devotes his skill and assiduity; but by extension, a copartnership en commandite oftener means a company for manufacturing or trading, "with limited liability." In terms of French commercial law, those whom we would call the sleeping partners or silent partners in such associations are denominated commanditaires. Their names do not appear in the nominal title of the firm; they may assist it with their counsel, but they cannot order or sign for its benefit, nor act overtly for it in any way; on the other hand, they are not bound to incur a final loss in case of its failure, beyond that of the entire sum they have advanced, should indeed such be needed to satisfy the claims of agents and creditors. For all details on the rights and obligations of commanditaires, consult the French 'Code de Commerce,' articles 23–28.

COMMELIN, kŏm-lăn', **Hieronymus,** hī-ē-rŏn'ĭ-mŭs. See COMMELIN, JEROME.

COMMELIN, Isaac, Dutch historian: b. Amsterdam 1598; d. there 1676. Among his works the history and description of Amsterdam is still much valued.

COMMELIN, Jan, yän, Dutch botanist: b. Amsterdam 1629; d. 1692. He was for many years a professor of botany in the university of his native city, where with his nephew, Casper, he founded the botanical gardens renowned throughout Europe. He wrote much on horticultural subjects in Latin, the inspiration in some cases being his interest in these gardens over which he exercised a fatherly care.

COMMELIN, Jerome, Flemish printer: b. Douay; d. Heidelberg 1598. He was distinguished by his excellent editions of Greek and Latin classics. His emblem is a figure of Truth, and on many editions the words *Ex Officina Sanct. Andreana.*

COMMELINA, kŏm-mĕ-lī'na, or dayflower, is a genus of the spiderwort family (*Commelinaceæ*). It contains about 100 species widely distributed in warm and temperate zones. There are about eight species found in the United States, along streams and in waste places, from Massachusetts to Missouri, southward to Florida and Arizona. The fleshy rhizomes of some species may be eaten when cooked, as they contain much starch and mucilage. In Asiatic countries some are used for medicinal purposes. The plant receives its name from Jan and Casper Commelin, two noted Dutch botanists.

COMMEMORATION ODE. The 'Ode Recited at the Harvard Commemoration' was delivered by James Russell Lowell, 21 July 1865, at the laying of the cornerstone of Memorial Hall, Harvard, and the exercises in honor of the sons of the college who had died in the war for the Union. The choice of a poet for the occasion was a fitting one, for Lowell was a devoted Harvard man, and had suffered serious personal bereavements as a result of the war. In its present form the 'Ode' consists of 12 strophes, but the sixth strophe, on Lincoln, was written after the rest of the poem had been delivered. It sustains a high tone throughout, though there is a certain unevenness which may in part be accounted for by the author's habits of work. While by no means intellectually indolent Lowell was accustomed to postpone the task of actual composition as long as possible, and he was never very successful in revision. In this case he did not begin to write until within 48 hours before the poem was to be delivered, and, except for the addition of the strophe referred to, later changes were not important. From its nature the 'Ode' could show none of the rollicking humor of the 'Fable for Critics' and none of the clever satire of the 'Biglow Papers,' and it lacks something of the youthful energy and enthusiasm that accompanies the idealism of the 'Present Crisis' and the 'Vision of Sir Launfal.' But if it does not show these distinctive characteristics of the author, it is the best expression of Lowell, the

dignified scholar and patriot, and as such some of his admirers have ranked it as his best work. Among the finer passages are the tribute to Lincoln, and the third strophe, beginning "Many loved Truth."

WILLIAM B. CAIRNS.

COMMENCEMENT. In the colleges of the United States this term denotes the day when the students receive the various degrees. The bachelor and master degrees and the degrees of doctors in the professions are conferred at such a time. The term is given also to the closing exercises of secondary and even elementary schools. The commencement custom is a very old one. Originally it was really a commencement or inception, for the term meant, not the beginning or commencement of a school or term, but the inception of the pupil graduate as a teacher and his recognition as such by his master and other members of the profession. He at once entered upon the duties of his new work; so in this sense the ceremony signified a commencement.

COMMENDAM, kŏm-mĕn'dăm (Lat. *commendare,* that is, to intrust), used in ecclesiastic law to denote the administrative or provisional management of a benefice during a vacancy. The person entrusted with the management is called *commendator.* The grant or benefice was sometimes converted into a regular fief and was then said to be in *perpetuam commendam.* The practice gave rise to great abuses, and is now almost unknown.

COMMENSALISM, the intimate connection or partnership between animals of quite different affinities; thus commensals, messmates, or fellow-boarders take up their abode together for their mutual benefit. A good example is a large sponge, whose canals and passages shelter innumerable worms, crustacea, etc., which lodge there without expense to their host. Floating jellyfish shelter certain pelagic crustaceans (*Hyperina*) and little fishes. The oyster-crab (*Pinnotheres*) is a typical case of commensalism; it does no harm to the oyster or mussel in whose shell it lives, and which protects it from danger; while, as the result of its sheltered life, its shell is soft and thin. The pearl-oyster, besides taking in a *Pinnotheres* as a boarder, admits a kind of shrimp. Certain small slender, eel-like fishes (*Fierasfer*) insinuate themselves into the body of holothurians, which also keeps open house for *Pinnotheres* and shrimps; hence a holothurian has been compared to a hotel with its *table d'hôte.* Other crustaceans board in different animals; thus a little crab (*Fabia chilensis*) lodges in the end of the intestine of a sea-urchin; another (*Porcellana*) lives on the Brazilian coast in a starfish. Polyps and corals shelter various species of crabs, snails, etc., all being of the same color, while a crinoid (*Comatula*) takes in as a permanent lodger a decapod crustacean (*Galathea*). Hermit crabs, taking up their abode in an empty snail-shell, are obliged to admit a variety of intruders who come to stay. Certain mollusks live in starfishes and other echinoderms and, as the result of their semi-parasitic life, become more or less modified and degenerate. Thus *Stylina* lives on a crinoid (*Comatala*); a species of *Stilifer* becomes encysted on the rays of a starfish (*Linckia*), and on the underside of the arms of the same *Linckia* lives a limpet-like snail (*Thyca*), while *S. astericola* lives in the body of a Bornean starfish, and so on with a number of similar cases. Ascidians throw their "front hall" (*atrium*) wide open to a variety of forms, such as small worms, polyps, mollusks, crustaceans of different orders, sea-spiders, brittle-stars. The "Venus flower-basket," a silicious sponge of the Philippine Islands, gives shelter to three different kinds of crustaceans: a prawn, a *Pinnotheres* and an isopod.

Rising to the higher animals there occurs on an island off the New Zealand coast the case of the interesting lizard "tuatara," which shares its deep burrows with a petrel, though the latter may at times be the work of the bird. Each builds its nest on opposite sides of the chamber, the lizard almost invariably choosing the right and the petrel the left side. The former sits with its head close to the entrance ready for any attack; it feeds partly on worms and beetles, and in part on the remains of fishes and crustaceans brought to their common table by the petrel.

By far the most numerous assemblage of messmates are the different kinds of beetles and other insects which live in ants' nests, the number of kinds of which amount to upward of 1,500. See ANT; COCKROACH; SYMBIOSIS.

COMMENSURABLE, among geometricians, an appellation given to such quantities or magnitudes as can be measured by one and the same common measure. Commensurable numbers, whether integers or fractions, are such as can be measured or divided by some other number without any remainder; such are 12 and 18, as being measured by six or three. Magnitudes having no common measure are said to be incommensurable. Thus the diameter and the circumference of a circle are incommensurable as are also the diagonal and side of a square. The word commensurable has also another sense. Numbers like $\sqrt{2}$ which are not commensurable with ordinary rational numbers are said to be incommensurable.

COMMENTARY, a term used (1) in the same sense as memoirs, for a narrative of particular transactions or events, as the 'Commentaries' of Cæsar. (2) A series or collection of comments or annotations. These may either be in the form of detached notes, or may be embodied in a series of remarks written and printed in a connected form.

COMMENTRY, kō-măn-trē, a town in central France, in the department of Allier, eight miles southeast of Montluçon, in the midst of a vast coal field. Pop. 11,280.

COMMERCE, Ga., city in Jackson County; 18m. N. of Athens; on the Southern Railway. It has cottonseed oil mills and an overall factory. Pop. (1940) 3,294.

COMMERCE, Okla., city in Ottawa County; 4m. N. of Miami; on Northeast Oklahoma (electric) Railroad; zinc and lead mining. Pop. (1940) 2,422.

COMMERCE, Texas, city in Hunt County; alt. 548 feet; 98m. NE. of Fort Worth; on the St. Louis Southwestern and Southern Pacific railroads. It is a shipping center. East Texas State Teachers College is here. Pop. (1940) 4,699.

COMMERCE, Chambers of. See CHAMBERS OF COMMERCE.

COMMERCE, Department of. The Department of Commerce is one of 10 such departments in the executive branch of the federal government under the direction of a secretary who is appointed by the President of the United States and who also serves as a member of his Cabinet.

The record of events from the close of the Revolution to the Constitutional Convention at Philadelphia in 1787 reveals that there was a strong desire to foster the commerce and trade of the states. During this period Washington, Hamilton, Madison, and others actively participated in various public conventions where their efforts were devoted to encouraging interstate commerce. Finally Gouverneur Morris, at the Constitutional Convention, submitted a proposal «that there should be . . . a Secretary of Commerce and Finance» whose duties, in part, should be to «recommend such things as may in his judgment promote the commercial interests of the United States.» However, the head of this proposed department was designated as Secretary of the Treasury.

It may appear strange that 116 years elapsed before a Department of Commerce became a reality, although its need was recognized at the very beginning. The tendency of the national legislature to follow and not lead in enlarging the executive side of the government compelled the Department of Commerce to wait, as each of the older departments in their turn had waited, until the demand for the legislation became paramount and unanimous, and until the field of its activity was already so large and the appeal so urgent that none but an affirmative answer could be given.

The Department Established.—It remained for the 57th Congress, by the act of 14 Feb. 1903 (32 Stat. 826), to establish the Department of Commerce and Labor. The first organization of the department consisted of the following services, most of which had existed in other government departments or as independent agencies: Bureau of Lighthouses, Steamboat Inspection Service, Bureau of Navigation, Bureau of Standards, Coast and Geodetic Survey, Bureau of Immigration, Bureau of Statistics, Bureau of the Census, Bureau of Fisheries, Bureau of Labor, Bureau of Manufactures, and the Bureau of Corporations. In 1912 the Bureau of Foreign and Domestic Commerce was established by the consolidation of the Bureau of Manufactures and the Bureau of Statistics. The Children's Bureau was formed also the same year.

In 1913, the Bureau of Immigration, the Children's Bureau, and the Bureau of Labor were transferred to the newly created Department of Labor, and the Department of Commerce and Labor became the Department of Commerce. Since 1913, several new agencies have been added, some of which have grown to independent status, and others incorporated with departments more closely allied with their functions.

In 1914, with the establishment of the Federal Trade Commission, the Bureau of Corporations was abolished. The American patent system under the Patent Office was incorporated into the Department of Commerce in 1925. In the same year the Bureau of Mines became incorporated in the Commerce Department. To carry out the provisions of the Air Commerce Act of 1926, an agency was established in the department, first designated as the Aeronautics Branch but later known as the Bureau of Air Commerce, to aid in the promotion and development of civil aeronautics.

The Radio Division which since 1910 had functioned as a part of the Bureau of Navigation was made a separate agency in the department in 1927, and in 1932 became the independent Federal Radio Commission (now Federal Communications Commission). On 30 June 1932, the Bureau of Navigation and Steamboat Inspection Service were consolidated and became known as the Bureau of Marine Inspection and Navigation. On 22 Feb. 1934, the Bureau of Mines was transferred to the Department of the Interior. By the terms of the Merchant Marine Act of 1936, all shipping activities of the Commerce Department were transferred to the United States Maritime Commission. Under the Civil Aeronautics Act of 1938, the activities of the Bureau of Air Commerce were carried on independently as the Civil Aeronautics Authority.

Effective 1 July 1939, the Bureau of Lighthouses was transferred to and consolidated with the Coast Guard, the Bureau of Fisheries was transferred to the Interior Department, and the Inland Waterways Corporation, a self-supporting corporation of the United States was transferred from the War Department to the Department of Commerce.

By the provisions of Reorganization Plan IV, effective 30 June 1940, the Civil Aeronautics Authority was reorganized. The economic, safety, and regulatory features were established in the Civil Aeronautics Board, which remained an independent agency, but submitting its reports to the President and to the Congress through the Secretary of Commerce. The remaining functions of the authority were vested in the Department of Commerce under the Civil Aeronautics Administration. Under the same reorganization plan, the Weather Bureau was transferred from the Department of Agriculture to the Department of Commerce. By the authority of the First War Powers Act, 1941, the functions of the Bureau of Marine Inspection and Navigation were transferred to the Bureau of Customs (Treasury Department), and to the United States Coast Guard (Navy Department), for the duration of the war. Effective 24 Feb. 1942, by Executive Order 9071, issued pursuant to the First War Powers Act, 1941, the functions, powers, and duties of the Federal Loan Agency and of the Federal Loan Administrator, duties not transferred by the executive order establishing the National Housing Agency, were transferred to the Department of Commerce, to be administered under the direction and supervision of the Secretary of Commerce.

Organization.—The Department of Commerce as at present (1944) constituted, in addition to the offices and divisions in the immediate Office of the Secretary, consists of the Bureau of the Census, Civil Aeronautics Administration, Coast and Geodetic Survey, Bureau of Foreign and Domestic Commerce, Inland Waterways Corporation, Patent Office, National Bureau of Standards, and Weather Bureau. Also under the Secretary of Commerce is the National

Inventors Council. Created in 1940, its purpose is to receive, evaluate, and pass on to the appropriate branches of the armed services all inventions, inventive ideas, and processes submitted by the public as a contribution to the war effort.

The Secretary of Commerce, whose term of office is the same as other Cabinet officers, is assisted by an Under Secretary, Assistant Secretary, Administrative Assistant to the Secretary and other assistants to the Secretary.

Purposes and Activities of the Department.—The Department of Commerce is preeminently concerned with the nation's business. It is the duty of the department to foster, promote, and develop trade and industry. Its services are designed to simplify processes, increase and improve production and eliminate waste in production and distribution.

The activities to assist in these purposes include population, agricultural, and other censuses; collection, analysis, and dissemination of commercial statistics; promotion of foreign and domestic commerce; coastal and geodetic surveys; establishment of commodity weights; measures, and standards; supervision of the issuance of patents and the registration of trademarks; the establishment and maintenance of aids to air navigation, the certification of rules and regulations issued pursuant to the Civil Aeronautics Act of 1938; supervision of the issuance of weather forecasts and warnings for the benefit of agriculture, commerce, and navigation, including weather service for aviation, and the publication of climatic statistics; and the development of inland waterway transportation.

During American participation in the Second World War the peacetime activities of the Department of Commerce were greatly curtailed or discontinued and the department's bureaus and services were employed almost entirely in the war effort.

For further information on the department's various services and bureaus, see articles under separate headings.

MALCOLM KERLIN,
Administrative Assistant to the Secretary of Commerce.

COMMERCE, History of. Commerce, the exchange or buying and selling of commodities, is essentially the result of a division of labor. By it man assigns, unconsciously in some instances, the production of certain articles to certain areas in which they can be most conveniently or most economically or most profitably produced, and other articles to other areas or groups of people.

The history of commerce divides itself into three great periods. The first is that in which merchandise was transported by men and animals on land and in vessels sailing along the coasts and seldom venturing out of sight of land; the second began when man learned the use of the compass and traversed the great ocean, but by sailing vessels only. The third began when he applied steam power to the movement of vessels on the ocean and vehicles on land, and this period was simultaneous with that of the establishment of instantaneous communication by the use of electricity.

These three periods vary greatly in length. The first period, that of the sailing vessel creeping along the shores or crossing narrow seas by the observation of the heavens, extends from the earliest period of history down to about the year 1300. The second, that of the sailing vessel guided by the compass, extends from about 1300 to 1819, when the first steam vessel crossed the ocean. The third, that of steam and motor transportation by sea and land and instantaneous intercommunication by electricity are all included within the last 125 years. These three periods, of course, greatly overlap one another. The period of the sailing vessel, guided by the observation of the shores or the sun and stars, merged almost insensibly into that in which vessels were guided by the use of the compass, and no exact date can be named as that of the transfer. The compass was known as early as the year 1300 but it took more than a century so to develop its practical use as to lead man to the exploration of the great oceans which he had always looked upon as a barrier to travel or exploration; nor can it be said that the transition from the sailing to the steam vessel occurred at a fixed date, for it took 20 years after the first steam vessel crossed the ocean to establish even a limited transatlantic service, and for many years thereafter a large part of the commerce was carried by sailing vessels. The construction of railways, a part of the third period, occupied many years of time and experimental work. The telegraph and ocean cable, the telephone and wireless telegraphy, which are important factors in the third period, and the later internal combustion engine, were a development which greatly multiplied the commerce demanding the services of water transport and railways.

In the first period commerce centered in the Mediterranean and extended over western Europe, northern Africa and western Asia. In the second period, when the use of the compass encouraged man to explore the oceans, the Atlantic was crossed in 1492, India reached in 1496, China in 1516, and the first voyage around the world made in the period 1519–22. Yet with these long experiences of the sailing vessel, 3,000 years of the first period and 500 years of the second, the entire international trade of the world, when the period of steam began 125 years ago, was but $1,500,000,000, and today is $45,000,000,000. Thirty-five hundred years of the sailing vessel on the oceans and animal transportation on land had developed but $1,500,000,000 of international trade, then, with the advent of steam and electricity 100 years brought the total to $45,000,000,000, or 30 times as much in 100 years as had been developed in 3,500 years without steam and electricity.

The exchanges between nations and peoples have always been governed by certain great natural laws. Tropical products have always been wanted by temperate zone men, and temperate zone products are wanted by the people of the tropics. Also, the people of the older and more densely populated areas demand the food and other natural products of the more recently developed regions and the newly developed areas demand the manufactures and luxuries of the older communities. Densely populated Europe buys the foodstuffs and manufacturing materials of the more newly developed continents, North America, South America, Asia and Oceania, and these newly developed areas take the manufactures of Europe in exchange for their natural products. This is the division of labor among the world population, accomplished by commerce.

The earliest records of commerce between great groups of people relate to the exchanges between Egypt and Mesopotamia 4,000 years ago. The Egyptians were chiefly an agricultural people, while those of the Mesopotamia Valley, although agricultural, had developed certain manufacturing industries, and drew other manufactures from India, and perhaps China, and also certain temperate zone products from the upper waters of the Tigris and Euphrates. So, there grew up limited trading between the two valleys, carried across the desert by the caravans of the Arabs, chiefly the silks, precious stones, spices and gems of the Orient, exchanged for the cotton and flax and cattle and food grains of Egypt. The Phœnicians, a Semitic race closely allied to the Hebrews, removed about this time from the Persian Gulf to the eastern end of the Mediterranean, and slowly built up a carrying trade along its shores, their vessels first propelled by oars, but later by sails. Gradually they extended their operations along the shores of the Mediterranean, passing through the Bosporus into the Black Sea, and also pushing westward along the northern shore of Africa, and even in a limited way along the western coast of Europe as far north as the British Isles and the Baltic. They built great cities, Tyre, Sidon and Carthage, established manufacturing industries and became the great traders of the world during a very long period, bringing the temperate zone products of the Baltic Sea region and of northeastern Europe, wool, furs, grain, tin and copper and silver, and exchanging them for the semi-tropical products of the Mediterranean countries and Euphrates Valley and the manufactures of their own great cities. Of course it took hundreds of years to develop these cities and their manufacturing industries and build up the commerce with the great frontage stretching from the Baltic Sea along both sides of the Mediterranean and the western coast of Europe, and the Phœnicians were the great trading people of the world for more than 1,000 years.

Gradually, however, the Greeks, who from their homes nearby witnessed the successes of the Phœnicians, followed in their footsteps, Athens and Corinth became manufacturing and commercial cities, and Greek vessels and merchants entered upon the trade of the same area in which the Phœnicians had been so successful. The conquests of Alexander, which extended to Persia and India, also aided Greek commerce by the views which they disclosed of Oriental civilization and the increased use of money in commerce, just as the experiences of the Crusaders in the same area did for Western Europe many generations later. The Greeks, however, did not develop as successful commercial qualities as did the Phœnicians, and the period of their control of world commerce was much shorter. The Romans succeeded the Greeks, as they extended their political control over an area nearly as great as the present United States, and with a population nearly as big as our own at the present time, stretching from the Euphrates valley on the east to northern Europe, and including both frontages of the Mediterranean. They built up great fleets of commercial vessels, developed roads and commercial routes throughout their colonies, and Rome became the great centre of their enormous area. The natural products of northern and western Europe and the manufactures and luxuries of the Orient supplied the demands of that great and luxurious city of more than 1,000,000 inhabitants. The decline of the Roman power reduced this commerce very greatly, though that with the East was somewhat revived by the transfer by Constantine of the seat of government to Byzantium (Constantinople) (Istanbul).

The development of the Mohammedan Empire in the 7th century A.D. made great changes in the commercial world. The Mohammedan religion favored commerce, and as its followers occupied most of the Mediterranean shore the effect upon commerce and industries was very great. Damascus, Bagdad, Alexandria, Cairo and the cities of Spain became great centres of industry and trade, and the people of the Christian world learned from the Mohammedans many important lessons of industry and traffic. Even the Crusades, which were organized military movements against the Mohammedans in the Holy Land, taught the people of western Europe many valuable lessons in manufacturing through the opportunities thus offered to the Europeans of observing the superior industries of the Mohammedan world, in manner similar to that resulting from Alexander's invasions of the Orient, and these lessons resulted in the development of manufacturing industries in western Europe.

During the long period extending from the fall of the Western Roman Empire to the application of the compass to ocean navigation, the period which is usually designated as the Middle Ages, new trade routes and commercial centres were developed. Venice and other Italian cities became great trading and manufacturing centres, sending their ships to the eastern end of the Mediterranean and the Baltic Sea for the Oriental products of tropical Asia and the grains and wool of the Baltic Sea frontage, redistributing them with their own manufactures to northern and western Europe by land routes and coasting vessels and bringing back the woolens and linens and leather and other products of France and Great Britain and Germany and the Low Countries. Again it was the exchange of the products of different climatic areas and different civilizations. Venice became a great manufacturing, commercial and financial centre and sent its manufactures to Asia Minor, northern Africa and northern and western Europe. Its vessels were numbered by thousands, yet their operations were confined to the inland seas and the Atlantic Coast. It sent its consuls to report upon conditions of the countries with which it traded, built up a great banking and credit system with branch banks in these countries, and its example was followed by other Italian cities, especially Genoa and Florence. These commercial activities of the Italian cities developed trading stations and cities in northern Europe. Antwerp, Amsterdam, London, Cologne, Hamburg and Lubeck became active commercial centres, while fairs and markets were built up along the routes over which this merchandise was carried, developing into trading towns and cities.

Commerce during this period of the Middle Ages was, however, subject to constant attack by brigands and petty feudal lords, and as a

result the great trading cities and stations of northern Europe built up organized leagues for the protection of their trade. They supplied armed guards to protect the commerce moving along the land routes, and this facilitated the establishment of new trading stations which developed into towns and cities. The Hanseatic and Rhenish leagues, organized in Germany, included nearly 100 towns in each, and their influence in the protection to and development of trade was very great and was an important influence in developing orderly government and new political governments. Their activities extended over a term of nearly 250 years, and only ended when the use of the compass turned the activities of trade to the oceans, greatly reducing the importance of the Italian cities and the trade systems which they had built up. The commercial and financial activities of this long period, however, developed great commercial, financial, banking and credit systems, as well as organized governments, and fitted western Europe to begin trade with the Americas and eastern Asia when the application of the compass to ocean navigation revolutionized trade routes and commercial methods.

The period of the practical application of the compass to ocean navigation began about 1400, although its use was begun in a limited way about the year 1300. The eastern frontages of the Atlantic were explored and the islands off the coast of Africa occupied. Columbus, convinced that the earth was a globe, and that India could be reached by sailing westward, ventured boldly out on the Atlantic, discovering America in 1492. The circumnavigation of Africa and the opening of the route to India occurred in 1496, the extension of the route to China in 1516 and the circumnavigation of the globe 1519–22. This developed new routes of commerce and also the true functions of commerce, the interchange of the products of different climatic areas and different types of civilization, the division of labor among the people of the world. The great masses of Oriental population were found possessed of certain products desired by those of Europe who were able to offer in exchange their own manufactures and the precious metals which they had begun to receive from America. Commerce then became truly international and intercontinental, exchanges between different climatic areas and civilizations. To develop this new form of commerce, the interchange of the products of the various quarters of the entire globe, new facilities were required, and large sums of money demanded, both in the transportation of merchandise and in the financial operations of the exchange. The governments of Europe, stimulated by the prospects of gaining additional territory as well as commercial profits, entered the field. The Spanish, Portuguese, Danish, English and French governments chartered commercial companies for the development of trade and exploration and granted them liberal aid, and at the same time encouraged colonization, especially in America, where there were vast unoccupied areas. The Portuguese sent their trading ships around Africa and established a trading station at Goa, on the coast of India, and the commerce was conducted under the direction of the government, but open to all Portuguese. Spain explored and conquered Mexico and the western coast of South America, and established commerce with those areas, with squadrons escorted by ships of war. Merchandise was sold to the natives and colonists, and large quantities of gold and silver transferred to Europe, stimulating manufactures and proving extremely useful in the trade with the Orient. The English, who had been buying quantities of Oriental merchandise from the Portuguese, were excluded from that market by the Spanish government, and so established the great East India Company in the year 1600. It developed important trading relations with the Indies and later with China, and with the co-operation of the government extended its control over parts of India, laying the foundations for the occupation of that country by the British. The Dutch also excluded from their large trade with the Portuguese, established the Dutch East India Company in 1602 and sent their ships to the Orient, taking possession of Java and developing a very large business in Oriental products, especially spices which were extremely popular in Europe at that time. Their business was highly successful and Holland became a great commercial, financial and banking country. The French government also established an East India trading company, also one for the West Indies, but they were less successful than those of Great Britain and Holland.

These great commercial companies, chartered by their respective governments, were not only traders but explorers and colonizers as well, especially those operating in America, while those operating in the Orient established trading stations and by obtaining concessions from the native governments gained control of important areas. The colonies and trading stations thus established contributed greatly to the advantage of the mother country, both by their contributions of needed supplies and by the market they furnished for manufactures. As a result of the desire to develop the production of the tropical areas, especially in America, the African slave trade was built up, multiplying the production of the colonies, in the New World, and only terminating with the American Civil War. The application of the compass to navigation had a profound effect upon world commerce. Prior to that time most of the international trade was the exchange of the products of the near East and the subtropical Mediterranean area for those of northern and western Europe, a limited exchange of the products of the different climatic products and civilizations. But with the extension of the transportation and trade to every part of the world, and the development of the producing power of the new countries the exchanges between different civilizations, climatic areas and manufacturing communities was greatly enlarged, and commerce became more than ever a division of labor among great groups of people and great sections of the world.

The transition from the sail on the ocean and animal power on land to steam vessels on the ocean and the railway on land was not accomplished in a single year or decade. The first steam vessel crossed the ocean in 1819, and another from England to India in 1825, but it was not until 1838 that successful trans-Atlantic steam service was established

All of these vessels were propelled by the paddle wheel, which proved unsatisfactory for ocean service, and in about 1845 the screw propeller was introduced and soon displaced the paddle wheel. Iron began to be substituted for wood for the construction of vessels about 1850, and steel for iron about 1865. The engines used by the vessels were at first very simple and unsatisfactory, and it was not until 1864 that the compound engine was adapted to marine use, the triple-expansion engine in 1874, and turbines and internal combustion engines later. By these improvements the speed and carrying power of vessels was quadrupled. A single steamship of to-day will carry 600 modern carloads of ordinary merchandise. The result of this development of the steamship is that the tonnage of the sailing vessels of the world is now but about one-ninth that of 1860, while that of steam and motor vessels is nearly 40 times increased, and when we remember that the average steamship will, by reason of its greater speed and more complete control in all kinds of weather, make four times as many trips over a given course in a year as the sailing vessel we begin to realize the enormous expansion of the carrying power which came with the ocean steamer. The growth of the railway on land was an equally important factor in the development of the third period, and so was that of the telegraph. The railways of the world were but 24,000 miles in 1850, now they are 777,000 miles, or 32 times as much, and their carrying capacity per mile is probably four times as much as then, due to the improvement of roadbeds, the change from iron to heavy steel rails, double and quadruple tracks, stronger, larger and faster engines and larger and better cars. They have made possible the transportation of merchandise from the interior of the continents to the water's edge, and this fact has stimulated the development of population in the interior. The population of the interior of the United States, for instance, has trebled since 1870, and the value of its products increased from $2,000,000,000 to $20,000,000,000. World population, which was but 650,000,000 in 1818, grew to 1,962,000,000 in 1928, due in part to the opening of new areas to population, and in part to the practicability of increasing the density of population at any point and transporting from other parts of the world the food which is required.

Instantaneous communication has also contributed greatly to the growth of commerce in the latest period. The land and ocean telegraphs in 1850 aggregated but 5,000 miles and to-day are more than 7,000,000 miles, with greatly increased facility of transmission per mile, and even this wonderful system has been greatly intensified by the telephone and wireless telegraph. The fact is the business man or producer in any part of the world can now speak instantly to the business man in any other part of the world, on the other side of the globe, in the interior of the continent and even to the vessels in the midst of the oceans, and may also transmit funds by the same instantaneous process, if desired. The motor car, airplane and radio have further shortened the distance and time factors.

Finance has also participated largely in this growth of commerce in recent years. The world's production of gold prior to 1850 was less than $10,000,000 a year; in 1915 it reached the high-water mark of $470,026,251. The quantity of gold mined in the short period since 1870 is twice as much as in the 400 years prior to 1870. This enormous increase in the quantity of the world's accepted medium of exchange has greatly aided the growth of commerce, while the development of the banking and credit systems has been quite as important. The banking power of the world, by which we of course

WORLD'S DEVELOPMENT OF POPULATION, PRODUCTION, VESSEL TONNAGE AND COMMERCE

[1] Figures for period 1493–1885 are Dr. Adolph Soetbeer's averages; for years since, figures are the annual estimates of the United States Bureau of the Mint.

[2] At the average par price of a fine ounce of silver in London, excepting for the years 1918–22, inclusive, for which the mean of the New York bid and asked prices was used. [3] Includes 1931–36 production.

mean capital, surplus, deposits and circulation, has grown from approximately $8,000,000,000 in 1870 to $80,000,000,000 at the present time, and credits have expanded with an equal rapidity.

It is for these reasons that the third period of world commerce, that of steam, electricity and finance, has been one of unparalleled developments. In the first period, extending over thousands of years of the sailing vessel without the compass, in which the oceans were considered a barrier to commerce or exploration, the world trade in an entire year was less than that of a single day at the present time. In the second period, that of the sailing vessel and compass, covering about 500 years, in which man traversed the globe by sailing vessels only, he built up world commerce to $1,500,000,000 a year. In the third period, which has covered but 100 years, he has developed a trade of $68,000,000,000 per annum, or 50 times as great as he had been able to create in 3,500 years without the aid of steam, electricity and modern finance. International commerce at the beginning of the third period averaged about $2 per capita for the entire world population; in 1929 it was nearly $35 per capita for the greatly increased population. In this last period of growth the same principles of a division of labor among the people of the earth, the exchange of the products of certain peoples and areas and climates for the different products of other areas and peoples and climates stand out more clearly than in the earlier periods. Manufacturing Europe buys food and manufacturing materials from the other continents and pays for them in manufactures; the United States draws upon the tropics and Orient for manufacturing material and certain foodstuffs and pays for them with the product of her factories; Asia exports her silk and tea and fibres to Europe and the United States and takes manufactures in exchange; South America and Oceania sell their foodstuffs and raw material to the United States and Europe and take the product of their factories; and Africa sells gold and diamonds and ostrich feathers and high grade cotton and buys manufactures from Europe and America. Everywhere it is the exchange of the products natural to the area in which they are produced for the natural products of some other area and people, and thus the division of labor becomes more and more sharply defined with the enlargement of transportation, intercommunication and finance.

OSCAR P. AUSTIN,
Statistician, New York.

COMMERCE, Internal, of the United States. The internal or domestic commerce of a country is the exchange of goods or other items of value among the people of the country. The external or foreign commerce is the exchange of goods or items of value between the people of one country with those of another. The statistical data of internal commerce serve to indicate the nature and extent of the industrial and commercial activity of a nation and of the various parts of the country. The data of present periods, when studied in comparison with those for past periods, serve to indicate the progress or retrogression of the economic activity of the country or of various parts of the country if the statistical data for the sections of the country are analyzed. In like manner, comparisons of the data of the nature and extent of the commerce of different countries of the world serve to reflect the existing state of the development of commercial intercourse in these countries, and comparisons of data for present and past periods serve to show the relative progress of commercial activity in different countries. It should be borne in mind constantly that statistical comparisons of quantity or value are valid to show just what they purport to reveal and no more; quantity figures alone do not indicate the monetary value of the products, so that an increase in quantity production alone does not indicate commercial progress because the increased quantities may be exchanged at low prices. Value data alone do not indicate prosperity, since they may show increased monetary prices but no increased quantity. Both quantity and value data are yardsticks, however, and as such are significant. A comprehensive knowledge of the internal commerce of the United States requires the analysis of data pertaining to: (1) the volume and value of all articles and other items of value produced and exchanged; (2) the volume and value of all commodities and items of value manufactured or processed, and the number of times the goods were subjected to manufacturing or processing, as well as the increase in price or value resulting from these operations; (3) the volume of goods transported by all agencies of transportation—railroads, railway express, motor and highway, pipeline, airway, water carriers, and all others—and the value added by the transportatioin services; and (4) the number of times goods are bought and sold by brokers, factors, jobbers, wholesale and retail merchants, and other middlemen, and the increase in price or «value» added by these exchanges, resulting from the costs of doing business and the profits of the middlemen. A simple example suffices to show the many steps and the duplication of the volume and value factors incurred in the course of the production of a single series of transactions, all of which constitute internal commerce. Crude iron ore, mined, let us assume, in Minnesota, appears as a mineral product. It is sold by the mining enterprise to an ore broker, who arranges for its transportation from the mines to a port at the head of navigation on the Great Lakes by railroad. It is sold by the broker to a manufacturer and transported by water carrier to a lower lake port by ore steamship carrier, where it is transshipped by railroad to a smelter. Here, after mixture with limestone and coke, it is converted into pig iron. The pig iron is sold by the manufacturer to a broker or another middleman, who in turn sells it to a rolling mill, where it is manufactured after transportation from the furnace into plates. The plates in turn are sold to a fabricating plant, directly or through a middleman, where the plates are fabricated into finished steel parts. The finished steel parts are sold to a silo manufacturer who erects the fabricated parts into a completed article. This is sold to a wholesale dealer, who in turn sells it to a retail merchant, who sells the finished product to a farmer, who places it in use upon his farm. Between each of these stages of production, fabrication, manufacture, and marketing, transportation services are required, so that the raw materials, semifinished products, and finished articles are not only exchanged but transported a number of times, and appear at different stages in the country's commerce in different forms and at different values.

A fairly accurate statistical picture of the internal commerce of the United States may be had by appraising at intervals the volume and value of the principal commodities or items comprising the domestic trade. By comparing the data for different years, an approximate idea of growth or progress may be had. The same duplication will appear in each of the years studied, so that the figures are comparable. Thus if we can determine at stated intervals the value at the place of production of all articles forming the exchanges among the people, we can approximate the growth from period to period; determine the increase or decrease per capita; and also compare the same with those of other countries. We can even determine the relation which our own internal trade bears to our foreign trade, or to the total international commerce of the world, in so far as these changes can be measured, either in quantative figures or value figures.

The principal articles forming the internal commerce of a country are: (1) products of agriculture; (2) products of the mines; (3) products of forests and fisheries; (4) manufactures produced within the country; and (5) articles imported and sold among the people. All these are measured in a single unit of measurement, the dollar, at the place of production. While the manufactures are, of course, made from the products of such industries as agriculture, mining and forestry, and from certain foreign products, and their use as a basis thus involves a second sale of a part of the already recorded product, the fact that the manufactured article presents this material in an entirely new form seems to justify the inclusion of all manufactures among the five great groups of articles forming the internal commerce of a country: agricultural products, minerals, forest and fishery products, manufactures and imported merchandise.

Agriculture.—Turning first to agricultural commerce, we find that there are 6,812,350 farms in the United States with an area of 1,903,217,000 acres, approximately 55.4 per cent of the area of the United States. The farm population is 31,800,907, representing 25 per cent of the total population of the United States.

Approximately 514,000,000 acres are available for crops. The total acreage devoted to the 45 principal farm crops for 1938 was 341,846,100 acres, and the total value of farm crops was $4,939,725,000 in that year. The value of farm crops cannot accurately be measured unless consideration is given to the value of the crops used in farm home consumption, as well as to the cash income derived from farm products. In 1938, the United States Department of Agriculture reported a farm cash income of $8,020,398,000, including $482,221,000 of government payments—agricultural conservation, rental and benefit, and cotton price and option payments. The home consumption value of farm products in that year amounted to $1,269,660,000, or a gross income for that year of $9,290,058,000. In 1937, the gross income was $10,424,624,000, consisting of cash income of $8,621,474,000, government payments of $366,909,000, and home consumption of $1,436,241,000.

Mineral Products.—The mineral products of the United States produced in 1938 had a grand total approximate value of $4,354,000,000. This amount is divided among the following groups of mineral products: metallic minerals or metals valued at $891,800,000; nonmetallic minerals valued at $3,462,200,000, consisting of fuels (coal, natural gas, natural gasoline, and petroleum, $2,804,700,000); and other nonmetallic minerals, $657,500,000. The comparative value of mineral products may be shown in comparison with previous years:

Year	Grand Total Approximate Value of Mineral Products of the United States.
1880	$ 367,463,000
1890	615,429,000
1900	1,108,936,000
1910	1,987,844,000
1920	6,981,340,000
1930	4,764,800,000
1938	* 4,354,000,000

*Preliminary figure of United States Department of the Interior, Bureau of Mines.

Forest Products.—Products of forests are important items of the commerce of the United States. The total forest resources of the United States in 1938 were estimated at 630,158,000 acres, of which 461,697,000 acres comprise the commercial forest area. The stand of saw timber is estimated at 1,763,651,000,000 board feet—1,493,120,000,000 board feet of soft woods and 270,531,000,000 board feet of hardwoods. The annual growth of wood on commercial forest areas, in 1938, was 5,934,000,000 cubic feet of soft woods and 5,353,000,000 cubic feet of hardwoods, a total of 11,287,000,000 cubic feet.

An aggregate of 13,462,756,000 cubic feet is removed from commercial forests, the lumber equivalent of which is 47,807,677,000 board feet. The total products produced totaled 42,443,374,000 board feet—35,173,862,000 board feet of softwoods and 12,633,815,000 board feet of hardwoods. Valued at an average of $24.25 per 1,000 board feet, the forest products produced had an approximate value of $630,500,000.

Fishing Products.—Fishery products in 1937, the latest available figures, aggregated 4,352,549,000 pounds valued at $100,845,000, including the United States and Alaska. In the fishing industry 129,544 fisherman were employed, and 5,138 fishing vessels and 69,702 fishing boats were used.

Manufactures.—The manufacturing industries in the United States, according to the latest biennial census of manufacturers, of the United States Department of Commerce, Bureau of the Census, turned out products valued at $60,712,871,737 in 1937. The cost of materials, fuel, energy purchased, and contract work was $35,539,332,824, and the value added by manufacture was $25,173,538,913. In 1937, there were 166,794 establishments engaged in manufacturing, employing an average of 8,569,231 wage earners.

Manufacturing industries in the United States are divided into 15 principal groups of industries. The number of establishments, the value of products, and value added by manufacture are shown below:

Group of Industries	Number of Establishments	Approximate Value of Products (000,000 omitted)	Value Added by Manufacture (000,000 omitted)
Food and kindred products	48,727	$11,200	$3,350
Textiles and their products	20,616	7,000	2,900
Forest products	18,012	2,400	1,260
Paper and allied products	3,053	2,000	850
Printing, publishing and allied industries	22,751	2,580	1,790
Chemicals and allied products	7,419	3,700	1,790
Products of petroleum and coal	675	2,900	587
Rubber products	478	880	368
Leather and its manufactures	3,364	1,490	590
Stone, clay and glass products	6,071	1,395	870
Iron and steel and their products (not including machinery)	8,345	7,480	3,400
Nonferrous metals and their products	5,303	2,780	856
Machinery (not including transportation equipment)	9,961	5,890	3,467
Transportation equipment	1,942	5,985	1,886
Miscellaneous industries	10,077	2,700	1,078

Imports and Exports.—The goods imported into the United States from other nations enter into the internal commerce of the United States after arrival at the ports of the United States. It is very difficult to measure the import trade or to compare it with other years because of differences in the gold content of the dollar. The general imports into the United States in 1938 were valued at $1,134,012,000; in 1937, $3,083,668,000; in 1936, $2,422,592,000; and in 1935, $2,047,485,000. The average for the years 1931–35 was $1,713,102,000; for the years 1926–30 it was $4,033,469,000 per year. The volume of import trade will be discussed later when an attempt will be made to estimate the quantitative movement of domestic or internal commerce.

In passing, the value of exports must also be considered in appraising the internal commerce because many items of export commerce appear in the volume and value of goods produced and exchanged before they are sold for export abroad. In 1938 the exports of United States merchandise were valued at $3,057,169,000; in 1937, $3,298,929,000; in 1936, $2,418,969,000; and in 1935, $2,243,081. The averages for the years 1931–35 were $1,998,914,000, and for 1926–30, $4,687,788,000. The volume of exports will likewise be considered later.

The United States has a consistent excess of exports over imports of merchandise. The value

VALUE AT THE PLACE OF PRODUCTION OF ARTICLES FORMING THE INTERNAL COMMERCE OF THE UNITED STATES, 1850 TO 1937

CENSUS YEAR	Manufactures	Farm products	Minerals	Forests, fisheries, etc.	Imports	Total materials of internal commerce	Population	Per capita internal commerce
	Million dollars	*Million dollars* ‡	*Million dollars*	*Million dollars* §	*Million dollars*	*Million dollars*	*Millions*	*Dollars*

* Manufactures and agricultural products reduced to gold basis. † Includes estimate for hand trades and neighborhood industries. ‡ Exclusive of estimated consumption on farms. § Estimated. [1] 1926.

These great groups of merchandise, the manufactures, the agricultural products, the minerals, the products of the forests and fisheries and the merchandise imported, form the internal commerce of the United States, the merchandise exchange between its people, for even that which is finally exported is a part of the internal commerce before exportation.

This grand total of $60,712,000,000, the estimated value of the merchandise forming the internal commerce of the country, represents the products in question at the place of production, and does not make any allowance for the cost added by transportation or the profits of various dealers who handle it between the producer and consumer. Nor does this total of $60,712,000,000 represent more than one sale of the merchandise in question, the original sale by which it passed from the hands of the producer to the markets of the country. How many times it is handled and resold before it reaches the consumer and how much advance he pays upon the price received by the producer, is a matter of conjecture rather than of possible statistical measurement. There are no accepted standards, governmental or otherwise, by which the average number of times that the merchandise is handled or the percentage added to the price at which it is sold by the producer can be determined.

With this basis of measurement of the value at the place of production of the merchandise forming the internal commerce of the United States, it is possible to measure the growth of the merchandise exchanged among her own people from year to year or decade to decade, though the fact that this must be expressed in a single unit of measurement, the dollar, reduces the value of the comparisons since general advances or reductions in prices would show greater fluctuations in the value figures than those in quantities. For purpose of general comparison in measuring the growth of the grand total of all products forming the internal commerce of the country, it is, however, necessary to utilize the single standard applicable to all, the dollar. Accepting the above discussed standards of measurement of the internal commerce of the country, a single measurement at the place of production of all articles forming the internal commerce of the country, we find that the internal commerce of the United States grew from $2,500,000,000 in 1850 to $4,000,000,000 in 1860; $6,000,000,000 in 1870; $9,000,000,000 in 1880; $14,000,000,000 in 1890; $21,000,000,000 in 1900; $34,000,000,000 in 1910; $84,597,000,000 in 1929; and $76,398,000,000 in 1937; a per capita average of $112 in 1850, $128 in 1860, $153 in 1870, $179 in 1880, $222 in 1890, $276 in 1900, $371 in 1910, $715 in 1929 and $568 in 1937, all of these figures being in very round numbers.

The causes of the greater interchange of merchandise among the people of the United States than in other countries lie in part in the large area and great diversity of production in the United States. With an area practically equal to that of Europe, with great mountain regions and long sea frontages, the United States has varying climatic conditions from temperate to subtropical, and consequently a greater variety of products than the smaller countries of Europe. It is because of the fact that the United States by its very bigness and diversity of climate produces such a great variety of products, and has exceptional facilities for their interchange, that we have applied in the United States more fully than elsewhere the great economic law of a division of labor among men and thus made our interchanges greater in proportion to population than is natural to other and smaller countries.

When we compare the value of the merchandise forming the internal commerce of the United States with that forming the international commerce of the world, we begin to realize fully the great volume of our own internal trade. International commerce, as it is usually stated, consists of an aggregation of the imports and exports of all countries of the world. As every article exported is again counted when it becomes an import at destination, it is apparent that this customary aggregation of all the exports and imports of all countries of the world really counts the merchandise twice: first, when exported from the country of production, and again, when imported into the country of consumption. Therefore, the real value of the merchandise forming international trade of the world is but about one-half that of the customary statement of international trade. For example, the international trade of the world in 1913, the year preceding the World War, which may be accepted as a normal year of international trade, aggregated $40,000,000,000. But as this aggregation included all exports plus all imports, it is apparent that the real value of the merchandise, counted when exported and again counted when imported, is

in fact but $20,000,000,000, or one-half of the usual statement of international trade in 1913, $40,000,000,000.

The table which follows shows the aggregate value of exports and imports of all countries of the world, the value of the merchandise forming the international trade, and the value of the merchandise forming the internal commerce of the United States for selected years from 1850 to 1938.

COMPARISON OF INTERNAL COMMERCE OF THE UNITED STATES WITH INTERNATIONAL TRADE OF THE WORLD

	Aggregate value of imports and exports of all countries	Value of merchandise forming international trade of world	Value of merchandise forming internal commerce of United States
1850....	$ 4,050,000,000	$ 2,025,000,000	$ 2,580,000,000
1860....	7,246,000,000	3,623,000,000	3,961,000,000
1870....	10,664,000,000	5,332,000,000	5,973,000,000
1880....	14,760,000,000	7,380,000,000	8,939,000,000
1890....	17,520,000,000	8,760,000,000	13,661,000,000
1900....	20,106,000,000	10,053,000,000	19,914,000,000
1910....	33,634,000,000	16,817,000,000	34,281,000,000
1929....[1]	58,500,000,000[1]	29,750,000,000	84,600,000,000
1937....	29,484,000,000	15,470,000,000	59,139,000,000
1938....[2]	46,600,000,000[3]	27,525,000,000	76,398,000,000

[1] 55 countries. [2] U.S. dollars. [3] Gold dollars.

The fact that the internal commerce of the United States grew more rapidly than the international commerce of the world is accounted for in part by the fact that our population increased practically 500 per cent in the period in question, while that of the world as a whole increased but 75 per cent in the same time.

There are no gateways through which the internal commerce of a country must pass and therefore no governmental or other machinery by which it may be measured in detail. We know that Congress passes laws for the regulation and control of the «commerce between the states» and that we have an Interstate Commerce Commission, yet there is no record, financial or otherwise, of the value of the merchandise passing between the respective states or other divisions of the country, and billions of dollars' worth of merchandise cross and recross state and municipal boundary lines without a record of any sort as to their character, value, the place of production, or final destination.

The table under the title *Progress of United States Shown in Statistics, 1913–39,* showing selected items indicating the quantity and value of the commerce and other items of measurement of material nature, indicates very generally the growth of the national economy of the United States. It should be borne in mind that these figures are only approximate estimates and that differences in the value of money and of goods make simple, direct comparisons impracticable. The approximate progress, in so far as it can be shown statistically, may be noted by comparing the figures for the years shown in the table. The most recent figures for these items can be obtained from governmental statistical organizations which specialize in these studies.

PROGRESS OF UNITED STATES SHOWN IN STATISTICS, 1913–39

(Data 1913–1925 from the National City Bank of New York; data 1937, 1938, and 1939, from various governmental sources)

	1938 (unless noted)	1925	1919	1913
Area (square miles)[1]	3,027,000	3,027,000	3,027,000	3,027,000

G. LLOYD WILSON,
Professor of Transportation and Public Utilities, University of Pennsylvania.

COMMERCE, Interstate. Free trade among the states, unrestricted by trade barriers such as import duties or export taxes, or charges upon the instrumentalities of trade, is provided for by the United States Constitution which forbids the states to «lay any duties or exports» or to «lay any duty upon tonnage.» Congress likewise is denied power to levy taxes or duties upon articles «exported from any state.» The unsatisfactory experience of the states in developing commerce among the states under the Articles of Confederation led to the framing of the provisions of the federal Constitution which prohibited the federal and state governments from levying customs duties or other taxes upon commerce moving from one state to another. These provisions of the Constitution formed, in substance, a free-trade area coextensive with the area of the United States in so far as commerce between the parts of the area are concerned.

Congress was granted by the Constitution exclusive and plenary power to regulate commerce among the states, with foreign nations, and with the Indian tribes. The states were thereby restricted in this activity, and have been restricted in increasing measure as commerce has expanded and become more complex.

At the time of the adoption of the federal Constitution, much of the commerce between states was conducted by water along the Atlantic seaboard and the waterways flowing into the Atlantic or the inland rivers. Roads were few and crude, and the high cost of transporta-

tion made the long-distance movement of low-grade commodities almost prohibitive.

Early Federal and State Regulations.— The predominant importance of the waterborne commerce between the states and the desire to exclude foreign competition led to the passage by Congress of the navigation laws which restricted the domestic trade by water between the states to vessels of American registry, built and owned by American citizens. These laws are the foundation upon which the present-day coastwise, intercoastal, Great Lakes and inland waterway shipping industries are built and the safeguard of these shipping enterprises. Without this legal protection, the domestic waterborne commerce would doubtless have been served by foreign ships because of higher costs of construction and operation of vessels under the American flag.

The importance and scope of the commerce clause of the federal Constitution (Article I, Section 8, paragraph 3), were first duly indicated in the case of *Gibbons* v. *Ogden,* decided by the United States Supreme Court in 1824 (9 Wheat. 1). The Supreme Court in this case decided that commerce included navigation of vessels, the exchange of goods, and all other phases of commercial intercourse. The State of New York had granted an exclusive right of navigation by steam-propelled vessels in its territorial waters, including vessels engaged in commerce between the State of New York and other states, as well as vessels engaged in New York intrastate commerce. The United States Supreme Court, in one of the great opinions delivered by Chief Justice John Marshall, held that Congress had exclusive and plenary power to regulate interstate commerce, and that commerce included navigation. The court held that the monopoly of steamboat navigation in the territorial waters of New York given by the State of New York exceeded the powers of the state and invaded the field of regulation granted by the Constitution to the federal Congress. The power of Congress in this area of regulation was declared to be exclusive and plenary, and the power of Congress to regulate interstate commerce was held to be «complete in itself and may be exercised to its utmost extent, acknowledging no limits other than are prescribed in the Constitution.» This power was held to be plenary because it vested in Congress «as absolutely as it would be in a single government,» and it may be exercised «whenever the subject exists.» «If there is any one object riding over every other in the adoption of the Constitution, it was to keep commercial intercourse among the states free from all invidious and particular restraints. * * * * In all commercial regulations, we are one and the same people.» This monumental decision by the United States Supreme Court laid the foundation of a broad and comprehensive power of the federal government to regulate all interstate and foreign commerce including all aspects and incidents to this commerce, and excluded the states from interfering with interstate commerce.

With the development of steamboat and steamship navigation, it became necessary to inspect the hulls, engines, boilers, and equipment of such vessels, and for the examination and licensure of deck and engine officers engaged in the operation of vessels. This was undertaken by the federal government as a result of acts of Congress applicable to all vessels engaged in the commerce of the United States and to the personnel of the vessels, navigating the navigable waters of the United States, including navigable waters of the United States located wholly within the territorial boundaries of individual states. The power of Congress to so regulate the operation of vessels and the qualifications of those engaged in operating the vessels has been upheld by the United States Supreme Court. These laws are administered now by the Bureau of Marine Inspection and Navigation of the United States Department of Commerce.

The exercise of federal regulatory authority in the field of overland transportation was first exercised in the establishment of postal service. The postal service was established between the colonies along the Atlantic seaboard prior to the Revolution, and was continued as an American national enterprise under the government set up under the Articles of Confederation.

The states, after the Revolution, incorporated transportation companies to operate stagecoaches and wagons over such public roads as then existed, and chartered highway or turnpike companies to construct and operate turnpike or toll roads. The federal government commenced the construction of the Cumberland Road (or National Pike or The National Turnpike) in 1806. This road commenced at Cumberland, Md., and was constructed across Maryland, western Pennsylvania, Ohio, Indiana, and Illinois, reaching Vandalia on the Kaskaskia River, in 1827. It was originally intended to construct the road to Jefferson, Mo., in order to afford a through highway from the Mississippi valley to the Atlantic seaboard. By the time the road had been constructed to Vandalia, the superiority of the railroad for long-distance transportation had become evident. The federal government and the state governments were at odds concerning the federal policy of constructing internal improvements in the territories of the states at this time. For these reasons the National Pike project languished, and was later abandoned.

The need for improved means of inland transportation via roads, rivers, and canals had engaged the attention of some of the leading Americans of the period. In 1772, George Washington directed attention to the need for improving roads, rivers and canals for inland transportation. He advocated the construction of a through route from the Atlantic seaboard to the country west of the Allegheny Mountains and was interested in the promotion of the Chesapeake and Potomac Canal, and other internal improvements. The system of public works of the State of Pennsylvania, consisting of connected stretches of railroad, improved river, artificial canals, and portage railway across the Allegheny Mountains was developed by Pennsylvania as a means of establishing communications between the Eastern seaboard and the Ohio River country. The Erie Canal was constructed by the State of New York to connect the Atlantic seaboard at New York with the Great Lakes via the Hudson River and the artificial waterway afforded by the Erie Canal and the lakes and rivers used as parts of this internal improvement.

In 1866, Congress enacted the first federal

legislation regulating internal overland commerce among the states. The act of 15 June 1866 (31 Stat. L. 1446, ch. 866), provided that «every railroad company in the United States is authorized to carry * * * all passengers, troops, government supplies, mails, freight and property on the way from state to state, and connect with the routes of other states, so as to form continuous lines of transportation of the same to the place of destination.» This act afforded the legal basis for the development of interstate railroads. Many railroads constructed and operated prior to this date were local or intrastate in character. This act gave impetus to their development and expansion beyond state lines.

In the period prior to and immediately subsequent to the Civil War, the political theory of state sovereignty and state's rights resulted in the regulation of railroad transportation and other inland commerce, principally by the state governments. Long before the Civil War, many had organized railroad commissions, or other administrative tribunals, to regulate companies engaged in railroad, and in some instances in other forms of inland transportation. These commissions were, for the most part, of the so-called advisory type. Their powers were visitorial in character, and they depended to a great extent upon the force of public opinion to enforce their orders. After the Civil War, a number of states, particularly those in the Northwest and the Central West—the so-called «Granger» states—enacted severe, and often punitive legislation applying to transportation companies, principally railroads, and to warehouse companies, particularly warehouses used for the storage of grain. These laws provided for strong state regulatory commissions with powers to enforce their orders. There ensued a period of strict and often restrictive regulation of railroads and grain elevators, which is known as the «Granger» period of legislation and regulation, continuing from the close of the Civil War until well into the last quarter of the 19th century. More of this period will be discussed later.

The federal government did not participate in this period of legislation, and it was not until the decision of the Supreme Court of the United States in the so-called Wabash Case in 1886 (*Wabash, St. Louis & Pacific R. Co.* v. *Illinois,* [118 U. S. 557] 1886), that the commerce clause of the federal Constitution was construed to give the federal government jurisdiction over interstate commerce, and to deny to the states power to regulate interstate commerce. As late as 1869, Justice Strong expressed the idea that the commerce clause of the Constitution was framed «as a power to prevent embarrassing restrictions by a state.» (State Freight Tax Case, [15 Wall. 232] 1869). The State of Pennsylvania had placed a tax upon all charges made by railroads for the transportation of freight within the state. Most of this tax was on earnings and not upon commodities carried. No distinction was made in favor of local traffic as contrasted with interstate traffic or commerce. The tax was declared to be a toll on interstate commerce, and its collection was prohibited.

In the Covington Bridge Case, (154 U.S. 204), the establishment of toll rates applicable to transportation on the bridge between Cincinnati, Ohio, and Covington, Ky., was held by the Supreme Court of the United States to be a regulation of interstate commerce, and therefore, beyond the scope of the legislative power of a state. The regulation of ferries, including those operating across bodies of water forming state boundaries, and between points in different states, had been regarded as the function of local authorities.

The right of the state to prohibit the entry into the state of intoxicating beverages was denied when the goods were imported into the states in the original packages as articles of interstate commerce. The law on this subject has been modified, and such shipments are now governed by act of Congress which prohibits their entry into states where the sale of intoxicating beverages is prohibited by state law.

The imposition of license fees on persons or employments, even though not discriminatory, has been held to be unlawful when the fees are, in effect, regulations of interstate commerce. Such regulations include taxes imposed upon persons soliciting orders for goods or freight to be shipped into or out of a state to or from another state.

Laws passed by the states in the exercise of their police powers are valid, although they may incidentally affect interstate commerce. The states may exclude persons or goods by quarantine; regulate or restrict the sale of merchandise by pure-food laws or other legislation in the interest of public health or morals; regulate the use of highways; impose taxes upon the use of the highways; place conditions on the conduct of business by foreign corporations within their limits; and oust corporations or associations which are engaged in activities deemed contrary to public welfare. In a few cases which involve direct regulations of interstate commerce, state laws have been held operative in the absence of federal regulations on the subject.

It is the «elementary and long-settled rule that there can be no divided authority over interstate commerce, and that regulations of Congress are supreme.» In cases where, from the particular nature of the subject, the state may exert authority until Congress acts, it is under the assumption that Congress by inaction has tacitly authorized the state to do so. Action by Congress, though not expressly inhibitive, destroys the possibility of such assumption, since such action covers the whole field and renders the State impotent.» (*Southern Railway Co.* v. *Reid,* [222 U. S. 424] 1912; and *Railway Co.* v. *Hardwicke Farmers' Elevator Co.,* [226 U. S. 426], 1913).

Problems and Regulation of Rapid Expansion.—The rapid extension of the railroads of the country in the decade following the Civil War resulted in a complete change in the aspect of American commercial problems. Not interstate commerce, but the most important instrumentality thereof, appeared to be in urgent need of regulation. The authority given by the act of Congress of 15 June 1866 had facilitated railroad connections and the establishment of continuous lines, extending beyond the boundaries of states, thereby making their control more difficult. The railroads thus connected were gradually consolidated by merger, purchase or lease into larger interstate systems. Competition among these systems was reduced or eliminated by pooling agreements under which

railways shared traffic or earnings or both. New lines projected as competitors to existing ones were bought out, or frozen out by means of stock manipulation or legal and political warfare. Lines were built for the sole purpose of harassing other lines or forcing them to buy their new rivals. Of the many evils growing out of unregulated railroad operation, one of the greatest was the practice of discriminating in services and rates among individual shippers, commodities and localities. Favored shippers were enriched at the expense, and often by the ruin, of their unfavored rivals, who had to pay more for services or were denied equal services. The prosperity of industries, communities, and whole sections of the country with the farms, mines and industries they contained, were dependent upon the favorable treatment of those who commanded the means of transportation.

The Granger movement, which started after 1870, resulted in the enactment of stringent regulative laws in the states of the Northwest and Middle West. Local or state legislation was found to be of little avail. A large part of the railroad traffic was interstate and lay largely outside of state control. Much of the grain and other produce that went into the elevators and warehouses was intended for transshipment to other states, or for export to foreign countries. Terminal services could not be effectively regulated, nor could unfair and discriminative through rates be prevented by state regulation alone. The panic of 1873 halted railroad building temporarily, and the severe Granger laws were modified or found to be ineffectual to reach the real difficulty where only federal regulation could reach. Often the only limitation on charges was «what the traffic would bear.»

The first attempt at comprehensive federal transportation regulation by Congress was made in 1873, when a bill was introduced to forbid any railroad company to charge more per mile for a short haul than for a long. This crude measure, which took no account of the important economic principle of railroad operation, fortunately was defeated in Congress. Representative (former Judge) Reagan, of Texas, introduced into the House of Representatives in 1878 a series of bills providing for railroad regulation, some provisions of which ultimately found their way into the Cullom Bill. The Windom and Cullom reports to Congress recommended federal legislation in 1874 and in 1886, respectively. The act to regulate commerce was enacted 4 Feb. 1887. This act was based primarily upon the Cullom Bill. The principal objects of this law, as defined by the Supreme Court, were: «to secure just and reasonable charges for transportation; prohibit unjust discrimination in the rendition of like services under similar circumstances and conditions; to prevent undue preferences to persons, corporations, or localities; to inhibit greater compensation for shorter than for longer distances over the same lines; and to abolish combinations for the pooling of freights.» (*Interstate Commerce Commission* v. *Baltimore,* [145 U. S. 263], 1892). The act to regulate commerce originally was applicable only to carriers wholly by rail, or partly by rail and water, and to the instrumentalities of shipment and carriage via such carriers. Transportation on water routes, by navigation companies or individual owners, operating their lines or vessels independently and not under direction of a railroad as components of a combined rail and water route, was not in the purview of the law. The Hepburn Act of 29 June 1906, extended the act to petroleum pipelines and specified with great particularity the «services required in connection with the receipt, delivery and transfer in transit, ventilation, refrigeration, elevation, storage or handling of property transported.» The Mann-Elkins Act of 18 June 1910, made telegraphs, telephone (wire or wireless) and cables, also express companies, sleeping-car companies, bridges and ferries, subject to the act. Communication facilities, since the Federal Communications Act of 1934, are regulated by the Federal Communications Commission. The pooling of freight was absolutely prohibited by the act to regulate commerce. This provision has been modified by the Transportation Act of 1920, as will be discussed later.

Rates.—Efforts were made by the carriers to secure uniformity of rates by agreement among the member railroads in each of the several regional traffic associations. Such agreements, however, were declared by the Interstate Commerce Commission, which had been created to administer the law, and by the United States Supreme Court, to be in violation of the Sherman Antitrust Law, being «contracts in restraint of trade.» (*United States* v. *Trans-Missouri Freight Association,* [166 U. S. 290], 1897; and *United States* v. *Joint Traffic Association,* [177 U. S. 505], 1898).

Regulation was tending to supersede competition as a means of adjustment of rates and services. Nevertheless, mergers or combinations of parallel and competing lines and systems were prevented by state laws, which were held to be constitutional by the United States Supreme Court. This same court ordered the dissolution of the Northern Pacific and Great Northern merger, and dissolved the combination, through stock ownership, between the Union Pacific and Southern Pacific systems. (193 U. S. 197), 1904; and (226 U. S. 470), 1913. The prohibition in the original act of lower rates for a long haul than for a short haul was unconditional; but the commission, with the concurrence of the courts, applied the qualifying phrases attached to other provisions of the law so that, where a railroad between two given terminals is in competition with an all-water route, or a foreign overland route out of the jurisdiction of the commission, it was decided that there was «a substantial difference in the circumstances» such as would warrant the establishment of a lower through rate for the longer haul from terminal to terminal than for a shorter haul to intermediate points on the same line. (168 U. S. 144), 1897. The Mann-Elkins Act of 1910 amended the act by eliminating the phrase «under substantially similar circumstances and conditions.»

The rates established by the commission were made final except for review on constitutional grounds or questions of law—as being denials of the equal protection of the law or involving the taking of property without compensation, or other error of law or lack of jurisdiction. The requirement to construct and operate switch connections by request of any lateral or branch line or shipper, if practicable and justified by

the business furnished, and the «commodities clause,» which forbade railroads to haul coal from mines owned or controlled by them, were other features of the Hepburn Law of 1906. It was found necessary several times to increase the severity of the penalties provided by the original law for discriminations in rates and services. The Elkins Act of 4 Feb. 1903, made the giving of rebates, or the granting of any special favors which were differentials in effect, punishable by the imprisonment of the agents or officers responsible for the wrong and for those who received the rebates, as well as by the imposition of fines on the corporations. But the principle of selling cheaper at wholesale than at retail has been declared by the courts to be operative in the sale of transportation, just the same as in the sale of other services or of commodities. The existence of «large shippers under single control, sending continuous quantities at stated and regular intervals, also weight and bulk, convenience or inconvenience, may be considered in rate making.» (*Interstate Commerce Commission* v. *Chicago & Great Western Railroad Company,* [209 U. S. 108], 1908.

In 1939 the Interstate Commerce Commission permitted lower rates on trainload than on carload movements of the same commodities to be established by certain railroads. (235 ICC 487), 1939.

In determining the reasonableness of a charge, the interests of the carriers, the shippers, and the public must all be considered. The cost of service to the carrier is a factor in rate making, but impracticable as the sole basis of rate making because of lack of adequate cost data and variations in cost under different conditions of traffic. The value of the service to the shipper is another important factor. So, too, is the density of the goods and the volume of the traffic. The relative ability of the items of traffic to bear the charges must be considered. Rates may be unfair because unreasonably low, and other rates may be unfairly high, or relatively unfair compared with other rates, because unreasonable when compared to other rates. As a minimum the commission and courts tend to require that rates must be compensatory, covering and more than covering «out-of-pocket costs.»

In order that the Interstate Commerce Commission might have information respecting the value of railroad carriers' property, the act of 1 March 1913, directed the commission to make a physical valuation of all railroad property in the United States. It was assumed by many that the value so found would be less than the par value of the stock in the hands of shareholders, and that the infiltrations of «water» could be squeezed out of the nominal capitalization. The valuations found by the commission generally have not shown over-capitalization of the kind and extent anticipated.

Special Legislation.—The Panama Canal Act of 24 Aug. 1912 made it unlawful for any railroad to own, lease, operate, control or have any interest (by stock ownership directly, or indirectly through a holding company or individual stockholders) in any carrier by water or any vessel carrying freight or passengers operated through the Panama Canal or on any other water route with which it (the railroad) does or may compete. By this act also the Interstate Commerce Commission was authorized to require the establishment of physical connection between the lines of carriers by rail and the docks of carriers by water by means of spur tracks. The connection must be reasonably practicable, and the amount of business must justify the outlay, the commission to apportion the cost of installation and determine the conditions and charges of operation. The law applies even when the dock belongs to neither carrier, so that piers owned by municipalities or independent wharfingers are brought to this extent under federal regulation. The commission may determine through routes and maximum joint rates, establish maximum proportional rates by rail to and from ports, to and from which traffic is carried by water. Any carrier by rail entering into engagements with a carrier by water for handling through business may be required to enter into similar arrangements with any or all lines of steamships operating from the same port.

The Sherman Antitrust Law of 2 July 1890, though it purports to be an act «to protect trade and commerce against unlawful restraints and monopolies» was at first declared inapplicable to a monopoly in the production of a necessary of life, which is transported to, and sold in, every corner of the land. But the original sugar-trust decision has long since been overruled, and the prohibition of the Sherman law of trading in trust products makes it a most effective regulation of interstate commerce. The power of Congress to prohibit, as well as to regulate, trade is invoked also in the Federal Meat Inspection and the Food and Drug laws. Acts of Congress prohibiting interstate commerce in the products of child labor were declared unconstitutional by the United States Supreme Court, but subsequent legislation has been upheld as constitutional when drafted so as to be clearly applicable to interstate commerce.

The Interstate Commerce Commission has nothing to do with the administration of these laws. The regulation of transportation and rates of common carriers on water routes, which the government has assumed, is in the hands of the United States Maritime Commission. This commission does not have jurisdiction over the rates of contract carriers or over the port-to-port rates of inland water carriers, and only limited jurisdiction over carriers by water engaged in overseas trades.

Government Railroad Operation.—The regulatory powers of the Interstate Commerce Commission were, to some extent, superseded by the appointment, as a war measure, of the director general of railroads, and the establishment of the United States Railroad Administration, which administered the railroads from 1918 until 1920. During this period the government operated the railroads and certain other transportation facilities as government enterprises. The earnings of the corporations were guaranteed upon the basis of the earnings of the prewar period, and the properties were operated as integrated units as a war measure. Many competitive practices deemed wasteful were eliminated during this period of «government operation.» All objectives were subordinated to the military use of the railroads during the war emergency. The Interstate Commerce Commission continued to receive reports from the carriers, but many of its normal regulatory powers

were suspended, to be revived again after the war period.

Transportation Acts, 1920, 1933.—In 1920 the railroads were returned to their corporate owners by the Transportation Act of 28 Feb. 1920 (41 Stat. L. 458). This act not only provided for the return of the railroads to their corporate owners but amended in many particulars, the Interstate Commerce Act (the act to regulate commerce of 1887, and its amending acts). An experiment was made in establishing railroad rates and charges so that the carriers by groups would earn a fair return upon the property invested and used in public transportation service, with the proviso that railroads earning more than the fair return would be required to share half of the excess earnings over a fair return with the United States government. This statutory rule of rate making and recapture of excess earnings was held to be constitutional by the United States Supreme Court in *Dayton and Goose Creek R. R. Co.* v. *U.S.* (263 U.S. 456), 1924. The rule of rate making (Section 15A) of the Transportation Act declared constitutional in this case was amended by the Emergency Railroad Transportation Act, 1933 (48 Stat. L. 211). As now amended, the rule of rate making of the Interstate Commerce Act (Section 15A) now requires that in the exercise of its power to prescribe just and reasonable rates, the Interstate Commerce Commission shall give due consideration among other factors to: (1) the effect of the rates on the movement of traffic; (2) the need, in the public interest, of adequate and efficient railway transportation service at the lowest cost consistent with the furnishing of such service; and (3) the need of revenues sufficient to enable the carriers under honest, economical and efficient management, to provide such service. (48 Stat. L. 220.)

The Emergency Railroad Transportation Act, 1933, also provided for the establishment of the office of the federal co-ordinator of transportation to foster and protect interstate commerce in relation to railroad transportation by preventing and relieving obstructions and burdens resulting from the acute economic emergency, and to safeguard and maintain an adequate national system of transportation. This office was filled from 1933 to the termination of the office in 1936 by Hon. Joseph B. Eastman, then a member of the Interstate Commerce Commission, and now chairman of that body. The most comprehensive studies of transportation ever undertaken in the opinion of many transportation experts were made by the staff of the co-ordinator. Much of the data revealed by these studies has been of inestimable value in improving and developing transportation in the United States.

Interstate Commerce Act.—As a result of the passage by Congress of the Motor Carrier Act, 1935 (49 Stat. L. 543), the Interstate Commerce Commission now has jurisdiction over motor carriers engaged in interstate commerce. The Motor Carrier Act of 1935 is now Part II of the Interstate Commerce Act. In the interests of clarity it might be pointed out that the Interstate Commerce Act, Part I, consists of the original act to regulate commerce of 1887, sometimes known as the Cullom Act (24 Stat. L. 379) as amended, supplemented and implemented by the following acts:

Amendments—2 March 1889 (25 Stat. L. 855)
Amendments—10 Feb. 1891 (26 Stat. L. 743)
Joint Ticket Act—8 Feb. 1895 (28 Stat. L. 643)
Hepburn Act and Cormack Amendment—29 June 1906 (34 Stat. L. 584)
Destruction of Records Act—25 Feb. 1909 (35 Stat. L. 648)
Mann-Elkins Act—18 June 1910 (36 Stat. L. 539)
Panama Canal Act—24 Aug. 1912 (37 Stat. L. 566)
Valuation Act—1 March 1913 (37 Stat. L. 701)
First Cummins Amendment—4 March 1915 (38 Stat. L. 1196)
Federal Possession and Central Act—29 Aug. 1916 (39 Stat. L. 645)
Esch Car Service Act—29 May 1917 (40 Stat. L. 101)
Commission Reorganization Act—9 Aug. 1917 (40 Stat. L. 270)
Priority Act—10 Aug. 1917 (40 Stat. L. 272)
Federal Control Act—21 March 1918 (40 Stat. L. 451)
Transportation Act—28 Feb. 1920 (41 Stat. L. 456)
Amendment of Valuation Act—7 June 1922 (42 Stat. L. 624)
Ticket Sales Act—18 Aug. 1922 (42 Stat. L. 827)
Limitation of Overcharge Claims Act—7 June 1924 (43 Stat. L. 633)
Transportation of Blind—26 Feb. 1927 (44 Stat. L. 1247)
Newton Act—4 March 1927 (44 Stat. L. 1446)
Notice and Filing of Claims—23 April 1930 (46 Stat. L. 251)
Amendments—28 Feb. 1933 (47 Stat. L. 1368)
Emergency Railroad Transportation Act—16 June 1933 (48 Stat. L. 1933)
Amendments—27 June 1934 (48 Stat. L. 1264)
Amendments—23 May 1935 (49 Stat. L. 287)
Amendments—16 July 1935 (49 Stat. L. 481)
Amendments—9 Aug. 1935 (49 Stat. L. 543)
Amendments—12 Aug. 1935 (49 Stat. L. 607)

To these should be added the Elkins Act (32 Stat. L. 847), 1903; the Expediting Act (32 Stat. L. 823), 11 Feb. 1903; Compulsory Testimony Act (27 Stat. L. 443) 11 Feb. 1893; Immunity of Witnesses Act, (34 Stat. L. 798) 30 June 1906, etc.

Part II of the Interstate Commerce Act consists of the Motor Carrier Act (49 Stat. L. 543), 9 Aug. 1935 and the act of 29 June 1938.

Scope of Present Regulation.—The present scope of federal regulation of interstate commerce conducted by carriers subject to the Interstate Commerce Act may be summarized by stating that the regulation includes jurisdiction over reasonableness of rates, unjust discrimination, undue preference or prejudice, publication of rates and charges, the supervision of pooling of traffic of the carriers by the Interstate Commerce Commission, regulation of accounts and statistics, suspension of unlawful rates, valuation of carriers, maximum and minimum rates and charges, extension and abandonment of railroad facilities, acquisition of control of carriers, consolidation or merger of carriers, regulation of carriers' finances, joint use of terminal and other facilities, labor disputes, and many other phases of the services and charges of interstate carriers.

The services and charges of interstate water common carriers with certain limitations upon

powers to regulate foreign and inland water carriers are now exercised by the United States Maritime Commission.

The services and charges of common carriers engaged in interstate air transportation and certain aspects of other air navigations are now regulated by the Civil Aeronautics Board of the United States Department of Commerce. Congress has enacted three major and several minor amending acts in the regulation of interstate air transportation: the Air Commerce Act, 1926; (44 Stat. L. 568); the Civil Aeronautics Act, 1938; (52 Stat. L. 980); U. S. Resolutions, Plans Nos. 3 and 4 (1940).

The regulation of communications—telephone, telegraph, cables, and radio—was placed under the jurisdiction of the Federal Communications Commission in 1934 by the Communications Act of that year (50 Stat. L. 197), 1934.

There is much sentiment for the more comprehensive and better integrated regulation of all phases of transportation—railroad, railway express, water, motor and highway, air and pipeline. The Transportation Bill of 1940 (76th Congress 3d. Session) provides for the comprehensive amendment and extension of the Interstate Commerce Act and other federal regulatory acts. See also ANTITRUST LAWS; COMMERCE, INTERNAL, OF THE UNITED STATES; UNITED STATES—*Industrial and Commercial Development* (Section 54); *Railroad Transportation* (Section 52); WATERWAYS OF THE UNITED STATES.

G. LLOYD WILSON,
Professor of Transportation and Public Utilities, University of Pennsylvania.

COMMERCE OF THE WORLD, International. The commerce or trade of the world consists of the exchange of the products of the nations of the world, including their dominions, colonies, and possessions, with each other. It includes not only the exchange of raw materials, semimanufactures, and finished products, but also the payments for services and the exchange of funds.

Economically, it is advantageous for nations to produce the goods or services in which they are relatively more efficient than other nations, and to exchange these products or services for those produced by other nations in which the latter, in turn, are relatively more efficient. All phases of commerce, local and intranational as well as international, are parts of the world-wide efforts of men to gain a living and to improve the quantity and quality of the goods and services consumed by individually and collectively producing goods and services to use and to exchange for others. It is a kind of international division of labor from which, as Adam Smith observed, so many advantages are derived. He stated his conviction that the division of labor arises from a propensity in human nature to exchange or barter one thing for another, a trait which is found in man alone. ('Wealth of Nations,' chapter 2.)

Perhaps if there were no nations or other political or governmental subdivisions of the world, those who lived in one part of the world would produce goods or services of destructive kinds and exchange them with the natives of other parts of the world for their products, because geographic influences tend to make the production of certain types of goods possible or easier in certain parts of the world than in others. National resources, such as coal, oil, and forest products, are found in certain areas and not in others. As men became aware of the products of different areas and the usefulness of these goods, they were eager to obtain them and to exchange their native products for them. The travel of men into other parts of the world made them aware of other goods and other services, and incited a demand for them. Governments and international relations tend to enhance the ease with which products of different parts of the world are exchanged, unless artificial trade barriers are erected by nations against the goods of others or trade in these goods.

Natural World Divisions.—The world must be divided into three great natural divisions. One is the broad tropical belt stretching around the globe at the equator. On either side of this area are temperate zones. Between the 30th parallel of north latitude, which runs approximately through New Orleans, Cairo, and Shanghai, and the 30th parallel of south latitude, which runs through southern Brazil, the southern tip of Africa and the southern part of Australia, the products are chiefly tropical. North and south of these lines the products are chiefly those of temperate climates. The area between these two lines, the 30th degree north and the 30th south, is about one-half of the land surface of the globe, exclusive of the Arctic and Antarctic regions. This tropical area has about one-half of the world's population. Its products—cotton, silk, hemp, sisal, jute, rubber, hides, sugar, tea, coffee, cacao, and fruits—are demanded by the people of the temperate zone for food and clothing and for use in manufacturing.

The temperate zones, with one-half of the world's area and population, produce the cereals, meats and other foodstuffs, and here are located the great manufacturing sections of the world. These products of the temperate zones are demanded by the people of the tropics, for food, clothing, and the requirements of their domestic and industrial life. The interchange of the natural and artificial products of these two great climatic sections of the globe, the temperate zones and the tropics, is of advantage to those who live in all parts of the world. In addition to these climatic divisions of the earth's surface, it is also subdivided by the creation of continents and islands, separated by oceans across which the various products of these climatic divisions must be transported by vessels.

Certain of these natural sections were populated and their producing powers were developed long before others were developed. Western and southern Europe, northern Africa, India, China and the Euphrates valley, were the seats of a busy population long before America, central and southern Africa, Australia, or the islands of Oceania began to contribute their products to the commerce of the world.

It is the interchange of goods and services between these sections of the world and the various countries into which they are subdivided which constitutes international commerce.

Beginnings of International Trade.—The exchange began on a modest scale. Commercial caravans passed between Egypt and the Orient in the dawn of history. Coasting vessels plied between the cities of southern and western Europe long before America was discovered. These exchanges represented small parts of the

goods produced by the various countries of the world. It was not until the introduction of the compass, when men learned that the oceans were highways and not barriers to commerce, that trade between the great natural divisions and subdivisions really began.

It is not surprising, then, to find that the international trade of the world in 1700 was but about $350,000,000, of which about $200,000,000 was conducted by Europe and the remainder by Asia and America. Great Britain was then, as the British Empire now is, the leader in international commerce, her trade amounting in 1700 to about $50,000,000 a year; that of Spain, $40,000,000; France and the area embraced in prewar Germany, about $25,000,000; Spanish America and the East Indies, $40,000,000 each; and the British colonies, $10,000,000 at the beginning of the 18th century. By 1750 world commerce had doubled, amounting to about $750,000,000, and by 1800 it had again doubled, reaching $1,500,000,000 at that date. These figures are a rough aggregate of the imports and exports of all the countries of the world at that time, based upon statistical data available.

Causes of Expansion.—In the next half century, however, a series of events changed entirely the commercial movements of the world and greatly stimulated commerce, multiplying the interchanges and furthering development and the producing powers of the hitherto undeveloped regions of the globe. In 1819 a little vessel of 300 tons, the *Savannah,* crossed the ocean from the United States to Great Britain under steam power. The application of steam to ocean shipping decreased the time and also reduced greatly the cost of interchange between the great natural divisions of the world separated by the oceans. About the same time, the transportation of merchandise and people on land was undertaken by the use of steam power—the railway. The result of these two great contributions to transportation and commerce was that in the year 1850 there were upon the oceans nearly a million tons of steam vessels, and on land, 25,000 miles of railways; international commerce in that year was about $4,000,000,000, or nearly three times as much as in 1800. These inventions and their development revolutionized transportation and international trade as greatly as the application of steam power revolutionized the manufacturing industry in the industrial revolution.

From that time, international trade grew by leaps and bounds. By 1870 it was $10,000,000,000, and 1900, $20,000,000,000. Even this rapid increase, however, was outdone in the opening years of the present century, for in 1913, the year before the opening of the World War of 1914–18, the international trade of the world was $40,000,000,000. By 1925 it had reached $65,000,000,000, and by 1929 it had reached nearly $69,000,000,000.

The causes of this rapid growth following the application of steam to transportation were the opening of new areas to population and production; the reduction in the cost of transportation by which many articles were added to the list of international exchanges; the increased facility of intercommunication by the mails, the telegraph, the cable, the telephone and the wireless telegraphy; the increase of money and of banking power; and the development of great manufacturing systems, which supplied their products to all the world and took in exchange the manufacturing material from all sections of the globe. Steam vessels on the ocean grew from 1,000,000 tons in 1850 to 62,380,376 in 1925, and to 66,870,000 tons in 1938. Railway mileage increased from 25,000 miles in 1850 to 600,000 miles in 1938, of which 237,000 miles are in the United States. Ocean cables had increased to about 2,400,000 miles in 1938. Telegraph, telephone and wireless communication facilities connect all commercial centers of the world.

Meantime, world population increased with extreme rapidity, the result of the opening of new areas to population and production; and with the transportation of plentiful food supplies from the new areas, world population, which was but little more than 1,000,000,000 in 1850, grew to 1,829,807,000 in 1921, and to 2,115,800,000 in 1937, and the producing and purchasing power of each man greatly increased. North America, which had in 1800 but about 7,000,000 people, had in 1920 about 140,000,000, and in many other areas the development of population and producing power was phenomenal.

The increase of transportation was accompanied by reduction in the cost of moving merchandise between the continents and climatic sections. Wheat, corn, meats, cotton, and other manufacturing materials of North America were transported to Europe, and the manufactures of that continent sent in exchange; the meats, wool, hides, and grain of South America and Australia crossed the equator to Europe, and were also paid for in manufactures; and the tea, coffee, cacao, spices, sugar, fruits, and manufacturing materials of the tropics were sent to the north temperate zone in greater quantities, and were paid for in the products of the farms and factories of the temperate zones, upon which the tropics rely for their flour and meat, as well as clothing and other manufactured articles, or in services such as shipping.

Formation of Trade Records.—Records of world international trade are formed by aggregating the imports and exports of all countries of the world, and while we can only determine the value of the trade of any given country by aggregating its imports and exports, it must be remembered that the aggregation of the imports and exports of all the countries of the world necessarily counts the merchandise twice: once when it leaves the country of production as an export, and again when it enters some other country as an import. In other words, when it is said that the international commerce of the world in 1929 was over $68,000,000,000, it means that the value of the merchandise forming that trade was about one-half of that sum, or about $34,000,000,000, since its value was counted twice, once as it left the country of production as an export, and again when it entered the country of its destination as an import. The total international commerce in 1938 was nearly $28,000,000,000, or, eliminating duplications, about $14,000,000,000.

The intercontinental trade of the world is much less than is usually supposed. Much of the trade of the various countries occurs with adjacent or neighboring countries on the same continent. The trade of the United States with Canada, for example, which now amounts to over a billion dollars a year, is properly con-

sidered international commerce, yet none of it leaves the continent, and the United States trade with all of the North American countries in 1937 was over $5,000,000,000. Thus about one-fourth of the international trade of the North American countries in 1937 was intracontinental, or trade within the continent, while about three-fourths was intercontinental, or trade with other continents.

World trade increased materially until 1929. The aggregate value of the foreign trade (exports plus imports) of the world was about $68,600,000,000. The increase was due, in part, to a real increase in the volume of trade, and partly to price advances, world trade prices.

Balance of Trade.—Theoretically, world imports should equal world exports. Owing, however, to the stricter control of imports, to differences in methods of valuation, and because most countries include ocean transportation in the value of their imports, world imports always exceed world exports when totaled. The United States, Canada, Mexico, Cuba, some of the Central American countries, the Philippines, and the Union of South Africa value their imports f.o.b. the foreign country from which they are received, whereas in all other countries imports are valued c.i.f. (cost, insurance, and freight). The value of imports and exports of 109 countries in 1937, according to the figures of the United States Department of Commerce, exceeded $31,000,000,000, the imports exceeding $16,000,000,000, and the exports a little less than $15,000,000,000.

The excess of imports by the European countries is attributable to the fact that they are compelled to draw upon other parts of the world for a large proportion of their food and manufacturing material, and as they have little except manufactures to offer in exchange, their imports exceed their exports, the difference being made up by the earnings of their steamships and capital.

Recent Trade Figures.—In 1929, the value of world trade, arrived at by adding together the figures of the recorded external trade after converting the figures of the various statistical areas of the world into a common monetary unit, in this case into United States gold dollars (old parity of 23.22 grams to the dollar), amounted to $68,619,000,000, of which $35,595,000,000 represented imports, and $33,024,000,000 represented exports.

Since 1929 world trade has declined because of world-wide economic depression and political unrest and wars which have swept the world.

The figures compiled by the Economic Intelligence Service of the League of Nations indicate that world trade fell sharply after 1929, then recovered in the years following 1934, and fell again in 1938. The value of world trade in recent years and the percentage relationship of the world trade for years following 1929 compared with the value of world trade of that year are as follows:

Year	Value of World Trade in U. S. Gold Dollars (000,000 omitted)			Percentage Movement 1929 Base	
	Total	Imports	Exports	Imports	Exports
1929	$68,619	$35,595	$33,024	100%	100%
1932	26,853	13,968	12,885	39.2%	39.0%
1934	23,314	11,981	11,333	33.7%	34.3%
1936	25,723	13,142	12,581	36.9%	38.1%
1937	31,769	16,342	15,427	45.9%	46.7%
1938	27,736	14,319	13,417	40.1%	40.6%

The international trade statistical data compiled for 109 countries of the world by the United States Department of Commerce, Bureau of Foreign and Domestic Commerce, for selected years since 1911, to and including 1937, are shown in the accompanying table.

INTERNATIONAL TRADE—IMPORTS AND EXPORTS—IN GOLD DOLLARS

Year (109 Countries)	(000,000 omitted) Imports	Exports
Average 1911–1913	20,485	18,961
1913	21,614	20,102
Average 1926–1930	33,011	30,566
1932	13,931	12,614
1933	12,431	11,412
1934	11,938	11,050
1935	12,192	11,322
1936	13,035	12,281
1937	16,167	14,932

Trade and War.—The years 1938 to 1940 have been marred by serious political, economic, and military troubles in Europe and Asia. This period has been characterized by economic and governmental insecurity and unrest. It has been attended by unprecedented armament races; by industrial depression; by disastrous fall of prices of some important agricultural products; by decline in the exchange value of many currencies; by the increased regimentation and control of foreign trade, as well as domestic commerce by totalitarian governments; by the absorption of economic domination and by military conquest of many nations, until comparisons of world trade for these years become almost impossible and meaningless. The growth of barter between countries in which price comparisons are of little significance tends to blur the comparisons further.

The United States is the only major commercial nation that is making efforts to lower trade barriers and to promote world trade through its trade-agreements program. The other nations of the world are moving in the reverse direction and are tending to limit or destroy world trade by the development of economic self-sufficiency, high foreign-trade tax programs, foreign-trade quotas, exchange restrictions, prohibition of certain phases of foreign trade, currency manipulation, etc.

Owing to restriction of foreign trade and to lower prices, the foreign trade of the world declined to $27,071,600,000 in 1938 as compared with $31,153,100,000 in 1937, a decline of 13 per cent.

The foreign trade of the United States fell in 1938 to $2,985,526,000 as compared with $3,799,386,000 in 1937, a decline of 21.4 per cent. Exports from the United States declined 7.6 per cent, but imports were reduced 36.4 per cent.

With the outbreak of the European war in September, 1939, world trade, already adversely affected by the Japanese-Chinese hostilities in Asia, and by the Spanish War and other wars in Europe and Africa, has been further adversely affected by the wholesale destruction of shipping, by import and export restrictions, and by economic blockade. See also BALANCE OF TRADE; IMPORTS AND EXPORTS; UNITED STATES—*Foreign Commerce* (Section 53).

Professor of Transportation and Public Utilities, University of Pennsylvania.

COMMERCIAL ASSOCIATIONS.

Early Organizations.— There were but few commercial associations in the United States before the Civil War. As a rule, only the larger cities possessed them. The functions of these organizations were scarcely more than to hold annual meetings to elect officers and to have occasional banquets where local politicians spoke. The strictly commercial organizations frequently aimed to maintain a produce exchange and provide room-trading facilities in such staples as grain, cotton and tobacco. The larger of these associations compiled and published trade statistics in their annual reports. These early statistics are very interesting to the historian. The volumes of the New York Chamber of Commerce give statistics of the movement of freight by the Erie Canal. The Cincinnati reports chronicle the rise and fall of the Ohio River trade and give the figures for Western pork packing. The Saint Louis volumes contain an account of the lumber rafts of the Mississippi River, of the Galena lead trade, of the furs and gold brought down from the upper waters of the Missouri River, of the buffalo skins shipped East from the plains and of the merchandise which passed to the Southwest by wagon over the Santa Fé trail.

Trade Associations.— After the Civil War there began to be formed in various parts of the country organizations of men engaged in the same line of trade. The wagon makers united; the window glass blowers got together; the hotel keepers began to consider their problems, etc. These various organizations, planned along trade lines, were local, state or national in scope. Among the important functions which they attempted were to standardize commercial usages, to exchange craft knowledge between the members and to control prices more or less directly. Some of these associations have done good work. The Society for Testing Materials (an organization of purchasing agents) has formulated many scientifically complete buyers' specifications. The Association of Railway Master Mechanics called attention, some years ago, to the dearth of skilled mechanics, and started the movement for apprenticeship courses and shop schools, which has accomplished so much in the hands of American railroads. Some of the trade associations have brought their members upon a more or less uniform plane of efficiency by prescribing a standard system of cost accounting suited to the industry. The majority of the associations formed along trade lines are of merchants. If an organization be of wholesalers it is very likely to plan trade-getting trips, to make special arrangements for buyers' weeks either by securing railway transportation of members at reduced rates or by giving free transportation to those who buy a specified amount of merchandise, and to organize a credit rating bureau. Organizations of retailers often make arrangement for style shows, draw up rules to prevent unprofitable advertising, operate a co-operative delivery system or establish a local credit bureau to identify delinquent debtors.

The Civic Basis of the Modern Movement.— The recent rapid growth of commercial associations in this country may be attributed to a revival of local civic life and to a new understanding of the basis of local business prosperity. The civic motive is about equal in importance with the economic one in the typical modern board of trade or chamber of commerce. There is coming to exist a more vivid civic consciousness. People now travel about so much that they get into the habit of appraising towns and cities as communities and of comparing them with their home town. Young businesses now look about more diligently for an advantageous location than was once the case, and less frequently grow up where the original idea happened to strike the founder. In other words, there is now a competition not only of individuals and firms but of neighborhoods for social, civic and economic prestige.

So long as the primitive communities had mud roads, oil lamps at the street corners, individual wells in the back yards; so long as locomotion was on foot or on horseback and there was plenty of space between the structures, the administration of local government was a routine affair. But when it became necessary to provide waterworks, grant franchises to a variety of public utility corporations, undertake such matters as street paving and the cleaning and sprinkling of streets, erect expensive bridges, maintain an efficient fire department, administer a complicated building ordinance, provide parks and technical schools and consider comprehensive schemes of city planning, it began to be realized by business men that the administration of a city was very much like that of a large business. And so there came a demand for "a business administration."

In relation to this demand commercial associations have proved to be a convenient means for free and informal discussion. They have provided a centre where the progressive elements of the community could gather. They may be called the "planning department" of the city government, to borrow a term from 'Scientific Management.' They are training schools for a new type of citizenship. This function has been defined by Pres. H. A. Garfield of Williams College, in an address before the Cleveland Chamber of Commerce as follows: "If I may so express it, the centre of political gravity is gradually settling, and if it passes from our legislative bodies to the electorate there must be found a workable way of securing deliberation among the voters. If it should come about that the only place for free and effective deliberation is among the voters prior to election day, then, plainly, bodies like the Cleveland Chamber of Commerce will become normal centres for the consideration of public questions, and their influence will become increasingly important."

The Economic Basis.— Membership committees of commercial associations have often to deal with the man who says, "How can I feel it in my business?" "What is there in it for me?" This brings up a critical economic point, the answer to which is, in brief, that business has been rapidly changing in character, and changing in such a way as to produce a more intimate local solidarity in economic matters. Business units have grown larger, margins of profit have grown smaller, more care is needed in buying, delays in local traffic are more hurtful, competition for labor is ad-

vancing to a higher plane, a wider and more even market is demanded, more science is available and more is needed. Of the local solidarity of business let us select one phase only,—namely, that which pertains to the equipment of a place as a market. How does a city become a good buying and selling centre? Merchandising involves measurement of quantities (systems of weights and measures), measurement of qualities (systems of grades), means of protecting merchandise while it is being held (warehouses and warehousing law) and an adequate assortment for the buyer. A sufficient assortment can only be ensured for out-of-town trade buyers by a systematic survey of the merchandise requirements of the tributary territory. A market also requires fair prices. The formula for fair prices is to bring to bear upon each transaction all possible elements of supply and demand. This means to bring past and future supply and demand to bear upon the present by providing adequate warehousing and cold storage. It means to bring to bear upon the market of one commodity the state of the market for other commodities which are either its raw materials or its manufactured derivatives; a thing which can be done by having the converting or manufacturing interests actively represented. It involves bringing the price of money to bear upon the price of goods by taking such steps as will interest the banks actively in commercial transactions and will make out of goods in storage an acceptable collateral for loans. It means, also, to bring different markets to bear promptly upon each other, by adequate market reports. A perfect market must have flexible credit for persons of ability and character. It must have efficient local trucking. It requires prompt railway transportation, which means not only the presence of railways but proper rates, frequent train service, a minimum of delay, convenient package car accommodations and a low percentage of loss and damage. A market is completed by an adequate information service of trade and general papers, and by a wide range of service industries to facilitate each item of trading transactions. From this bare enumeration it can be seen that a market is a complex thing. A large market is, indeed, about the most complex thing the mind of man has devised. Markets, well organized and of high efficiency, are still rare in the United States. Such a market does not merely happen; it does not grow like Topsy, nor emerge Phœnix-like from the fires of competitive hatred, nor blossom from the narrow stem of policy known as "every man minding his own business." It is the result of persevering joint effort. The economic activities of commercial associations can be scarcely more than suggested by means of a few illustrations. The Commercial Association of Bridgeport (Conn.) maintains a trade school. At Grand Rapids vocational guidance for boys over 15 years of age is provided. The Lynchburg (Va.) Chamber of Commerce promoted a new hotel, and finally a municipal public market. Atlanta (Ga.) manages a buyer's convention twice a year. The New Orleans Merchants' and Manufacturers' Bureau publishes a Spanish magazine, *Mercurio,* twice a month; the Saint Louis Manufacturers' and Exporters' Association also published a monthly journal in Spanish. The Galveston (Tex.) Commercial Association sent a party of merchants to Guatemala, Honduras, Costa Rica and Panama in 1913. The San Francisco Chamber of Commerce helped to found the Remedial Loan Association. The Spokane Chamber of Commerce has aided the North Pacific Fruit Distributors to organize. The Minneapolis Civic and Commercial Association took a census of farmers' opinions on good roads. The Houston (Tex.) Chamber of Commerce maintains a bureau which chronicles all freight delays in and out of the city. Hannibal (Mo.) has a Commercial Club which bought a large tract of land between the tracks of three railways and sold it to new plants. A number of associations, including those of Davenport, Iowa, Williamsport, Pa., Rockford, Ill., Jackson, Mich., and Boston, Mass., have loaned credit to new business concerns. It is now estimated that there are over 3,000 paid secretaries of commercial associations in this country. In 1912, President Taft, through Secretary Nagel of the Department of Commerce and Labor, invited the commercial organizations of the country to attend a national conference. The result was the formation of the Chamber of Commerce of the United States. This organization serves as a means of formulating the opinion of the business men of the country upon such economic questions as require a certain national co-ordination in action, or which rise into the domain of practical politics and require legislation or the attention of the administrative departments of government. The organon of this Chamber is *The Nation's Business.* See CHAMBERS OF COMMERCE.

COMMERCIAL COLLEGES. See EDUCATION, COMMERCIAL.

COMMERCIAL COURTS. Tribunals distinct from the ordinary civil courts, in some countries are established in various commercial towns, or within certain districts, to settle disputes with regard to rights and obli-

gations between persons engaged in trade, with the assistance of experienced merchants, by a brief process, according to equitable principles. The general introduction of tribunals of this sort began in the Middle Ages. The first was probably that established at Pisa, in the 11th century, and the basis of its decisions was the code of maritime laws of Pisa, confirmed by Pope Gregory VII in 1075. At first the commercial tribunals were not so much courts established by government as arbiters of disputes, freely chosen by the merchants and confirmed by the governments. Under the name of commercial consuls such committees of arbitration were appointed in all the great commercial cities of Europe; and in the course of time they really became tribunals of justice, and were, in part at least, administered by men of legal learning and experience. Pope Paul III confirmed the commercial consuls in Rome. Francis II in 1560 granted to the Parisian merchants particular arbiters for the adjustment of commercial disputes; and in 1563 was established the Parisian Court of Commerce, consisting of a judge and four consuls. The same thing soon followed in all the important commercial towns of France. In London Henry VII appointed particular commercial judges. The president of the commercial tribunal for the Hanse towns, established in 1447, bore the name of alderman. At Nuremberg, in 1621, a similar tribunal was instituted under the name of inspectors of the markets. The diets of the empire even called upon the German princes and commercial cities to follow this example, as the decrees of the empire in 1654 and 1668, and the decree of the Imperial Commission of 10 Oct. 1663, show. In many of these cities, as in Frankfort-on-the-Main, and in Leipzig, they were not so much independent authorities as delegates from the city councils. When commercial courts take cognizance particularly or solely of disputes relating to maritime affairs, they may be called courts of admiralty. Such a court was erected in Hamburg in 1623. The internal regulations of commercial courts commonly require that a part of the members, or at least the presidents, should be lawyers; the rest are for the most part experienced merchants, who are better adapted than regular judges to give counsel on commercial affairs, with which they are more acquainted, and which very often are not to be reduced to simple principles of law, but are to be decided according to commercial practice. Their jurisdiction commonly extends over all commercial disputes, matters of exchange, insurance, freight, bottomry, average, etc.; and further, over bankrupts, the hiring of shops and stores, clerks and apprentices; the debts of those who receive goods from merchants upon credit; and all natives and foreigners who traffic in the place and are found there, all shipowners, contractors for transporting goods, brokers, factors, etc., are obliged to submit to their decisions. They do as much as possible by oral investigation; and the intention of their institution is that they shall avoid the long and formal process of other courts. But when the difficulty and confusion of the matters in dispute occasion the necessity of an investigation in writing recourse is had thereto. The greater dispatch of these courts consists principally in this — that the defendant is orally summoned, once or several times, to appear before them at an early day, and if he fails to come, he can be brought by force. The complaint is then made orally, both parties are heard and sentence is given, if possible, immediately after. But as this can seldom be done, and most cases require reference to written documents, a day not far distant is appointed for the answer to the complaint and for the evidence on both sides, and the time is seldom or never prolonged. The remedies against a sentence must be sought from the same judges and are not easily obtained. Appeals are only allowed in very important cases, and upon the deposit of a large sum as a pledge that the final decision shall be obeyed without delay. The principal features of this process form the basis of most commercial codes. From the sentence of these tribunals appeal is made to the court of appeal within whose jurisdiction they happen to be. The other countries where these tribunals exist are Belgium, Spain, Portugal and Italy. See COMMERCIAL LAW; UNITED STATES COMMERCE COURT.

COMMERCIAL FERTILIZER. See AGRICULTURAL CHEMISTRY; FERTILIZERS.

COMMERCIAL GEOGRAPHY. Commercial geography is the study of the exchanges of merchandise between the geographic sections of the world. Nature has greatly diversified the productions of the globe. Tropical growths for example differ in quality from those of the temperate zones and those of the mountain regions differ from those of the plains. Certain areas are especially fitted to produce foodstuffs, others manufacturing materials and in still others, the circumstances of population, transportation and supplies of raw material and fuel have developed great manufacturing industries. Commercial geography studies these conditions and notes the production of each area, and the interchanges present and possible. It is in fact a study of the geography of commerce.

The great improvement in facilities of transportation, communication and production which have characterized recent years, has stimulated the study of commercial geography. World international commerce has made its chief growth in the life time of the present generation. It was but $4,000,000,000 in 1850, $10,000,000,000 in 1870, $20,000,000,000 in 1900 and then jumped to $40,000,000,000 in 1913, the year preceding the great European War, which disarranged the commerce of the entire world and especially that of the great European countries, the world's largest importers and exporters. International trade quintupled in the half century, 1850 to 1900, and then doubled again in the 13 years 1900–13. By 1929 it had increased to $68,000,000,000, though a considerable portion of this latter increase was attributable to an increase in prices rather than to an increase in volume.

This growth in international trade is, of course, very unevenly divided among the various countries and geographical sections of the world. The United States for example doubled its sales to Europe from 1900 to 1915, and doubled its purchases from that continent from 1900 to 1914, and this is true in a general

way of its trade with Asia, Africa and South America. Equally striking is the fact that the United States' imports of tropical and sub-tropical products, including those from island possessions, grew from $335,000,000 in 1900 to $1,060,000,000 in 1916, having thus actually trebled in value in the short 16-year period, and this is a mere illustration of the growing demand of the temperate zones upon the tropical world. The international trade of the United States averaged $15 per capita in 1850, $43 in 1913 and $78 in 1929. The international trade of all the countries forming the continent of Europe averaged $10 per capita in 1850, and $68 in 1929; that of the countries of the North American continent averaged $11 per capita in 1850, and $82 in 1929; that of the countries forming the continent of Asia 69 cents per capita in 1850, and $9.97 per capita in 1929. The contrast in commercial conditions in the different countries is illustrated by the fact that the commerce of China in 1929 averaged $3.30 per capita of its population, and that of Japan, which lies just alongside, $31.60 per capita in the same year. Commercial geography studies these currents and cross-currents of trade, and seeks to determine the underlying causes of the contrasts and changes which these studies disclose.

Nature divided the land area of the globe into two great land masses stretching from the Arctic regions of the north to the Antarctic at the south. Then she "cross-sectioned" these by climatic belts, thus multiplying the exchangeable qualities of the products of their respective areas. America stretches in a continuous land mass from above the Arctic circle at the north to within a comparatively short distance of the Antarctic circle at the south. The continent of Eurasia, which we improperly divide into Europe and Asia, stretches in a continuous land mass from above the Arctic circle well into the tropics, and then by one southern extension, Africa, extends well into the south temperate zone, while its eastern limb, the Malayan Peninsula, with the co-operation of the chain of islands extending to Australia, stretches well into the south temperate zone. These two great masses, America on the one hand and Eurasia with its southern extensions on the other, are separated by two great oceans, the Atlantic and Pacific, thousands of miles in width, while climatic conditions cross-section each into a half dozen distinct belts, Arctic and Antarctic, north temperate and south temperate, tropical and sub-tropical.

Local conditions within the continents also affect production and producing possibilities. The great elevations which we call mountains and the tablelands adjacent to them lift their producing surfaces into temperatures radically different from those lying alongside on a lower level. Certain areas in tropical America for example, which lie a mile or two miles above the ocean level, enjoy a temperate zone climate although distinctly within the area designated as the tropics, while the adjacent areas lying but a few feet above the ocean level swelter in the fiercest tropical heat and their respective products vary in like proportion. On the other hand, certain land masses in the far interior of the continents are so distant from the ocean that they receive little if any rain, for, as is well known, all the water which the land receives is carried to it by the currents of air which have obtained their moisture from the evaporation of the ocean. Air which has been so charged in passing over the ocean begins to lose its moisture in the form of mists, rain or snow as it passes over the land and is forced upward, and so may lose practically all of its moisture before reaching the far interior of the continent, especially if it crosses high mountain ranges in its passage. As a result, we have the great desert areas in central and southwest Asia, North Africa, in the western part of the United States, the interior of Australia and certain sections of South America. Thus certain areas which lie within the tropics may have a temperate zone climate and certain other countries in the temperate zone or tropics may be absolutely unproductive by lack of moisture, which is plentiful in the same latitude a few hundred miles away.

Air currents and the currents of water which they have formed in the ocean have also a marked influence upon the productive conditions of the land, especially in the vicinity of the ocean. The "trade winds" so-called or air currents moving from the north and south toward the equator to fill the partial vacuum caused by the upward movement of the intensely heated air of that region blow more and more toward the west as they approach the equator, by reason of the fact that the surface of the earth at that point is traveling toward the east more rapidly than that part over which they passed in their movement from the north or south. This continuous flow of air toward the west during untold ages has set up currents of water in the ocean over which it passes, which also move toward the west in the vicinity of the equator, and when these currents of water come in contact with the land of the continent, they are forced to the north or south as circumstances may dictate, and carrying the great masses of water heated by their long passage through the tropics affect, to a greater or less degree, the climate of the land masses with which they come in contact. The great northern equatorial current which flows west across the Pacific Ocean from the Panama Canal to the Philippine Islands and the Asiatic coast is deflected northward along the eastern frontage of Asia and thence eastward to the northwest coast of North America, carrying some of the heat which it received in the tropics and materially modifying the climate of Japan and also that of the west coast of North America from Alaska to the southern part of the United States. Not only does it modify their climatic conditions but also gives to those areas much greater supplies of moisture than they would otherwise receive. The similar currents of air and water crossing the Atlantic Ocean just above the equator force the current of warm water through the Caribbean Sea and the Gulf of Mexico and thence northward along the east coast of the United States and across the north Atlantic forming the "Gulf Stream," which carries warmth and moisture to northwest Europe. These currents of air and water from the vicinity of the equator affect climatic conditions and the productive powers of certain sections of the continents with which they come in contact and prove an important factor

in their production and contribution to commerce.

By these various conditions, the temperate and tropical climates, the differences of elevation, and the modification of climate due to air and ocean currents, nature has greatly diversified the production of the earth's surface, while she has also by other processes distributed beneath the surface the minerals which man has learned to utilize in the manufacturing industries and in transportation of the various natural products now so freely interchanged the world over. Within the last century man has learned to apply the power of steam and that of the waterfall in the form of electricity to the transportation of the great natural products of these various sections of the globe, and also to utilize these powers in transforming the natural products into the form required to make them useful to man. One hundred years ago there was not in all the world a steamship on the ocean or a mile of railway or telegraph on land. Now steamships seek their landing place at the frontage of every continent, and 700,000 miles of railway bring the products of the interior to the water's edge or receive that which the steamship has brought across the ocean and distribute it to the interior. One hundred years ago the world had less than 850,000,000 people; now it has over 1,900,000,000 with vastly greater producing and consuming power per capita than those of a century ago, and their vastly greater commerce, $68,000,000,000 per annum at the present time against $2,000,000,000 a century ago. Thus geography and geographic conditions, coupled with the power of transportation between the geographic sections and areas produce commerce, and in studying commerce we must study the geographic conditions which bring it into existence.

The value of the merchandise forming international trade was in the latest calendar year, 1929, about $34,000,000,000 or one-half of the usual statement of $68,000,000,000, which is obtained by counting the merchandise when exported from the various countries of the world and counting it again when it becomes an import in some other country. If we assume that the cost of transportation is about 5 per cent of the value of the merchandise transported we shall find that the world is paying $1,700,000,000 a year for mere carriage of the merchandise which it exchanges between the countries or continents, while the profits, legitimate or otherwise, of the millions of "middlemen" who handle the products in the passage from producer to the consumer thousands of miles from the place of production, are of course several times as much as the mere cost of transportation. Yet the people of the world ungrumblingly pay these billions of dollars every year for the sake of obtaining food, clothing, manufacturing material and manufactures accumulated from any and every part of the globe.

Trade between the climatic belts is very large irrespective of continental relationship. The tropical and sub-tropical areas of the world lie between the 30th parallel of north latitude which runs through New Orleans, Cairo and Shanghai and the 30th parallel of south latitude which falls a little north of Buenos Aires, Cape Town and Sydney, Australia. This tropical and sub-tropical belt around the world lying between the 30th parallel of north latitude and the 30th parallel of south latitude has one-half of the land area of the globe and half the world's population and it sells to the temperate zones at the north and south about $8,000,000,000 worth of its annual products.

Attention is especially called to the fact that only about one-half of the international trade of the world crosses the oceans. The other half is merely exchanges of merchandise between countries lying alongside each other or at least within the same continent. For example, the trade between the United States and the other countries of North America is, in normal years, one-third as much as that with all the other grand divisions of the world and the total interchanges of merchandise among the countries of North America are one half as much as their trade with the other continents. In Europe, the interchanges among the countries forming that continent are actually greater than their trade with all the other grand divisions of the world. The aggregate of the imports of all the countries of Europe in 1925 was $18,598,000,000 and of this large total only $8,000,000,000 worth was drawn from other grand divisions, the remaining $10,000,000,000 being trade between the countries forming that continent; and of the $14,408,000,000 of exports of all the European countries, only $4,000,000,000 passed "overseas" or out of that grand division, Europe, the remainder being exchanges between the countries of Europe and therefore intra-continental. The share of the aggregate trade of the European countries which occurs with other continents is about 40 per cent, in the case of Asia about 50 per cent, North America 66 per cent, South America, Africa and Oceania 90 per cent. North America sells to the other grand divisions $4,000,000,000 worth of her products annually, and buys from the other continents $3,500,000,000 worth. South American exports to the other grand divisions are over $1,770,000,000 a year, and her purchases from them range about $1,625,000,000, and in exceptional years as much as $2,000,000,000. Asia sends $3,792,000,000 worth of merchandise to the other grand divisions, and takes from them $2,985,000,000 worth of their products. Slightly more than one-half of the entire international trade of the world is intercontinental or exchanges between the continents or grand divisions, the remainder is intra-continental or exchanges between the countries of the continent in which the merchandise originates.

What are the principal articles which form the exchanges between the great geographic and climatic divisions of the world? Food, manufacturing material and manufactures. Man must have food, he must have manufactures and therefore he must have manufacturing materials. The countries having a dense population produce less food than their own people require and must import the remainder. The countries having a sparse population produce more food than their own people require and can export the surplus. The country having the surplus is willing to sell its surplus to the country having the shortage, if the latter has something with which to pay for it, and it usually happens that the country which must

buy food has a surplus of manufactures to sell, and as the new and less densely populated countries are not manufacturers, they are willing to take manufactures in exchange for their surplus food. If it is not convenient to make the exchange by the direct process, the purchasing country pays for the foodstuff in cash and the selling country takes the cash and buys its manufactures from a more convenient market. The manufacturing countries must also have manufacturing materials, and these they draw largely from the tropical and sub-tropical world, and as the tropical people are not manufacturers, they gladly accept manufactures in exchange for their natural products. They have also certain foodstuffs peculiar to the tropics, such as rice, sugar, coffee, cocoa, spices, fruits and nuts, which the temperate zone countries want and pay for in manufactures and in certain kinds of food which the tropics can not conveniently produce, especially flour and meat. In studying these natural exchanges and interchanges of commerce between climatic as well as continental sections, we therefore develop the study of commercial geography.

What have the respective geographic divisions to offer to the other parts of the world, and what do they respectively take in exchange? Europe has a population of 510,000,000 and an average of 145 persons per square mile; Asia, 57 per square mile; North America, 20 per square mile; Africa, 13 per square mile; South America, 12 per square mile, and Australia, 2 per square mile. Not only is the population of Europe much more dense than that of any other continent, but its people are much larger consumers per capita than those of certain other continents, notably Asia and Africa. So, it is quite apparent that Europe, densely populated as she is and having a population with a large consuming power, must draw large quantities of food from other parts of the world. That continent is also the largest manufacturer of the world, and with its dense population and closely occupied acres must draw much of its manufacturing materials from the other grand divisions. Europe as a whole produces in normal years about $65,000,000,000 worth of manufactures per annum out of a world total of about $150,000,000,000 of factory products, and supplies about $9,000,000,000 out of the $13,000,000,000 worth of manufactures entering international trade. For the food and manufacturing material which she requires, she draws chiefly upon North and South America, Australia and South Africa, and pays in manufactures and in the earnings of her ships and invested capital. North America, with a population of but 20 per square mile, has more of food and certain classes of manufacturing material than she requires; and although the United States is a large manufacturer and supplies three-quarter billion dollars worth of manufactures to her neighbors, the continent as a whole takes over a billion dollars worth of manufactures from Europe. South America, with a population of but 12 per square mile, has two billion dollars worth of food and manufacturing material to spare annually, and Europe gladly takes most of it and makes payment with a large proportion of her manufactures and the remainder in the services of her shipping and the earnings of her invested capital in that continent. This does not mean that all of the merchandise of South America goes to Europe, for parts of its wool and rubber and coffee go to North America, especially the United States. In Asia, with a population of 57 per square mile, the exportable surplus is small, and consists chiefly of silk, fibres, rubber, tea, coffee, tin, and certain other minerals, and for these she takes manufactures, chiefly from Europe, but in smaller quantities from the United States. In Africa and Oceania, the chief surplus is in tropical products and precious metals, though Australia and New Zealand supply large quantities of wool, meats and wheat, and all of Africa and Oceania take manufactures chiefly from Europe in exchange for the natural products above noted.

The tropical and sub-tropical world, while not a continent or grand division in the ordinary sense of the term, is in fact, a climatic division — a broad belt stretching around the world between the 30th parallel of north and south latitude already described. It supplies to the world about $8,000,000,000 worth of its products per annum, chiefly fibres, hides, rubber, coffee, tea, sugar and fruits, and takes manufactures in exchange, chiefly from Europe, but in limited quantities from the United States. Practically all of the surplus of the tropics is consumed in the temperate zone — chiefly in the United States and the manufacturing countries of Europe. The imports of tropical and sub-tropical products by the United States, including those from island possessions, increased from $335,000,000 in 1900 to over $2,400,000,000 in 1929.

While it is not practical to indicate in the limits of a discussion of this character the exact commercial relation of the various countries of the world to the various geographical sections, the broad extent of distribution, especially by the great industrial countries, is illustrated by the fact that the United States draws certain of its imports, especially manufacturing materials, from more than 75 different geographical or political divisions of the globe — continents, islands or countries and colonies — and sends certain of its products to more than 100 geographical and political divisions, extending to every part of the world.

OSCAR P. AUSTIN,
Statistician.

COMMERCIAL LAW. This term is rather loosely applied to a body of laws of the greatest diversity in their origin and character, but which have this in common, that they have arisen out of the usages of merchants and that the legislation and judicial pronouncements thereon have taken note of and embodied these usages. There is no better way of indicating what Commercial Law, or the Law Merchant, is than to enumerate the chief topics which it comprises. These are: Agency, arbitration and award, auctioneers, bailments, bankruptcy, common carriers, composition with creditors, corporations, factors and brokers, guaranty and suretyship, insurance, monopolies and restraints of trade, negotiable instruments, partnerships, patents, sales, trade-marks and warehousemen. The classification of Commercial Law here given is in substantial accord with that adopted in the French 'Code de Commerce' and in the German 'Handelsrecht,' although the French codification is more inclusive and

covers also the whole field of maritime law. The Law Merchant was regarded a distinct department of the common law and the word «trader» had once a technical meaning in English jurisprudence, being defined as «a person subject to the *lex mercatoria.*» Inferentially therefore, persons not traders were not subject to this law, and in the provisions of the English and American bankruptcy acts, limiting their applicability to merchants and traders, one may see a survival of the distinctiveness above referred to. The Law Merchant, however, was not an outgrowth of the unaided Anglo-Saxon genius. Commercial law was well developed among the civilized nations, which lived and flourished in Mesopotamia and the Euphrates delta from a period prior to 4000 B.C., and the Jewish bankers of Babylon and Nineveh had learned to deal in foreign exchange, their primitive drafts being inscribed in cuneiform letters on clay tablets. The commercial usages of remote antiquity, assimilated and added to by the Romans, were preserved by Venice and other trading communities of the Mediterranean during the period of the Middle Ages. A goodly part of the Law Merchant was absorbed into the common law of England directly from the Roman *Corpus Juris,* while some of it came indirectly, through the admiralty courts. It goes without saying, however, that a nation so active in world-embracing trade as the English would develop a mass of mercantile usages and of interpretive and regulative law on a subject of such momentous interest to it. And the statement that the English-speaking peoples, including the people of the United States, have made larger contribution to the body of commercial law during the past century and a half than all the rest of the world has contributed in half a millennium, is an indisputable fact.

One of the most original contributions of the Anglo-Saxon genius to the instrumentalities of commerce is the «goldsmiths' note.» This was a form of commercial paper issued by members of the Goldsmiths' Company of London against deposits of specie, the notes being payable to order of the depositor at a stated time and, when endorsed, they passed freely from hand to hand at face value. All that was needed was to make these promissory notes payable to bearer on demand, instead of to order and at a stated time, and to issue the same in the name of the guild instead of an individual member thereof, and the bank note was brought into being. This, indeed, was the genesis of banking currency. Out of the simple processes of transportation overland of freight and passengers, by wagons and stage coaches, arose the intricate and voluminous law of common carriers and its modern development, railroad law. The fundamental principles are few: A common carrier assumes absolute responsibility for the safe transportation and delivery of the goods and persons entrusted to his care; he is an insurer, and the fact that he has been guilty of no laches will not excuse him nor diminish his liability for losses. On the other hand, misrepresentation or concealment on the part of the shipper or owner of property carried, as to its character or value, constitute a fraud, vitiating the contract. The law gives the carrier a lien on any property entrusted to him to the amount of his claim to compensation for transporting and insuring the same while in transit; also any demurrage charges accruing through failure of the consignee promptly to accept the goods shipped and take them off the carrier's hands A common carrier may not discriminate between shippers in the rendering of services, nor in his charges for the same; he must receive and carry freight offered to the extent of his facilities, and may be compelled to increase facilities when the same are inadequate to the traffic. A bill of lading issued by a common carrier becomes an instrument of credit, acceptable as collateral and entitling the holder to the possession of the property billed on payment of transportation charges. The rights and obligations of warehousemen constitute important elements of commercial law. When a consignee unreasonably delays acceptance of goods shipped to him the common carrier is authorized to place them in storage, to be held subject to the carrier's lien and such further charges as may accrue in caring for and insuring the same. In many cases the warehouse, or some of the modern developments thereof, for example, cold storage and bonded warehouses, grain elevators and coal ports, are the intended destination of shipments *ab initio.* A warehouse receipt, unless it be specifically stipulated to the contrary on the face of the same, is a negotiable instrument.

The four main forms of commercial paper are the bill of exchange and its derivative the bank check, the promissory note and its derivative the bank note, the bill of lading and the warehouse receipt. Local usages have caused slight divergences in the law of negotiable instruments in the various States of the Union and other political subdivisions of the English-speaking world. Thanks to the efforts of the American Bar Association in propounding uniform State laws on this and related subjects, the inconveniences resulting from diversity are in the way of being remedied. From the latest *Report* of the proceedings of the Bar Association it appears that the uniform Negotiable Instruments Act has become a law in 46 States (Georgia and Texas being the exceptions) as well as in the territories of Alaska and Hawaii, the District of Columbia and the Philippine Islands; the uniform Warehouse Receipts Act has been accepted by 39 States, and the Bills of Lading Act by 20 States.

The greatest addition made to commercial law at one stroke by judicial authority was the statement of the law of Bailments by Lord Holt in the celebrated case of Coggs *vs.* Bernard, which is reported in 2 Ld. Raymond, page 909. What a large block of law this is will appear from a consideration of the fact that carriers, depositories (including banks), factors and brokers, innkeepers, pledgees, warehousemen and all other persons who borrow, hire or receive goods and chattels for selling, transporting or safekeeping, or for performing some work on or with the same, are bailees with respect to the property thus put into or left in their possession. The commission merchant who receives a consignment of goods to sell is a bailee, so is a banker who receives a note for collection; so is one who hires a team by the hour, day or week and, also, the tradesman who makes «pants» for «gents» from their own cloth or makes furs for ladies «from their own skins.» The word bailment is derived from the

Norman French, *bailler*, to deliver. Whatever is delivered by the owner to another person, in any of the ways or for any of the purposes above indicated, is bailed to him; and the law of Bailments comprises the rules and usages whereby the rights and duties of the parties in relation to the property and to each other are determined. Justice Holt, however, borrowed most of his principles, perhaps all of them, from the 'Institutes' of Justinian and the 'Corpus Juris Civilis.'

Under the subhead Arbitration and Award are embraced the rules of law and usages whereby merchants may obtain decisions of controversies between themselves without resort to the regular courts of law. An arbitrator is appointed by the parties on each side of the controversy and the two arbitrators select an umpire; whereupon the tribunal thus constituted proceeds with the hearing of evidence and the making of an award. The proceedings are informal and, while nobody can be compelled to arbitrate, when the parties have once submitted a case the submission is irrevocable, and the award made is enforcible just the same as is the judgment of a court of law. Some commercial exchanges, under special legislative authority, maintain courts of arbitration, presided over by permanent judges, who act either alone or as umpires in association with arbitrators appointed by the parties. Latterly efforts have been made to extend this method of adjudicating disputes among merchants internationally, and notable progress has been made toward an agreement between the Chamber of Commerce of the United States and the corresponding Argentine body at Buenos Aires. Composition with creditors is a common law method for the discharge of an insolvent debtor from his obligations. Usually the composition is preceded by an assignment of the debtor's property for the benefit of all of his creditors, with the object of preventing any creditor from obtaining a preference. All of the creditors must agree to the composition and the terms of settlement must be equal for all. If a single creditor, no matter how small his claim, refuses to sign the composition deed, or if by secret arrangement any discrimination whatsoever be made in favor of one or more creditors, the settlement is a nullity. To all intents and purposes compositions with creditors have been superseded by proceedings in bankruptcy (q.v.). Originally the law terms guaranty and warranty were of identical meaning. In time, however, "warranty" became employed exclusively as a term of assurance of the title, quality or quantity of a thing sold. Guaranty is an undertaking on the part of the guarantor to pay the debt or perform the obligation of another in the event of the latter making default. A guaranty, generally speaking, is not negotiable; nor is it transferable in such a way as to enable anybody except the party with whom the contract was originally made to maintain an action thereon. Regarding marine insurance as a subdivision of maritime law, the form of indemnity contract with which commercial law is chiefly concerned is fire insurance. This kind of insurance is sometimes made to indemnify against loss by fire of ships in port; more often this form of insurance is made to cover warehouses and mercantile property therein contained, or goods and chattels in stores and factories. The general principles of the law of contracts will answer most questions raised by fire insurance policies; but the analogies with marine insurance are many. A debtor, however, may insure his life for the benefit of his creditor. The law of agency rests on two fundamental principles: (1) The agent is a mere instrument, though a living and intelligent one; for, whether a man signs his name with a pen which he takes from the table, or by another man whom he requests or authorizes to sign for him, in either case the act is that of the principal; (2) as between the principal and a third party, the former is responsible for all the acts of the agent, if there was colorable reason for the belief of the third party that he was dealing with a principal or that the agent was duly authorized. Like the law of agency, the law of partnership and its modern outgrowths, the law of joint-stock associations and of corporations, are subjects too large for cursory treatment under the general head of commercial law. The modern law against monopolies and restraints of trade, though the same has become the subject of voluminous statutory regulations and judicial opinions, is a mere amplification of a few principles of the common law on the subject. The epochal opinion of Chief Justice White in the Standard Oil case was little more than a restatement of old and familiar legal maxims embodying commercial usages. The codification of the law of sales has been accomplished in England, but the Sales Act submitted to the National Conferences of the Commissioners on Uniform State Laws has, thus far, been ratified by only 18 States and Alaska Territory. The two controlling principles of the law of sales are: (1) That, where goods are sold by sample or according to description, there is an implied warranty that they correspond to the sample or description; (2) that in the absence of an express warranty the purchaser, having an opportunity to examine the goods, must be on his guard against defects.

In default of codification the Commercial Law as it exists in the United States must be sought under the titles of the subjects which it comprises. Even such a codification would be of little service to layman inexpert in the interpretation and construction of statutes. The hodge-podges published under such names as 'Business Laws' or 'Every Man his own Lawyer' are to be shunned as traps for the unwary. The saying that "a man who is his own lawyer has a fool for a client" is as true as ever. There are no short cuts to a knowledge of the law any more than there are to the knowledge of other sciences. Consult: Ayer, L. J., 'Cases on Business Law' (1927); Slater, J. A., 'Pittman's Mercantile Law' (6th ed. 1930); Sullivan, J. J., 'American Business Law' (1927); Parsons' 'On Contracts' (9th ed., 1909) or any other of the standard textbooks.

STEPHEN PFEIL.

COMMERCIAL LIFE INSURANCE. The primary purpose of life insurance is the protection of domestic relations. Obviously the proceeds of a life policy may serve at the same time to protect the insured's business interests when these are unexpectedly deprived of his directing hand and brain; but in recent years the agency of life insurance has been more

directly and broadly applied to commercial affairs. After providing suitably for the family by means of a policy made in their favor, an individual may provide guaranty for business credit beyond his tangible assets by means of a policy made payable to his estate; and copartners may provide against untoward disturbance of their joint capital and prospects by policies made in favor of the firm or of each other; while corporations may provide against loss through the untimely removal of experienced executive heads or of peculiar and essential talent by means of policies covering the lives of those on whom the company's prospects for the time depend. Owing to the immense development to-day of combined commercial interests and the consequent weight of responsibility resting on single lives, insurance running often to hundreds of thousands of dollars, and in some cases to millions, is now placed to safeguard the financial stability of corporate concerns or to indemnify them in case of the loss of service difficult or impossible to replace. The simpler business organization of a generation past called not often for such protection, but such is the peculiar genius, talent or experience involved to-day in many large enterprises that untoward removals in their personnel would cause serious if not irretrievable loss. Thus, on the one hand, commercial life insurance serves to aid in the development and stability of business by affording an additional guaranty for credit or for emergency loans, and on the other hand conserves business interests that might otherwise suffer from the loss of lives essential to their prosperity. The prediction is ventured by an authority that the life insurance policy will soon be an integral part of every considerable business arrangement. All the common forms of life policy are in use for commercial purposes, and the premium is considered an expense charge.

COMMERCIAL PAPER. A general name for checks, drafts, notes, bills of lading, bills of exchange, warehouse receipts, treasury warrants, orders for delivery of goods, certificates of stocks and bonds and sometimes loosely applied also to contracts and agreements. The term is intended to cover all that class of documents which are used commercially in place of money, and is therefore sometimes restricted to checks, drafts and notes.

Checks.— A check is an order on a bank, trust company or broker connected with a clearing house, calling for the payment of a specified amount of cash, from the funds of the maker on deposit, made to the order of some one named, or to "Cash" or "Bearer." It is frequently numbered, and written on a printed form blank, which may be on paper with a printed tint to prevent erasures. It is usually filled in with ink, and often the figures are also punched out of the paper or embossed so as to prevent alteration. It is good, however, if written in lead pencil, on any sort of paper. Its payment depends on the bank official's recognition of the signature, or his knowledge of and confidence in the party presenting the check for payment. Business houses seldom cash their checks, but deposit them as received, and draw their own checks for the payment of their bills. The check after payment is punched or canceled and eventually returned to the signer or maker, who thus secures a receipt which is positive evidence of the payment of the sum named, as the party receiving a check has to put his name on the back before it will be cashed or credited to his account. A check is payable whether dated or not, but if dated ahead is not payable until the date stated. To give a check dated ahead is sometimes necessary for a conditional transaction, but it is an improper proceeding unless the cash is in the bank. When a bank is asked to certify a check, it will do so, if the funds are there to the credit of the maker, and it then becomes primarily liable, and the sum no longer remains to the credit of the signer of the check. Checks are usually printed in quantities in blank and bound in books with stubs, on which may be kept a record of the transactions. Banks have to pay all the checks they handle or make themselves liable for them; but they turn the checks over daily to a clearing house, which figures out the balances due to or receivable from each bank, and settles only the balances in cash. This system relieves each bank of the immense detail of collecting each individual check.

Drafts.— A draft is very similar in form to a check, but it is an order from one bank to another bank to pay a sum stated to the party in whose favor it is made. A small merchant in a small town, who is not known, desiring to send a payment to a large city house and secure immediate shipment of the goods he orders, gets from his local bank a draft on a city bank, and uses this instead of his own check. The city merchant receiving such draft can cash it at once, knows that it is good, and has no hesitation in shipping the goods. A sight draft is an order drawn by a party to whom money is due, for the payment of money by another party at a bank named, and sent through the bank for collection. If the party to whom it is addressed through the bank pays it, it is said to be accepted.

Bills of Lading, etc.— A bill of lading or a warehouse receipt is a receipt from a transportation company or warehouse showing that the goods specified have been delivered to them. Such bills are often commercially important, being frequently used as a basis for borrowing money. Wholesale merchants sometimes handle goods vastly in excess of their capital, but through borrowing on such receipts secure funds for transacting a large business.

Notes.— A promissory note is a promise to pay a specified sum on demand or at a future date. (See PROMISSORY NOTE). The signer of a note, draft or check is the drawer or maker. The one to whom payment is to be made is the payee. One who signs on the back is an endorser, and he thus guarantees the payment. To hold an endorser liable for the non-payment of a check or note, he must receive prompt notice. There may be several endorsers. A release by the holder of a note to one endorser releases all other endorsers.

Money Orders, etc.— In the United States these are issued at nearly all post-offices by the postmaster for amounts up to $100, on payment of a fee of 3 cents for $2.50 or less and up to 30 cents. They are payable at the post-office named or can be banked for collection for $100

Express orders are also issued by express companies for moderate amounts and are payable at any office of the company, or can be banked like ordinary checks.

Certificates of stocks and bonds that have recognized value may be deposited with banks as collateral security for loans. See NEGOTIABLE INSTRUMENTS; BANKS AND BANKING (Article 17).

COMMERCIAL POTASH. See POTASH, COMMERCIAL.

COMMERCIAL REVOLUTION AND DEMOCRACY. See DEMOCRACY, HISTORY OF.

COMMERCIAL TERMS. The following list is practically a short dictionary of the terms used in commercial or business life. As it is manifestly impossible to include all the terms applied in this relation, care has been taken as far as possible to omit those that may be ordinarily regarded as self-explanatory. Some of the more important terms are defined more fully under their respective headings.

ABANDONMENT.— Used in the customs when an importer abandons his property to avoid paying duties upon it.

ABATEMENT.— A creditor's voluntary reduction of his claim.

ABBROCHMENT.— The act of controlling the market by monopolizing goods.

ACCEPTANCE.— An engagement to meet a draft or bill of exchange. To make it legally correct the person against whom the bill is drawn must write his name across its face. Sometimes the word "Accepted" written above the name, is also insisted upon. An acceptance is "clean" when no qualification is affixed and "qualified" when some modification accompanies the signature.

ACCEPTOR SUPRA PROTEST.— A person who, while not a party to a bill of exchange which has been protested, engages to pay it if the drawee does not.

ACCESSORY CONTRACT.— An engagement made to secure the observance of a prior contract; sometimes by the same parties; sometimes by others, as in the case of suretyship, etc.,

ACCESSORY OBLIGATION.— An obligation that is subordinate to another obligation, as when a mortgage is made to secure the payment of a bond.

ACCOMMODATION.— A term usually used to denote pecuniary aid in time of emergency.

ACCOMMODATION BILL.— A note, or bill of exchange, not founded upon a prior debt, but endorsed by one or more responsible parties that others may obtain credit on it.

ACCOUNT.— (*a*) A record of money transactions, as with a bank; (*b*) in business, the statement of debits and credits, with balance on hand, or due; (*c*) on the stock-exchange, a transaction to be settled on the regular settling-day.

ACCOUNT CURRENT.— A detailed account of business dealings still continuing between specified parties. Sometimes called an open account.

ACCOUNT SALES.— An account rendered by a broker or commission merchant to his principal, specifying the goods sold, prices obtained and the net result after the deduction of commissions, expenses, etc.

ACCOUNTABLE RECEIPT.— The form of receipt given when the money or goods received are to be accounted for.

ACCRUED DIVIDEND.— The proportion of dividend not yet due, computed to a date prior to the time set for payment, or the elapsed time since the last previous payment.

ACCRUED INTEREST.— The amount of interest not yet due computed to a date prior to the date of payment.

ACCUMULATED DIVIDEND OR INTEREST.— Dividend or interest past due and unpaid.

ACQUITTANCE.— An acknowledgment in writing that a debt has been paid.

ACTIVE.— A term used to denote brisk, or lively trading, as: an active market.

ADULTERATION.— The act of debasing goods by admixture with other substances. When performed to meet the tastes and demands of the public it is called "conventional" adulteration; when done with intent to deceive it is "fraudulent" adulteration; when through carelessness it is known as "accidental" adulteration.

AD VALOREM.— According to value. Usually applied to duties levied by the customs.

ADVANTAGE.— Another term for usury; (*b*) the thirteenth article added to make what is commonly known as the baker's dozen.

ADVICES.— A notification respecting mercantile transactions especially in the dispatching of goods.

AFFREIGHTMENT.— The act of hiring a ship in which to transport goods.

AGAINST.— Used in commerce in reference to a balance, as when an exporter draws against the merchandise he has shipped.

ALL-AROUND PRICE.— A price which includes all charges and costs.

ALLOCATION.— Allotment, as of stock or bonds to bidders.

ALLONGE.— Sometimes called a rider. A paper attached to a note, or bill of exchange to receive endorsements for which there may be no room on the back of the bill.

ALLOTMENT.— The act of dividing a ship's cargo into separate portions that they may be assigned by lot to different purchasers.

ALLOTMENT CERTIFICATE.— The memorandum issued to an applicant for stock, showing the number of shares alloted, etc., as well as the dates on which the payments are to be made.

ALONGSIDE.— Delivery of goods at the side of the vessel on which they are to be loaded.

AMORTIZATION.— A term used chiefly to denote the extinction of a debt by a sinking fund.

APPRAISEMENT.— Chiefly used to denote the value placed upon special articles by disinterested person.

APPRECIATION.— An increase in the value of property — as of real estate.

ARBITRAGE.— A branch of the stock exchange business, its transactions being based upon the temporary difference in the price of securities in two markets, the purchases being made in the cheaper, the sales simultaneously in the dearer market. As applied to exchange it is called arbitration.

ARTICLES OF ASSOCIATION.— The document containing the internal regulations of an incorporated company with all the laws by which its affairs are conducted.

ASSESSMENT.— Used on the stock exchange to denote the sum charged against stockholders to pay debts of a corporation.

ASSETS.— The entire property, both real and personal, that may be devoted to paying the debts of the person, estate or corporation.

ASSIGNMENT.— The transfer of title or interest in property; chiefly used when the transfer is made for the benefit of creditors. The term is applied both to the action and to the document making said transfer.

ATTACHMENT.— A legal process directing that the person or estate of a person be taken and held by an officer of the court to secure a debt, or demand, etc.

AUDIT.— Official verification of accounts and claims made to prevent fraud on the part of the person keeping the books.

AVERAGE.— (1) As applied to a series of accounts, the date at which the whole sum due may be regarded as payable; (2) The charges, over and above freight charges, paid to the master of a ship for his personal attention to the care of the goods. The small charges paid by the master for pilotage, towage, etc., are specified as "petty average."

AVERAGE ADJUSTER.— When a loss is to be divided between several interested parties the expert accountant who ascertains and states the sum to be paid by each person is called the average-adjuster, or average-stater.

BACK SPREAD.— An arbitrage in which the price in either market is less than the price in the other plus the transportation charges.

BALANCE.— The sum required to equalize the debit and credit sides of an account. If added to the debit side it is a credit balance, and vice-versa.

BALANCE OF TRADE.— The difference shown between the total value of a country's annual exports and imports.

BALANCE SHEET.— A condensed statement showing the financial condition of a business.

BANK BILL or BANK DRAFT.— A bill or note drawn by one bank upon another and payable according to specifications.

BANK CREDIT.— An arrangement by which, upon the giving of proper security, a person is permitted to draw to a specified extent upon the bank's funds.

BANK NOTE.— A promissory note by which the bank of issue agrees to pay its face value to bearer on demand. In the United States and Canada, where these notes are issued only by banks authorized by law, such paper passes as currency.

BANK RATE.— The rate of discount established by the banks. The term is used generally in reference to the rate established in foreign countries by the government banks.

BANKRUPT.— A person who, having become insolvent, or unable to pay his debts in full, is adjudged a bankrupt by the court, either upon his own application or on that of his creditors.

BAR.— Commercially a bar is an ingot, or lump of gold or silver, run in a mold, but still unwrought.

BEAR.— In the stock exchange the term denotes a person who sells stocks or shares that he does not possess for future delivery in the expectation that he will be able to buy them, in the meantime, at a lower price.

BEAR MARKET.— A condition of the stock market in which prices are tending downward.

BILL.— A written statement of goods delivered or services rendered with the amount of money charged for the same.

BILL-BOOK.— A book in which the merchant keeps the detailed record of promissory notes, bills of exchange, etc

BILL OF ADVENTURE.— A document by which a master or ship-owner shows that the goods shipped on a vessel are at the venture of another person, he being responsible only for their delivery.

BILL OR LETTER OF CREDIT.— A letter requesting that credit in goods or money be given to the bearer.

BILL OF ENTRY.— A written statement of goods entered at the custom-house.

BILL OF EXCHANGE.— A written order to pay on demand, or at some specified time, a certain sum of money to a specified person, or his order; usually in foreign commercial dealings.

BILL OF HEALTH.— An official certificate showing the condition of a ship's company at the time of her clearing port. Such bills are termed "clean," "suspected," or "foul," according to conditions prevailing, both on the ship and at the place from which she cleared.

BILL OF LADING.— A receipt for goods delivered to a common carrier for transportation. Usually applied to goods delivered to a railroad or on board ship.

BILL OF SALE.— A contract by which an absolute or conditional transfer of goods is made; often given as a security for debt.

BILL OF SIGHT.— A custom-house entry which permits the importer to inspect goods before they are officially accepted.

BILL OF STORES.— A license granted by customs officials by which merchant vessels are permitted to carry stores and provisions for their voyage free of duty.

BILL OF SUFFERANCE.— A license authorizing coasting vessels to trade from port to port without the payment of customs duties. Under such license all goods must be loaded and landed at sufferance wharfs.

BILLS PAYABLE AND RECEIVABLE.— Bill of exchange, promissory note or other commercial paper. The person who is to pay it terms it a "bill payable," the person who is to be paid holds it as a "bill receivable."

BLANK ENDORSEMENT.— An endorsement without direction as to whom the funds are to be paid: the bearer then becomes the owner.

BLIND POOL.— A fund contributed by several persons and placed in the hands of one for secret investment.

BLOTTER.— Called also the day-book: the running record of a business.

BOARDING-OFFICER.— A custom-house official whose duty it is to board ships upon their arrival, to examine papers and prevent smuggling.

BOND.— (*a*) An instrument by which the maker binds himself to perform a specified act; (*b*) a surety; (*c*) goods or merchandise left in charge of custom-house or excise officers.

BONDED DEBT.— An obligation contracted under and secured by a bond.

BONDED WAREHOUSE.— Often called "public" or "bonded stores." A building in which goods or merchandise is stored pending the payment of customs duties or excise tax.

BONUS.— (*a*) A premium for a loan; (*b*) an extra-dividend or allowance paid out of accumulated profits; (*c*) an honorarium, or extra sum paid voluntarily as a reward for successful efforts or as a stimulus to extra exertions.

BOOK-ACCOUNT.— In double-entry bookkeeping, an account showing transactions in some particular commodity, without reference to the individual with whom they may have been effected.

BOOK VALUE.— The value of stock as based on the records of the company as distinguished from the market price.

BOOTHAGE.— The sum charged for the right to erect booths at fairs or in market places.

BOTTOMRY.— The mortgage of a vessel to secure a loan.

BOUGHT AND SOLD NOTES.— Contracts issued between brokers at the conclusion of arrangements for sales or purchases. Also called "Contract notes."

BOUNTY.— A premium or reward offered by a government to encourage some particular branch of industry.

BOURSE.— The name applied to the stock exchanges, or money markets of Continental Europe.

BROKER.— The middleman who negotiates the purchase or sale of stocks, commodities, etc., for others, accepting a commission, called "brokerage," in return for his efforts. There are many classes of brokers, the following being examples: Bill-brokers, insurance brokers, cotton brokers, stock exchange brokers, curb brokers, ship brokers, etc.

BROKER'S NOTE.— A voucher containing the particulars of a transaction delivered by a broker to his principal.

BUCKET SHOP.— While nominally established for the conduct of a stock exchange business, the fact that there are neither transfers nor deliveries of the stocks or commodities dealt in has led the courts to determine that its transactions are nothing more than gambling wagers.

BULL.— On the stock exchange, one who purchases stock for future delivery, expecting to sell at a higher price before the time of settlement.

BULLION.— Chiefly used to denote uncoined gold and silver in bars and other forms. Bullion value is the market value of the metal in coins as metal.

BUYER FOUR (or Ten, Twenty, Thirty or Sixty) — refers to the number of days during which a buyer of stock may elect to demand its delivery upon 24 hours notice. The period may not be less than 4 days nor more than 60 (New York Stock Exchange). Buyer the Year is permitted on some exchanges.

BY-BIDDER.— A person employed to make fictitious bids upon goods sold at auction, to secure higher prices for the owner.

CALL.— (*a*) A privilege secured by contract and a consideration, of claiming and receiving either a certain number of shares of some particular stock at a stated price and within a given period, or the difference in value between the date of the demand and the date of the contract. (*b*) A notice of withdrawal of bonds, upon receipt of which holders must present them and receive payment of the principal and whatever interest may be due. (*c*) An assessment upon stockholders to pay instalments or losses.

CALL LOAN, or CALL MONEY.— Money loaned on condition that it may be recalled at any time.

CALLED BOND.— A bond called in by the maker for the purpose of payment. A bond ceases to earn interest when it is called.

CAMARAGE.— The rental paid for a storage house.

CANCEL.— A bill, or bond becomes void when the word "Canceled" has been written across it, or the signatures punched out or cut.

CARRIER.— One who conveys goods or persons for hire. A "common" carrier carries as a business; a "private" or "special" carrier, by special agreement.

CARRYING CHARGES.— Interest paid by purchasers of stocks on margin, on the difference between the market price of the stock bought and the amount of margin deposited to hold ownership in it.

CASH.— A term ordinarily applied to coin, and other currency, although readily negotiable securities are sometimes included. The term "hard cash" is also frequently applied to money actually in hand.

CASH ACCOUNT.— An account of money transactions: receipts, payments and balance on hand; (*b*) a term used in banking to denote the credit given to depositors on receipt of a properly secured bond for the repayment of the amount advanced with interest.

CERTIFICATE OF DEPOSIT.— A negotiable receipt issued by a bank upon deposit of money. The legal possession of the certificate carries with it the ownership of the money deposited.

CHARGE.— (*a*) To fix as a price; (*b*) to set down at a price; (*c*) to enter on the debit account.

CHARGES FORWARD.— The accumulated expenses of goods in transit to be paid on delivery. They may include the purchase price also.

CHARTER.— (*a*) A document given in evidence of a government grant conferring privileges on the fulfilment of specified conditions; (*b*) the hiring of a ship by special contract.

CHARTER PARTY.— The written agreement under which a vessel is leased.

CHECK.— To all intents a check is practically a bill of exchange, payable on demand, being a written order for money previously deposited with a banker. When a check has been endorsed by the payee, and paid to a third party it loses its claim against the endorser if not deposited or mailed for collection by the day after its receipt by the holder.

CHOP.— An exporter's brand, representing a certain definite quality of goods.

C.I.F.— Cost, insurance and freight (q.v.).

CIRCULAR NOTE.— A letter of credit issued on foreign firms by bankers to travelers.

CIRCULATING MEDIUM.— The recognized means of making payments.

CLEAR DAY.— A business day intervening between the day a transaction is entered upon and the day it is concluded.

CLEARANCE.— An official document certifying that a vessel leaving for a foreign country has complied with the laws of the port sailed from.

CLEARING.— A term used in several branches of trade, and usually to denote different actions. A vessel is "cleared" when it has furnished all particulars about its crew and cargo when about to leave port. In importations goods are "cleared" when all duties and dues have been paid. In banking, "clearing" is a term applied to a plan by which checks and bills are exchanged daily.

CLEARING HOUSE.— An institution where local banks meet daily to settle their mutual claims. Its certificates of deposit are negotiable only between members of the association.

COLLATERAL SECURITY.— Any property given to secure the performance of a contract and that is to be surrendered upon the performance of the latter.

COMMERCIAL PAPER.— Drafts, bills of exchange and other negotiable paper given in the course of business.

COMMUTATIVE CONTRACT.— A contract in which each of the parties interested gives and receives an equivalent.

COMPOSITION.— The sum, or rate agreed upon in compounding with creditors. When a contract is signed by which the creditors agree not to molest their debtor the document is termed a "composition deed."

COMPOUND INTEREST.— Interest paid not only on the principal but on the interest that accumulates thereon, the latter being added to the original amount.

CONCESSION.— A grant or privilege made by governments to individuals to encourage them in carrying out undertakings that promise to be mutually beneficial.

CONFIRMATION.— A document remedying a defect or supplying an omission in a contract.

CONDITION OF SALE.— A written statement of the particular terms under which property may be sold at auction.

CONSIGNMENT.— Goods sent for sale or delivery according to agreement. The sender is called the "Consignor;" the recipient, the "Consignee."

CONTENT.— A term used in the customs to denote the paper given by the master of a vessel before she clears outward. It details the vessel's destination, describes goods shipped, etc.

CONTRABAND.— Goods exported or imported contrary to the laws of the country concerned.

COOKED.— A term used to stigmatize a report or accounting which has been intentionally made deceptive.

CORNER.— Commercially the term is used to denote the fact that some person or clique has purchased so largely of a certain stock or commodity for immediate and future delivery that nearly the whole available supply had been monopolized.

CORPORATION.— A company of individuals whose acts are recognized by law as those of a single person. A corporation which fills its own vacancies is known as a "close" corporation.

COST, INSURANCE AND FREIGHT.— Items of expense sometimes grouped to make the purchase price of goods — said to be sold c.i.f. In such case the carrier becomes the agent of the buyer, and delivery to the carrier is construed delivery to the buyer.

COUPON.— A warrant for the payment of interest or dividends that may be detached from bonds and presented for collection when such payments fall due. The expression "coupon off" means that the current interest has already been collected; "coupon on," that it is still to be collected.

COVERING SHORTS.— The term "to cover shorts" is used in the stock exchange to denote the fact that some person has bought in such stocks as he had previously sold short to enable him to meet his engagements or to protect himself against loss.

CREDIT.— A term applied when goods are sold upon the understanding that they are to be paid for at a future date. The time given for such payment denotes whether the accommodation shall be known as a "long" or a "short" credit.

CURRENCY.— The legal coinage, or any form of money which is current as a medium of exchange.

CUSTOMS DUTIES.— The tax, or duty imposed by law upon the exportation or importation of merchandise.

CUTTING A MELON.— A distribution of extra dividends of money or stock to shareholders in an enterprise.

DAYS OF GRACE.— The number of days which may expire after payment is due before said payment may be demanded. In the United States and Canada three days of grace are usually allowed, except on "demand" or "sight" paper although some States, like New York, have abolished all grace in the payment of obligations.

DEAD-PLEDGE.— Lands or goods pawned, or pledged.

DEBENTURE.— (*a*) A deed given by a corporation as an evidence of debt which may be negotiated like any other investment paper; (*b*) in the customs the term is used to denote a certificate of drawback indicating that the holder is entitled to a refunding from the government on the re-exportation of goods upon which the duties have been paid.

DEBIT.— That which is entered upon an account as a debt.

DEFERRED BONDS AND SHARES.— Bonds on which the payment of interest does not begin till some future date. Holders of "Deferred shares" do not participate in the profits until the expiration of a specified time.

DEL CREDERE.— An additional commission paid to a factor, or agent when he binds himself to be responsible for the transaction of business, but also to guarantee the solvency of those with whom he contracts.

DELEGATION.— A term used in banking to denote a non-negotiable letter employed by bankers in transferring a debt; also, a third person substituted for the original debtor in a transaction.

DEMURRAGE.— A charge made as compensation for the detention of a freighter in loading or unloading; also applied to railroad cars so detained.

DEPOSIT.— (*a*) A sum of money placed with bankers for credit under agreed conditions; (*b*) partial payment on goods before delivery as a security for the order.

DEPRECIATED MONEY.— Money which will not exchange for its face value in gold coin.

DIFFERENTIAL.— A transportation rate made lower for a less advantageous route, in order to equalize attractions for business.

DISAGIO.— The percentage retained by a banking house for exchanging foreign money.

DISCOUNT.— Allowance made on bills paid before they are due; also interest collected in advance, as in discounting notes. The term "At a discount" implies that an investment is below par. "Discount day" in banking is the day set apart for the discounting of bills or notes.

DISHONOR.— When acceptance of a draft is refused; or when an acceptor fails to pay a bill when due it is said to be "dishonored."

DIVIDEND.— (*a*) An individual share of profit due upon an investment. (*b*) The payment made by a bankrupt to creditors in adjusting the difference between his assets and liabilities.

DOCUMENT BILL.— A bill of exchange accompanied by such security as a bill of lading, an insurance policy, etc., given in return for an advance in money.

DOLLAR EXCHANGE.— Exchange drawn in dollars and cents to be paid in a foreign country; or drafts drawn in a foreign country to be paid in dollars in America.

DOMICILED.— A term applied to a note or draft made payable at a designated place.

DRAFT.— A term used in many connections, but usually as a bill of exchange. A draft requires acceptance by the person on whom it is drawn. The drawer assumes no liability for the draft when making it; as he does when making a check.

DRAWBACK.— Duty paid on imported goods refunded because of re-exportation.

DUE BILL.— A cashier's check issued by a bank in lieu of the usual form of certification, the original check being retained by the bank holding the account.

E. & O.E.— An abbreviation of "errors and omissions excepted." By the affixing of these letters to an account, the right to correct it is reserved.

EARNEST MONEY.— Money paid to bind a bargain.

EMBARGO.— An official seizure of ship or merchandise to prevent its removal from port.

EX.— As used in combinations ex-dividend or ex-interest means not including the accrued interest or dividend.

EXCHANGE.— (*a*) To part with in return for an equivalent; (*b*) a place where merchants, brokers, etc., meet daily to transact business.

EXCHANGES.— The checks, drafts, etc., on any bank presented for payment through the clearing house.

EXCISE.— The tax imposed upon certain articles of home production. Also called the "Internal Revenue tax."

EXTENDED.— Applied to a bond which is continued after maturity for a certain period.

FACTOR.— A selling agent to whom is given possession of goods to be sold — in distinction from a broker who does not have the goods.

FAT LOAN.— A loan secured by an overplus of collateral.

FIDUCIARY CAPACITY.— A relation of trust and confidence. Thus a "fiduciary loan" denotes a loan granted without other security than confidence in the borrower's honor.

FISCAL YEAR.— Any 12 consecutive months covering financial operations, as distinguished from the calendar year. The fiscal year of the United States extends from 1 July to the following 30 June.

FIVE PORTS.— An exporter's term referring to Boston, New York, Philadelphia, Baltimore and New Orleans.

FLAT.— Without interest.

FLOATING CAPITAL.— Money tied up temporarily in raw material and partly manufactured goods, wages, etc.;— as distinguished from *fixed* capital, invested in buildings and machinery.

FLOATING DEBT.— An unfunded debt.

FLOTSAM.— Goods from a wreck that are found floating.

F.O.B.— Free on board;— all expenses paid to and including the loading of freight on cars or vessel.

FORCE MAJEURE.— Circumstances that are beyond human control.

FORECLOSURE.— To deprive a mortgagor of his right to redeem the property mortgaged.

FORWARDING NOTE.— A descriptive note sent by the consignor with goods conveyed by carrier.

FOUR PORTS.— The four principal ports on the Atlantic coast — Boston, New York, Philadelphia and Baltimore.

FOURTH WEEK.— In railroad accounts, all the days of a month remaining after the 21st, numbering 9 days in months of 30 days, and 10 days in months of 31 days.

FRAUGHT MONEY.— Money paid for the transportation of goods.

FREE ALONGSIDE.— The purchase price for goods sold under this condition includes their delivery alongside of a designated vessel; at which juncture the seller's responsibility ceases, and the buyer's begins.

FREE OVERSIDE.— The purchase price of goods thus sold includes delivery out of the hold of a vessel upon a lighter, or upon a dock. When so delivered, the seller's responsibility ceases.

FUNDS.— The accumulation of money, or its equivalent, devoted to, or available for the maintenance of some business or institution, or for some other specific purpose.

GOODWILL.— The value supposed to attach to an established business connection.

GROSS.— (*a*) Weight and amount without deduction for any purpose; (*b*) 12 dozen, or 144 articles.

GUARANTEE.— An engagement to fulfil another person's obligations provided he fail to do so.

HEDGING.— Guarding against loss by purchasing against a previous sale or selling against a previous purchase, not necessarily in the same security.

HONOR.— To meet a claim, or obligation at the time when it is due.

HYPOTHECATION.— (*a*) The act of pledging, by delivery or otherwise, stocks, bonds, etc., as security for obligations; (*b*) the mortgage of a vessel or her cargo.

IMPOST.— A government tax or duty laid on goods imported.

INDENTURE.— A sealed agreement between two or more parties.

INSOLVENT.— A person whose assets are insufficient to enable him to meet his liabilities.

INTEREST.— The sum paid for the use of money or the profit derived from the employment of capital.

INVESTMENT.— A sum of money expended with the hope of making profit. As applied to securities, it signifies those bought outright and not on margin.

INVOICE.— An account sent to the buyer or consignee of goods, in which the seller gives details respecting quantity and price.

JETSAM.— Part of a ship's cargo that sinks in time of wreck.

JOINT STOCK COMPANY.— An association the merabership in which is attained by the purchase of stock which is issued in shares.

JUDGMENT NOTE.— A promissory note to which a power of attorney to appear and confess judgment for the sum named has been attached.

KILLING.— A very large profit made as the result of a "corner," or a condition of panic.

LAKE-AND-RAIL.— Signifying transportation in part on the Great Lakes and in part by railroad; used generally as to a combined rate for such service.

LAMB.— A term used in the stock exchange to denote an inexperienced person who has made losing investments.

LAY-DAYS.— The stipulated number of days allowed to a charterer for the shipping or unloading of a vessel.

LEASE.— The grant of temporary possession, as of lands or tenements, for a fixed compensation, and a specified length of time. The person granting this right is called the "Lessor" the person accepting the grant is the "Lessee," or "Leaseholder."

LETTER OF ADVICE, or simply, ADVICE.— A notification of the fact to a party upon whom a bill of exchange has been drawn.

LETTER OF CREDIT.— A document, usually issued by bankers, authorizing their agents to pay a sum of money to the bearer.

LETTER OF DELEGATION.— See DELEGATION.

LIGHTERAGE.— The sum paid for unloading a ship's cargo by means of a lighter, or barges, and delivering it at a dock.

LIMITATION.— Many statutes fix a period after which debts cannot be collected. This period of limitation ranges in the different States from 6 to 20 years.

LIMITED LIABILITY COMPANY.— A concern the shareholders in which cannot be held responsible for the company's debts for more than the nominal value of their own shares.

LIQUIDATION.— The act of winding up a business, or extended transaction.

LOCUM TENENS.— One who temporarily holds the place of another.

LONG.— Having a large supply. A speculator is "long" of a certain stock when he has bought it largely.

MANIFEST.— A statement giving full details as to the items of a cargo and its consignees prepared before the sailing of a ship.

MANIPULATION.— Fictitious sales and purchases of stock through two allied brokers, at constantly rising or falling prices, for the purpose of creating an appearance of activity at the new prices.

MARGIN.— The percentage deposited by a speculator with the broker who buys or sells stock for him. This money is forfeited to the broker if the stock so rises or falls as to absorb it. The usual margin demanded is from 5 to 20 per cent on the face value of the stock dealt in.

MATCHED ORDER.— An order to sell and buy the same stock. See MANIPULATION.

MATURITY.— The time at which notes, drafts, etc., become due.

MEASUREMENT GOODS.— Light goods which are charged for carriage by bulk instead of weight.

MEMORANDUM SALE.— The act of sending goods to a proposing buyer subject to his approval, title vesting in the intending seller until they have been accepted.

MORATORIUM.— A special enactment of a government deferring the time at which the payment of debts may be demanded for a certain specified period.

MORTGAGE.— A method of pledging property for debt in which the lender may foreclose upon the security if the interest agreed upon is not maintained.

NEGOTIABLE PAPER.— An evidence of debt which can be transferred by indorsement to another.

NET.— The sum remaining, after all deductions for expenses, costs, etc., have been made.

NON-CUMULATIVE STOCK.— Stock on which dividends accumulate only when declared.

ON MEMORANDUM.— At a secret price agreed upon between the buyer and seller.

OPEN ORDER.— An order which is in force until countermanded.

OPTION.— The privilege of either receiving or supplying specified goods or stocks at a stated price agreed upon by the buyer and seller.

OUTLAWED.— As applied to a claim means that the time within which suit may be brought under the law has expired. In New York State the limit is six years from the time the last payment of interest was made.

OVERDRAWN.— A bank account is said to be overdrawn when checks amounting to more than the balance of the account have been drawn against it.

PAR.— The face value of shares or bonds.

PASS BOOK.— A small book issued by bankers in which to show the receipts and payments made on a customer's account.

PASSED DIVIDEND.— Omission to declare a dividend at the accustomed date.

PER PROCURATION.— Abbreviated commonly to "P.p." meaning, by power of attorney — of the person whose name follows the two initials.

PERMIT.— The written authority to remove goods on which duty has been paid from the custom-house is called the revenue officer's "permit."

PIKER.— One who trades in stocks in small lots.

PINHOLED.— Exhibiting many pinholes — indicating, in the case of a certificate of stock, that it has changed owners several times, and is therefore of a speculative character.

POINT.— In the price of stocks a point is 1 per cent; in cotton and coffee a point is 1-100 of one cent.

POOL.— A combination of mercantile and manufacturing interests to regulate production and prices.

POSTDATED.— As applied to a check, a date in the future. The check cannot be legally paid before the date it bears.

PREFERRED CREDITOR.— A creditor whose claim under the law takes precedence of payment over other claims.

PREFERRED STOCK.— Stock upon which the dividends are first paid out of the earnings: what remains is paid to the common stock. Generally the preferred stock receives a certain designated percentage, and it may happen that the overplus will give the common stock a much larger dividend.

PREMIUM.— When shares or bonds are quoted above par they are said to be "at a premium."

PRICE CURRENT.— A list published by a merchant showing the prices at which goods are to be sold for a fixed period.

PRICE MARK.— The secret code of letters used in marking goods. One or more words are chosen having just 10 different letters, which are used to indicate the numerals 1 to 9 and 0. Supposing the code words are "white sugar," a price of $1.25 would be represented by whe; a price of $0.70 by ur; etc.

PRICE OF MONEY.— The rate of discount at which money may be borrowed.

PRIME COST.— The first, or original cost of an article.

PRO FORMA INVOICE.— A statement of the condition of the market issued for the information of a prospective buyer. It may be presented in lieu of a formal invoice at the custom-house, where, if duly verified, it is accepted as a substitute.

PROCURATOR.— The person who is empowered to act for another.

PROCURATION-FEE.— The sum taken for effecting loans of money.

PRO RATA.— To distribute proportionally.

PROMISSORY NOTE.— A written agreement to pay a specified sum of money at a certain time.

PROOF IN BANKRUPTCY.— An affidavit in which a creditor declares that his claim to bankrupt's estate is correctly stated.

PROTEST.— The certification by a notary that a note or bill of exchange was presented for acceptance or for payment, and the proper disposal refused. The protest binds the endorsers; without it, they are released from liability.

PROXY.— A term applied both to the person who acts for another and to the document that gives him the power to act.

PUTS.— An option to deliver certain stock at a certain price at a future date. A term used in stock exchange speculation.

PYRAMIDING.— The speculative process of using the profits on stocks bought on margin in a rising market to buy other stocks also on margin. The term is applied also to selling on a declining market.

QUALIFIED ENDORSEMENT.— An endorsement prefixed by the words "without recourse to"—signifying that the endorser simply passes his title to the paper, but disclaims responsibility for payment.

QUOTATION.— The prices at which goods are offered. Stock quotations are given in eighths of 1 per cent; cotton and coffee in 5-100 of one cent; pork, lard, and grain in eighths of one cent.

RATE OF EXCHANGE.— The sum given in one country's currency for the currency of another country. Rates of exchange fluctuate widely, being subject to many influences.

RATING.— The estimate of the financial soundness of a person or firm — as given by a qualified commercial agency.

READJUSTMENT.— A voluntary reconstruction of the finances of a company: when the reconstruction is compelled by a court action, it is termed a reorganization.

REBATE.— A discount given by the bankers in return for ready-money payments.

REGISTERED BOND.— A bond bearing the name of its owner and recorded as his property. The interest on such a bond is payable only to the registered owner. When the ownership is transferred, a new bond is issued to the new owner.

RESERVE.— The sum kept for the purpose of enabling the holder to meet special contingencies.

SACK.— In the United States a "sack" of flour signifies 140 pounds; in Great Britain, 280 pounds.

SALVAGE.— A term applied both to the goods rescued and to the money paid for their rescue from damage or loss, especially at sea.

SCALPER.— A speculator who aims for quick, small profits.

SCRIP.— A provisional certificate, or receipt for money paid for fractional parts of shares or as instalments for shares to be exchanged for a more formal certificate when conditions agreed upon have been complied with. The possession of scrip does not carry voting privileges. Scrip is sometimes issued as a dividend on stock.

SECURED CREDITOR.— A creditor whose claim is protected by a lien.

SECURITIES.— Documents given as an evidence of debt.

SELLER FOUR (or Ten, Twenty, Thirty or Sixty).— The right of the seller to deliver stock (on one day's notice) within the time specified. See BUYER FOUR

SET-OFF.— The balancing of one debt by another.

SHARE.— The unit, or one of the entire number of equal parts into which the capital stock of a company or corporation has been divided.

SHAVING.— As applied to a note, buying it at a sum less than its value at regular legal interest or discount.

SHOESTRING.— A term applied to a small beginning of a speculation which results in large profits.

SHORT.— Owing stocks sold but not yet in hand. Such selling is done on the expectation that the price of such stocks will fall and that then they can be bought for delivery for less than they were sold for.

SIGHT PAPER.— Bills of exchange, notes, etc., which are payable upon presentation.

SILENT PARTNER.— A person who maintains an interest in a business enterprise but who takes no active part in its management.

SINKING FUND.— A fund constituted for a special purpose; usually for the amortization of a debt, as the redemption of bonds.

SMART MONEY.— Money paid for the privilege of being released from fulfilling a contract.

SPREAD.— A double speculation covering the option of a delivery of a designated stock at one price, or its purchase at another price. The speculator pays a sum of money for the option. See BACK SPREAD.

STOCK.— (*a*) The accumulation of merchandise in the possession of a merchant; (*b*) the share capital of a corporation.

STRADDLE.— The double privilege of either buying or selling a stock at a fixed price. The profit or loss depends wholly on the changes of the market.

SUPERCARGO.— The person who has charge of a ship's cargo.

SUSPENSION OF PAYMENT.— The act of discontinuing the payment of debts because of insolvency.

TARE.— A deduction made from the gross weight of goods to allow for the weight of the box, or package containing them.

TENDER.— An offer, in writing, to perform some specific service or to supply certain articles at a specified rate and upon stipulated conditions.

TOLERANCE.— The limit of wear which a coin may sustain and still be worth its face value at the United States Treasury. For gold coins this limit is one-half of 1 per cent in 20 years use (from date): for a shorter period the tolerance is pro rata. On silver and lesser coins the tolerance is without limit.

TONTINE.— An annuity, in which the subscribers to the loan share under the benefit of survivorship, the share of each increasing as other subscribers die until the whole reverts to the last-living subscriber.

TRADE MARK.— The special mark or brand used by a commercial firm to distinguish goods of their individual trade. Such a mark becomes the property of the firm, and is protected as such by the courts. It need not be registered at the Patent Office.

TRET.— A now almost obsolete custom of making an allowance to purchasers who were compelled to transport their own goods.

TRUCK SYSTEM.— The system of paying employees partly or wholly in goods instead of money.

ULLAGE.— The estimated measure of the empty portion of a cask.

UNBALANCED BID.— A bid for the performance of work in which the rates specified for each of the various kinds of labor or material required have been based upon an erroneous estimate of the quantities of each, thus making a high bid appear as a low estimate.

UNEARNED INCREMENT.— The increase in the value of land resulting from such general causes as the increase of population, etc., as distinguished from the increase due to the efforts of its individual owner.

UPSET PRICE.— The lowest figure at which bids for property will be accepted at auction sales or other competitive buying.

USANCE.— The time allowed for the payment of bills of exchange drawn on foreign countries. The term is also used as another word for interest.

VOUCHER.— A written document in proof of money transactions.

WASHING.— The practice of buying and selling the same stock by a combination of brokers for the sole purpose of recording the quotations, and making it appear active. See MANIPULATION.

WITH EXCHANGE.— As included in a draft, signifies that the cost of collection is to be paid by the payee of the draft.

COMMERCIAL TREATIES. Definition.

Treaties of commerce and navigation are agreements between nations relative to the privileges and immunities which may be enjoyed by the commerce and by the citizens or subjects of each party to the treaty within the territory of the other. In general or specifically such treaties, conventions or agreements define the terms under which the citizens or subjects of each of the contracting governments may reside and pursue their industries and occupations within the territories of the other government, and under which the vessels and commerce of each may enter the ports, etc., of the other for trade and transportation. The object of such treaties is to procure the greatest possible freedom from discrimination in the pursuit of trade and the expansion of industries, and to this end they are reciprocal in terms.

In Case of War.— Permanent rights and general arrangements made between countries by treaty do not cease on the occurrence of war, but are, at the most, only suspended while the war lasts. (U. S. Supreme Court 1823—8 Wheat. 464, 494 — Moore, Vol. V).

Modern Policy.— A policy of discrimination in favor of one foreign nation as against others is repugnant to the modern spirit of commerce. The application of the principle that a favor granted by one nation to another must be equally extended to all other nations for like consideration is now almost universal. Usually nations entering into a treaty of commerce and navigation agree, reciprocally, to extend to the citizens or subjects and to the commerce of the other within its territories the same privileges that are enjoyed by natives, under the laws of the nation within whose territories such privileges are granted.

Great Britain, France and Germany.— Great Britain, France and Germany has each a distinct policy as to concessions for trade expansion, each applying a form of discrimination in its own favor without violation of the principle of equality of treatment of foreign nations. Great Britain, as a free trade nation, opposes the employment of discriminating customs duties and places the broadest possible construction upon the «most favored nation» principle. The policy of France has been that of specific reservations favorable to her own citizens, but is tending toward greater liberality. In 1882 she terminated all her European tariff treaties, and in 1892 adopted a minimum tariff for all nations with whom she had a most favored nation agreement and a maximum tariff for all others. The Entente Cordiale convention between France and Great Britain (1904) made provision for equality of import, customs dues,

etc., as to trade, commerce and navigation facilities of each with Morocco and Egypt; with reference to the Suez Canal and Gibraltar and as to fisheries in certain portions of the territorial waters of Newfoundland. In 1907 a reciprocal treaty was entered into between the two governments as to Canada, dealing with specific schedules, later (1909) enlarged in scope.

Germany in 1902 adopted a tariff system which was put into effect in 1906, making an increase in tariff rates, but providing lesser or «conventional» rates to be made effective by commercial treaties. The most favored nation clause in existing treaties of the empire was terminated and in 1905 treaties were made with Austria-Hungary, Russia, Italy, Switzerland, Belgium, Rumania and Serbia, by which these countries get the benefit of the «conventional» rates.

United States.— In the enactment of the 1909 tariff the United States adopted the maximum and minimum system effecting commercial agreements, but preserved the most favored nation principle as interpreted by this government. A concession of the lower rates was accorded to countries not unduly discriminating against the United States, and all countries now enjoy this concession.

Most Favored Nation.— The most favored nation clause, contained in nearly all treaties, may be declared in a few words with respect to each provision of a treaty, or be made the subject of a separate article. The form approved by the United States is: «Except as otherwise expressly provided in this treaty, the High Contracting Parties agree that, in all that concerns commerce and navigation, any privilege, favor or immunity which either contracting party has actually granted, or may hereafter grant, to the citizens or subjects of any other State shall be extended to the citizens or subjects of the other contracting party *gratuitously if the concession in favor of that other State shall have been gratuitous, and on the same or equivalent conditions, if the concession shall have been conditional.*»

The United States construes the most favored nation clause to imply a reservation as to favors granted gratuitously, whether so stated in exact terms or not. (Adams, 1817; and adhered to by U.S. State Department.)

United States and Japan.—In 1911 these countries entered into a treaty which superseded that of 1894. The treaty of 1911, outlined below, remained in force until, as a direct result of her war with China, Japan was notified, 26 July 1939, that the United States would not be bound by the treaty after 26 Jan. 1940. It provided:

«The citizens or subjects of each of the High Contracting Parties shall have liberty to enter, travel and reside in the territories of the other, to carry on trade, wholesale or retail, to own or lease and occupy houses, manufactures, warehouses and shops, to employ agents of their own choice, to lease land for residential and commercial purposes, and generally to do anything incident to or necessary for trade upon the same terms as native citizens or subjects, submitting themselves to the laws and regulations there established.

«They shall not be compelled, under any pretext whatever, to pay any charges or taxes other or higher than those that are or may be paid by native citizens or subjects.

«The citizens or subjects of each of the High Contracting Parties shall receive, in the territories of the other, the most constant protection and security for their persons and property, and shall enjoy in this respect the same rights and privileges as are or may be granted to native citizens or subjects, on their submitting themselves to the conditions imposed upon the native citizens or subjects.

«They shall, however, be exempt in the territories of the other from compulsory military service, either on land or sea, in the regular forces or the national guard, or in the militia; from all contributions imposed in lieu of personal service, and from all forced loans or military exactions or conditions.»

Other articles of the treaty provide that the dwellings, manufactures and shops of the citizens or subjects of one country in the territories of the other, and all premises appertaining thereto shall be respected . . . That there shall be no domiciliary search of premises nor examination of books, papers or accounts, except under conditions prescribed by law for the natives . . . Provide for the appointment of consular officers, with all the authority and immunity accorded those of any nation, in all ports, cities or places opened to commerce to any nation. . . . That there shall be freedom of commerce, reciprocally between the two countries, the citizens of each, equally with those of the most favored nation, having liberty to come with their ships and cargoes to all places, ports and rivers opened to foreign commerce, subject to the laws of the country into which they come. . . . That the import on articles imported shall be regulated by treaty or internal legislation . . . That no export duties or charges shall be made nor prohibition of export or import imposed, except such as apply to all foreign nations, this not to apply, however, to prohibitions imposed as sanitary measures or to protect animals and useful plants. . . . Reciprocal enjoyment upon equal terms is accorded to the people of both countries in the territories of the other, in exemptions from transit dues and privileges relative to warehousing, bounties, facilities and drawbacks.

Limited liability and other companies and associations, commercial, industrial and financial, already or hereafter to be organized in accordance with the laws of either country and domiciled in the territories of such country, are authorized, in the territories of the other country, to exercise their rights and appear in the courts either as plaintiffs or defendants, subject to the laws of such other country. This stipulation has no bearing upon the question of whether a company or association organized in one of the two countries will or will not be permitted to transact its business or industry in the other, this permission remaining always subject to the laws and regulations enacted or established in the respective countries or in any part thereof.

No discrimination is permitted by either country against the vessels of the other in the matter of import charges, reciprocal equality of treatment being accorded whether articles of import come directly from the place of origin or from any other foreign place. No

discrimination of any sort as to either import or export is permitted. No duties of tonnage, harbor, pilotage, quarantine or other similar or corresponding duties, are to be levied except as applied to vessels of the most favored nation. Coasting trade is to be regulated by the laws of the respective countries, but each is to have the same treatment as that accorded the most favored nation. Rights as to trademarks, designs and patents are reciprocally the same as those accorded to natives; and the general declaration as to most favored nation is incorporated as a separate article of the treaty.

This treaty illustrated the general scope and purpose of such compacts between nations for reciprocal treatment of commerce and navigation. Local laws, habits and conditions require variations in form, and national policies determine how far such engagements may be extended to the colonies of a nation, or what ports may be closed to all foreign commerce.

Open Ports.— The United States, by an act of Congress approved 24 May 1828 opened all ports of this country to the vessels of all nations on the same terms as our own vessels in return for reciprocal treatment, without discrimination as to the nature of the merchandise carried or the ports where laden. In general, throughout the world, ports that are open to foreign commerce are open to all foreign nations on equal terms.

Retaliation and Embargo.—The application of the principle of retaliation and embargo has in recent years been generally recognized to be detrimental to expansion of commerce and unprofitable to the nation applying it. Any departure from the most favored nation principle reciprocally applied meets with disfavor among nations engaged in commerce. Attempts by various nations to apply such discriminations, for profit or in resentment, have not been beneficial to their own commerce.

Treaty Tariffs.— Reciprocal benefits from reductions in tariff dues are resorted to for the encouragement of better commercial relations between rival nations, but customarily the most favored nation principle is observed, at least in theory. Reciprocal tariff treaties with South and Central American republics by the United States under the provisions of the McKinley tariff act failed of ratification. Similar treaties made with leading foreign countries under a provision of the tariff act of 1897 were terminated on account of the constitutional objection to tariff regulations not approved by legislative enactment, and in the place of these the maximum and minimum system adopted by the tariff act of 1909 was applied to our commercial relations. This act provided that the minimum rates (a reduction of 25 per cent) might be collected from countries which do not unduly discriminate against the United States, the higher rates to apply to all others. President Taft proclaimed the lower rates to all countries, after the adjustment of some differences with Germany and France (1910). France and Germany also have the maximum and minimum system, under which (in their practice) discriminations occur.

The Open Door.— At the instance of the United States in 1899–1905, agreements were entered into between the United States and France, Germany, Great Britain, Italy, Japan and Russia, extending the enjoyment of perfect equality of treatment for their commerce and navigation within the «spheres of influence» over which any should exercise control in China, the most favored nation provision being the ruling principle.

The treaty between Great Britain and Japan (1905) provided for «The preservation of the common interests of all Powers in China, by insuring the independence and integrity of the Chinese Empire and the principle of equal opportunity for the commerce and industry of all nations in China.» It also recognized the paramount right of Japan to take measures of guidance and control over Korea, «providing always that such measures are not contrary to the principle of equal opportunity for the commerce and industries of all nations.»

Special Features of United States Treaties. — By notice of the United States, the «most favored nation» clause in the (1850) treaty with Switzerland was «arrested» in 1899, together with some other articles, the general features of the treaty remaining in force.

The *Argentine* treaty (1853) provides that in case of war between the two countries, the citizens of either of them residing in the territory of the other shall have the privilege of remaining and continuing their trade or occupation therein without any manner of interruption so long as they behave peaceably and commit no offense against the law; and their effects and property, whether entrusted to individuals or to the state, shall not be liable to seizure or sequestration, or any other demands than those which may be made upon the like effects or property belonging to the native inhabitants of the state in which such citizens may reside. Provision is made also for religious liberty and the right of burial in grounds owned by aliens.

The *Belgian* treaty (1875) reserves the right on the part of Belgium to grant special importation privileges to products of her national fisheries, and provides for the termination of the most favored nation clause by either party by one year's notice, without affecting the other provisions of the treaty.

The *Bolivian* treaty (1858, proclaimed 1863) makes reservation of waterways artificially rendered navigable, while opening freely all others under terms of the favored nation provision. This treaty also grants, reciprocally, the right of refuge or asylum to vessels of either country, «whether merchant or of war,» from «stress of weather, pursuit of pirates or of enemies . . . giving them all favor and protection for repairing their ships and placing themselves in a situation to continue their voyage without obstacle or hindrance of any kind.» All the provisions of this article apply to privateers or private vessels of war as well as to public until the two countries relinquish this right in consideration of the general relinquishment of the right of capture of private property upon the high seas.

Free Ships and Free Goods.— In the Bolivian treaty and other treaties of about that period, some of which, like that of Bolivia, are still in force, the following broad principle of international law is made: «The two High Contracting Parties recognize as permanent and immutable the following principle, to wit: (1) That free ships make free goods, that is

to say, that the effects or goods belonging to the subjects or citizens of a Power or State at war are free from capture or confiscation when found on board a neutral vessel, with the exception of articles contraband of war. (2) That the property of neutrals on board an enemy's vessel is not subject to confiscation unless the same be contraband of war. The like neutrality shall be extended to persons who are on board a neutral ship with this effect, that although they may be enemies to both or either party, they are not to be taken out of that ship unless they are officers or soldiers, and in the actual service of the enemies. The contracting parties engage to apply these principles to the commerce and navigation of all such Powers and States as shall consent to adopt them as permanent and immutable.»

The treaty enumerates articles which shall be regarded as contraband of war, limiting these to arms, munitions, uniforms, horses and actual military equipment, and extending liberty of navigation to all merchandise other than the character of articles enumerated.

In case of war between the two countries, the merchants of either doing business within the territory of the other must depart within six months if on the coast or within one year if in the interior. All of other occupation may remain.

The *Brazilian* treaty (1828), of similar character, was abrogated in 1841, except as to the most favored nation clause and general provisions for freedom of commerce and navigation. The agreement effected in 1923 accords mutual unconditional most-favored-nation treatment in custom matters.

The *Chilian* treaty (1832), similar to that with Bolivia, was abrogated in 1850.

The *Chinese* treaty of 1903 re-enacted provisions of treaties then in force except in so far as they were modified by other treaties to which the United States was a party. The broadest most-favored-nation clause was provided by this treaty. A new treaty regulating tariff relations was proclaimed in 1929.

The *Colombian* treaty (1846) contains the «Free ships make free goods» article of the Bolivian treaty, to which it is similar.

The *Cuban* relations (1902) are exceptional, articles from the Island being admitted to the United States at a reduction of 20 per cent and articles to Cuba at a reduction of from 20 to 40 per cent.

With *Czechoslovakia* there is a mutual unconditional most-favored-nation treatment in customs matters by the agreement of 1923.

The treaty with *Denmark* omits the most-favored-nation clause.

The *Dominican* treaty was abrogated in 1898. Unconditional most-favored-nation treatment is embodied in the new agreement which was signed in 1924, also in that with *Haiti* (1926).

The *Ecuadorian* treaty (1839) was terminated in 1892.

In 1930 unconditional most-favored-nation treatment was agreed to with *Egypt*. A treaty of commerce, signed with *Ethiopa* in 1914, was proclaimed in 1920.

Estonia, Latvia, Lithuania, Poland and *Finland* are also among the most-favored-nation agreements; and the first two also are embraced in treaties of friendship, commerce and consular rights, made in 1926 and 1928 respectively.

The «temporary convention» entered into with *France* in 1822, for two years, or «until the conclusion of a definite treaty,» is still in force. But Article VII of this convention was modified in 1919 and proclaimed in 1921. A provisional arrangement in regard to customs matters was the subject of an agreement signed in 1927 and effective 21 Nov. 1927.

Germany renounced her reciprocity treaty with the United States in 1906—before all similar treaties were legislated out of existence by the United States Tariff Act of 1909. Treaties with all Germanic governments made prior to the formation of the German Empire in 1871, not conflicting with the Prussian treaty, were assumed by the empire. The United States did not stand in «most-favored-nation» relations with Germany so as to enjoy the minimum tariff rates of that country until partly obtained by the arrangement of 1910. But in December 1923 a treaty of commerce, amity and consular rights, containing most-favored-nation treatment articles, was signed.

The treaty with *Great Britain* made in 1815 was indefinitely extended in 1827. It applied the favored-nation clause to British East Indies as well as to England, but prohibits commerce by American vessels with India and Cape of Good Hope. Reciprocal relations between the United States and Canada, based upon an accommodation of customs dues and the free entry of a specified list of articles into each country, were established by a treaty approved by legislative action by the United States Congress in 1891.

By the agreement signed in 1924 *Greece* is included among those having the unconditional most-favored-nation clause; also *Rumania* by treaty of 1930.

With *Guatemala* and *Nicaragua* the treaties of 1924 contain the provision for unconditional most-favored-nation treatment. There are treaties of friendship, commerce and consular rights, with *Honduras and Salvador,* made in 1928 and 1930, respectively.

A treaty of friendship, commerce and consular rights was signed with *Hungary* in 1925.

The *Italian* treaty (1871) contains the «Free ships make free goods» declaration and agrees «that a state of war between one of them and a third Power shall not, except in the case of blockade and contraband of war, affect neutral commerce of the other,» defining an effective blockade in terms, so that there shall be no misunderstanding.

The *Mexican* commercial reciprocity treaty of 1884 lapsed in 1887, because of a failure on the part of the United States Congress to enact tariff legislation essential to its operation.

The *Netherlands* treaty (1852) regards trade between the East Indies of the Netherlands as coast trade and reserves the right to discriminate in import and export duties in favor of direct trade between Holland and her colonies, but grants to American vessels the same privileges as those under the Dutch flag.

The *Russian* convention (1832) was terminated by a resolution of the United States Congress in 1911 because «no longer responsive in various respects to the political principles and commercial needs of the two countries»; and because «the construction placed by the respective contracting parties differ upon matters of fundamental importance and interest to each.»

A commercial agreement was effected with *Spain* by royal decree in 1927 and, in the same year, extended indefinitely.

A provisional agreement was made with *Persia* in 1928.

In 1929 a treaty of commerce and navigation was signed with *Turkey*.

Albania accords most-favored-nation treatment to American interests by agreement signed in 1922 and approved by the Albanian parliament in 1925.

A treaty and protocol revising hitherto existing treaties was signed with *Siam* in 1920.

There have also been made treaties with *Belgium, France, Great Britain* and *Japan* relating to rights in former German and Turkish possessions, which are now mandated territories.

Since 1934 the United States has concluded a series of reciprocal trade agreements with various foreign countries. See TRADE TREATIES PROGRAM, UNITED STATES.

JOHN PIERCE MILLER.

COMMERCY, kō'mär'sē', France, town in northeast France, in the department of the Meuse, on the left bank of the Meuse River, about 180 miles east of Paris. In its ancient castle the Cardinal de Retz wrote his memoirs. The town is tolerably well built, and its industries include ironworking, boot and nail making, hosiery, embroidery, tanning and brewing. The cavalry barrack was once the residence of King Stanislas of Poland. Pop. 7,300.

COMMERSON, kō-mär-sŏn, **Philibert,** French botanist: b. Chatillon-les-Dombes, 18 Nov. 1727; d. Mauritius 1773. At the request of Linnæus he composed a treatise on the 'Fishes of the Mediterranean,' the most important ichthyological work that has yet appeared. In 1767, at the command of the king of France, he accompanied Bougainville on his voyage round the world. He died on the Isle de France (Mauritius), after residing there for about four years, which he spent in gathering and correlating and studying a vast amount of material which helped greatly the study of biology. He wrote, among other things, a botanical martyrology — a biography of those who have fallen victims to their efforts in the cause of botany. He left his plants, drawings and papers to the royal cabinet at Paris. Commersonia, a genus of the family *Sterculiaceæ,* was named in his honor.

COMMINATION, an office in the liturgy of the Church of England, appointed to be read on Ash Wednesday (the first day of Lent), containing a recital of God's anger and threatenings toward sinners.

COMMINES, kō-mēns, or **COMINES,** France and Belgium, towns on opposite sides of the Lys, eight miles north of Lille. The one on the right bank is in the department of the Nord, France, and communicates by a drawbridge with the other, which is in the province of West Flanders, Belgium. Anciently they formed a single town, which was fortified and had a castle, in which the celebrated historian, Philippe de Commines, was born. The manufactures are chiefly ribbons and cotton goods, tanning and cutlery. Pop. of French Commines, 6,400; of Belgian Commines, 6,641.

COMMISSARIAT, kŏm-mĭs-sār'ĭ-at, that department of an army which provides provisions, forage, camp equipage and all the daily necessaries, other than those connected with actual fighting. Up till 1912 the provisioning of the United States army was in the care of the Department of Subsistence; but in that year this department was united with the quartermaster's and pay departments into one of supply under the title of the Quartermaster's Corps, and charged with the provision of subsistence, pay, transportation, clothing and quarters. In the British army the duties of the commissariat have been managed by different bodies at different times, and at present there is no department so named. The commissariat duties now partly fall on the Army Service Corps, while there is also an ordnance store department for the supply of war provisions. It is only in the latter body that there are officers designated commissaries.

COMMISSARY (L. *commissus,* pp. of *committere,* commit, Fr. *commissaire,* one entrusted with a task, duty or office). In a general sense a commissary is, as its root meaning signifies, one to whom some charge, duty or office is committed by a superior power; hence one who is sent, with delegated power, to execute some official duty in a certain place. Here it has the sense of commissioner. An officer of a bishop who exercises spiritual jurisdiction in remote parts of a diocese, or one entrusted with the performance of duties in the bishop's absence. In *Scotts law* a commissary is a judge in a Commissary Court (q.v.). For this term in its military sense, see COMMISSARIAT.

COMMISSARY COURT, in *Scotts law,* was a Supreme or High Court established in Edinburgh in the 16th century which took to itself the duties formerly incumbent upon and performed by the bishops' commissaries. It had jurisdiction over actions for divorce, declarator of marriage and nullity of the same and all matters related thereto. This court, which was abolished in 1836, is embodied in the powers of the Court of Sessions. A second meaning of this term is that of a Sheriff's Court or County Court having the power to decree and confirm executors to deceased persons leaving property in Scotland. See COMMISSARY.

COMMISSION. (1) Formal act of trust; a warrant by which any trust is held or authority exercised. (2) A written document investing a person with an office or certain authority. (3) A certificate issued by authority by which a military officer is constituted; as, a captain's commission. (4) A body of persons joined in an office or trust, or their appointment; as, a building commission. (5) Brokerage, allowance or compensation made to a factor, agent, etc., for transacting the business of another; as one per cent commission on sales. (6) A warship is said to be "in commission" when she is fitted out for service and her commanding officer has taken charge under his commission (see definition (3), above). (7) In an official sense, a commission is a legally created body of persons invested with limited but well-defined jurisdiction, as the Interstate Commerce Commission, the Civil Service Commission, the Anthracite Coal Commission, etc.

Commission of Bankruptcy. — A commission appointed to investigate the facts relative to an alleged bankruptcy and to secure all

available assets and effects for the creditors concerned.

COMMISSION, Governmental. A more or less temporary board to which authority is delegated for a specific purpose. Commissions may be used either for domestic government or for international arbitration. Among the more important commissions which have been employed in the United States for the settlement of internal problems are the Interstate Commerce Commission and the Industrial Relations Commission (qq.v.). In Great Britain a recognized means of collecting information for the purposes of determining a policy or formulating legislation is the employment of commissions of inquiry. These are classed as royal, statutory or departmental, according to whether they are appointed by a command of the Crown, by an act of Parliament or by a treasury minute or the authority of a Secretary of State. The authority of these commissions is dependent on the particular terms of their creation.

The United States has often made use of commissions to adjust the claims of individual citizens with reference to international disputes. Commissions of this sort were employed in connection with the Treaty of 1819 with Spain, in which Florida was ceded; under the Treaty of 1826 with Great Britain, to distribute the indemnity granted for slaves deported in violation of the Treaty of Ghent; under the Treaty of 1831 with France, to distribute the indemnity for the Spoliation Claims; and under the Treaty of 1871 with Great Britain, to distribute the indemnity for the Alabama Claims.

Arbitrations are usually carried on by international commissions, which may or may not contain, in addition to the representatives of the nations involved in the dispute, the representatives of disinterested neutral nations. The commission may have authority sufficiently wide to settle the entire question at issue, or it may recommend courses to the governments concerned, without imparting to these recommendations any binding force. See ARBITRATION; BERING SEA CONTROVERSY; BOUNDARIES OF THE UNITED STATES; and the accounts of the various boundary and fisheries disputes between England and America which were likewise settled by commissions.

COMMISSION, Military, a certificate which entitles one to execute the more important functions of command or staff duty in an army or navy. They are granted by the head of the government, and in the United States are confirmed by the Senate and are made public through the adjutant-general's department. In the national guards of the several States they are granted by the governor. In general, commissions are granted after courses of training such as those discussed under the heads of MILITARY ACADEMY, UNITED STATES; MILITARY EDUCATION; NAVAL ACADEMY, UNITED STATES. These are generally supplemented by systems of examination whereby qualified non-commissioned officers or warrant officers may acquire commissions. In most European armies certain social or financial qualifications are required for commissions. Up to 1871, when Gladstone abolished it notwithstanding vigorous opposition, a system of purchase of commissions existed in Great Britain, except in such technical arms as the engineers and artillery and in a few other organizations. This system, initiated in the time of Charles II, continually became more expensive, until in 1854, during the Crimean War, the prices ranged from £450 for the commission of an ensign in the line to £7,250 for the commission of a lieutenant-colonel of footguards. Under the present system in times of peace, besides the regular course of training as cadet and the examinations given to highly recommended non-commissioned officers, the avenues of approach to commissions in the British army are the officers training corps of the universities, the special reserve of officers and the territorial force. In the United States army, besides West Point and promotion from the ranks, commissions may be obtained on examination and appointment from civil life, by specially recommended men from various training corps at educational institutions where army officers are stationed, and in the Officers Reserve Corps, by the methods explained in the article on that corps. In the European War, special training courses for aspirants to commissions were initiated at Plattsburg and elsewhere. Of course, in all armies, the bars to commissions — which are then usually temporary — are greatly let down in times of war, and it is possible for a qualified enlisted man or civilian to get a commission without going through the course of training or the highly technical examinations necessary in times of peace. See RANK.

COMMISSION FORM OF GOVERNMENT. Definition and Origin.— The commission form of government is that system of city administration in which all legislative and executive powers are vested in a single body of five elective commissioners or councilmen. The plan originated in Galveston, Tex., in 1901. Prior to that time all American cities were governed by a mayor and various administrative boards exercising the executive functions of government and by a city council of one or two chambers exercising the legislative power. The Galveston experiment accordingly marked a departure from the traditional principle of division of powers in American municipal affairs. Its adoption in Galveston was intended as a temporary measure to carry the city through the grave financial emergency caused by a tidal inundation which had destroyed a great deal of private and municipal property in September 1900. But the commission plan proved successful in its workings and soon attracted the attention of other communities.

Outline of the Galveston Plan.— As originally framed, the commission plan in Galveston provided that all powers formerly vested in the mayor, the various administrative boards and the city council should be vested in a body of five citizens of whom three were to be appointed by the governor of Texas and two elected at large by the voters of Galveston. The provision for the appointment of three commissioners by the governor was decided by the courts to be unconstitutional, however, and the scheme was amended to provide for the election of all five commissioners. At the ensuing election the voters endorsed the commissioners who had been already appointed by the governor. Under the terms of the charter of 1901, as thus amended in 1903, the members of the commission were to serve for a two-

year term and one of the commissioners was given the title of mayor-president but with no special functions save that of acting as chairman at meetings of the commission. It was provided that the commission should hold regular sessions, open to the public, and that by a majority vote of its members it should enact municipal ordinances, make the appropriations, award all contracts for public work and determine all appointments to positions in the city's service. It was further provided that the commissioners should, by majority vote, apportion among themselves the headships of the four main departments of civic administration, namely, finance and revenue, waterworks and sewerage, police and fire protection, and streets and public property. The mayor-president was not to be assigned to the headship of any department but to exert a co-ordinating influence upon them all. These were the essentials of the Galveston Plan.

Extension to Other Texan Cities.— Although it had been prepared hastily, with little or no experience elsewhere to serve as a guide, the Galveston experiment soon demonstrated its success. When the commissioners took over their duties the city had already defaulted in the payment of interest upon its debt; its bonds were selling at 40 per cent below parity and it had a large floating debt which could not be funded. Within a few years, however, this situation had been enormously improved. The city was once again able to pay its way in spite of the great burdens due to the cost of reconstructing the inundated sections. Accordingly, what had been designed as a makeshift to tide over a serious emergency not only became a permanent scheme of government for Galveston but was within a few years adopted by the other cities of Texas.

The Des Moines Plan.— In due course this Galveston system found its advocates in other States of the Union. Its progress was slow, however, because of the feeling that the plan concentrated too much power in the hands of a small group of men. While retaining its main principles, therefore, some cities sought to improve its practical applications. Most important among these was Des Moines, Iowa, which in 1907 adopted a new charter providing for a commission of five men nominated at a non-partisan, open primary and elected at large with additional provision for the use of the initiative and referendum by the voters of the city as well as (see INITIATIVE AND REFERENDUM) for the recall of one or more of the commissioners at any time after three months' tenure of office (see RECALL). The Des Moines plan further provided that no franchise giving rights in the city's streets should be valid until confirmed by popular vote. In general it aimed to establish what the Galveston plan did not seem to provide, namely, some adequate safeguards against the abuse of the large powers entrusted to the five commissioners.

Spread of the System.— With the new safeguards which the Des Moines plan added to the original scheme, the commission plan of city government gained great popularity. During the next few years it found adoption, without any change except as regards minor details, by many American cities, large and small, in nearly all the States of the Union. At the present time more than 300 municipalities of all sizes are governed by commissions. The majority of these are small communities with populations not exceeding 10,000; but some of the largest cities of the United States, notably Newark, New Orleans, Jersey City, Portland, Saint Paul, Oakland, Houston, Dallas, Birmingham, San Antonio, Memphis and Omaha are included in the list. Among commission governed cities there are now 24 with populations exceeding 100,000. Of the larger municipalities which once adopted the plan only two, Denver, Colo., and Buffalo, N. Y., have abandoned it.

The Commission-Manager Plan.— A further development of the original plan soon took place in the adoption by many cities of an arrangement which, while retaining the commission, established a new administrative post known as that of city manager. Under this plan the commission retains all its legislative and policy-determining powers but devolves responsibility for the actual administrative work upon a highly-paid, professional official who makes the subordinate appointments and is accountable for securing efficiency in the various departments. This variation of the original scheme is now used by 60 or more cities in addition to many others which have established the city manager plan in conjunction with a larger city council instead of a small commission. See CITY MANAGER.

Merits of the Commission Plan.— The chief advantages of the commission form of government are first of all the concentration of power in definite hands thus avoiding the delays, friction and evasion of responsibility which characterized the old system of government by a mayor, various boards and a double-chambered council. In the second place, by reducing the number of elective offices it has raised the plane of officeholding, securing for the commission citizens of a better type than those ordinarily elected to municipal positions. It has not wholly succeeded in ousting the professional office-seeker, but it has given the man of business ability a better opportunity to serve the city in an official capacity. In the third place, the commission plan has made possible the introduction of many notable improvements in the routine conduct of the city's business, as for example, improved methods of budget-making and accounting, the extension of the civil service system, publicity in the award of contracts, the development of new sources of city revenue, and the adoption of a pay-as-you-go policy in municipal finance. It has faciliated the introduction, in many cities, of the so-termed newer agencies of democracy such as the initiative and referendum, the recall, preferential voting, proportional representation, the short ballot and the open primary. Finally, it has had an educative value, awakening the interest of the citizens in their public affairs, making the government of the city simple and intelligible which is the first necessary step in making it responsible to them. More has been claimed for the plan, however, than it or any system of local government could of itself be expected to accomplish, but its substantial achievements are beyond question.

The Defects of Commission Government. — The chief objections to the commission form of city government, on the other hand, are that it may place a dangerously large amount of power in the hands of a few men and enable

them, by collusion, to carry corruption or dishonesty a long way without detection. It is furthermore urged that the plan violates a cardinal principle of American government by vesting both the appropriating and the spending powers in the same hands, something that is not permitted in national or State government. There the tradition of checks and balances is still powerful. It is contended, however, that a legislative body ought to be fairly representative of all interests in the community and that a body whose membership is limited to five men cannot be adequately representative. Finally, there is the allegation which experience seems to support, that it divides among five men the responsibility which was formerly concentrated in one man, the mayor. In other words, the plan goes too far in one direction and not far enough in another. The commission is too small to be adequately representative as a legislative body and too large to be efficient as an administrative organ. The adoption of the city manager plan, with provision for a city council, is a recognition of this defect in the commission form of government.

Financial Results.—The financial results of the commission plan have been shown to be good as the result of a careful investigation made in 1916 by the United States Bureau of the Census. Comparing cities which have remained under the mayor and council framework with those which have had some years of experience with commission government the balance of advantage appears to rest with the latter in such matters as lowered tax rates, more efficient checks upon expenditure, better budget methods and a reduction on municipal debts. See MUNICIPAL GOVERNMENT; CITY MANAGER.

D., 'City Manager' (1927).

WILLIAM BENNETT MUNRO,
Professor of History and Government, California Institute of Technology.

COMMISSION MANAGER, the chief administrative officer under the commission plan of municipal government. He is responsible for the efficient administration of all departments. See CITY MANAGER.

COMMISSIONAIRE, kŏm-mĭs-syô-nār', the attendant attached to European hotels, who awaits the arrival of the trains to secure customers, to look after their luggage, etc. He may also be employed as guide or otherwise. In London, Edinburgh and elsewhere bodies of commissionaires have been established, the men being drawn from the ranks of military pensioners of undoubted character. In a secondary sense a commissionaire is in general a kind of light porter or messenger.

COMMISSIONER, a member of a commission. See COMMISSION.

COMMISSURE, an anatomical term applied to nervous connections between adjacent parts of the nervous system. Though it is not always used in quite the same way, the general signification of the term, and the physiological import of the structure, is that of a uniting bridge. It has the sense of a suture, seam, joint or closure, the places where two bodies or parts of a body meet or unite. In architecture the commissure is the joint between two stones formed by the application of the one to the other; in botany it signifies the face by which one carpel coheres to another; in anatomy it is the name for certain bands of nerve-tissue which connect the right and left parts of the brain with the spinal cord; while in zoology it is a nerve cord connecting the larger ganglia of the nerve system.

COMMITMENT, *in law,* a written warrant for the arrest of a person named or described therein; also, the placing of a person in jail, as by warrant, for crime, contempt or the like. The word is applied usually when the detention is for a short period, so as to secure bail or to hold for trial. A commitment is made only after the person to be committed has made his appearance or has been summoned, in which particular it differs materially from a warrant. Commitments may be made by civil courts, although they are more commonly made by criminal courts.

COMMITTEE, one or more persons elected or deputed from among a larger body to examine, consider and report on any matter of business.

Large deliberative assemblies, with a great variety of business coming before them from time to time, are unable, when sitting as a whole, sufficiently to discuss and investigate many subjects on which they are obliged to act. Committees, therefore, are appointed to examine and report to the assembly from which they are selected. In the legislative bodies of the United States and in the British Parliament — in fact, in all legislative bodies in representative governments — there are committees for various purposes. What are known as «standing committees» and «grand committees» are regularly appointed at the beginning of every session, and have a definite class of subjects with which to deal, the object being to divide the work of the assembly among several bodies, and so facilitate the progress of legislation. In the British Parliament there were formerly four grand committees — of Religion, of Grievances, of Courts of Justice and of Trade, but they fell into disuse and were discontinued in 1832. Another ancient committee is that of Privileges, which is still appointed at the beginning of every session, but has seldom any work to do, questions of privilege being generally laid before a select committee specially appointed. In the United States Congress there are numerous standing committees. Among the most important of them in both Senate and House (though each House has not the same committees) are those on Appropriations, Commerce, Elections, Foreign Affairs, Judiciary, Military and Naval Affairs, Rules and Ways and Means. (See CONGRESS, UNITED STATES). «Select committees» are appointed by both Houses of the British Parliament and of the United States Congress to take

up special questions and investigate them previous to legislation. In these witnesses may be examined upon oath, and evidence of all kinds brought forward, the proceedings being such as could not be carried on before the whole House.

COMMITTEE FOR INDUSTRIAL ORGANIZATION (C.I.O.), labor group formed by officials of eight international unions affiliated with the American Federation of Labor in 1935 under the chairmanship of John L. Lewis of the United Mine Workers. Its purpose was to assist in the organization of mass-production industries on an industrial instead of a craft basis, that is to say, to organize all the employes of an industry into a single union irrespective of trade and craft. Industrial unions of this character had previously existed. The United Mine Workers, for instance, has always been an industrial union. But, in general, the craft had been the traditional basis of organization in the American labor movement, and the effort to organize the newer mass industries on a purely industrial basis led to conflict with many of the international unions in the American Federation of Labor. The Executive Council of the American Federation of Labor, by majority vote, suspended the ten organizations which held membership, as unions, in the C.I.O. This suspension was supported by the general American Federation of Labor convention in November 1936, the suspended unions not being represented at the convention. The original international unions that joined the C.I.O were: Amalgamated Association of Iron, Steel, and Tin Workers; Amalgamated Clothing Workers; Federation of Flat Glass Workers; International Ladies' Garment Workers' Union; International Union of Mine, Mill, and Smelter Workers; International Association of Oil Field, Gas Well, and Refinery Workers; International Union United Automobile Workers; United Mine Workers; United Rubber Workers; and United Textile Workers. In 1936 the C.I.O. proceeded with its organization campaigns in several industries. Primary attention was given to the iron and steel industry, but in 1937 the C.I.O. failed in its campaign in this industry. It met with greater success in the automobile industry, being able after some preliminary strikes and strife to organize this industry. Late in 1937 delegates from the American Federation of Labor and the C.I.O. met in an effort to compose their differences. These conversations proving futile President Green of the Federation of Labor and President Lewis of the C.I.O. met in December in a further attempt to heal the rift in labor's ranks. In November 1938, the C.I.O. was re-organized on a permanent basis as the Congress of Industrial Organizations (q.v.). See also under STRIKE AND LOCKOUTS—*Sit-Down Strikes.*

COMMITTEE OF PUBLIC SAFETY (*Comité du Salut Publique*), a body elected by the French Convention, 6 April 1793, from among its own members, at first having limited power conferred upon it—that of supervising the executive and of accelerating its actions. Later, its powers became extended; all the executive authority passed into its hands, and the ministers became merely its scribes. At first composed of nine, it was increased to 12 members—Robespierre, Danton, Couthon, Saint-Just, Prieur, Robert-Lindet, Hérault de Séchelles, Jean-Bon Saint-André, Barrère, Carnot, Collot d'Herbois and Billaud-Varennes. In the terms of its constitution the members should have been elected only for one month, but all the above-mentioned held their seats for a whole year. The prevailing party acted on the ground that France, threatened from within and without, could not be governed as if at peace, but could only be saved by desperate measures, as in times of the greatest danger. But after the downfall of the Girondists, 1 and 2 June 1793, when the Mountain, on the recommendation of the Committee of Safety, declared that the population of France consisted of but two parties—patriots and enemies of the Revolution—and consigned the latter to the persecution of all good citizens, terror took the place of law. As the sole rule of his conduct Robespierre declared that the mainspring of a popular government in a state of revolution was *la vertu et la terreur!* Carnot confined himself to the direction of the armies, and left to his colleagues the affairs of the interior. At the motion of these men the new constitution was suspended for a time, and the revolutionary government conferred on the Committee of Safety by a decree of the Convention of 4 Dec. 1793. The last remaining forms of regular process were abolished; their place was supplied by violence, and often by avarice and folly. Finally Danton, who had absented himself for a time from the committee, declared himself against the system of bloodshed; and Robespierre himself acquiesced in the condemnation of the ring-leaders of the Paris mob (24 March 1794), among whom was Hébert; but soon after (5 April) Danton, with Hérault de Séchelles, was himself overthrown by Robespierre. Till 28 July 1794 the latter now remained master of the lives of 30,000,000 of men. He appointed Fouquier-Tinville public accuser. Prisons were multiplied and crowded; the prisoners were cruelly treated, betrayed by spies and condemned without being allowed the privilege of defense; the property of all imprisoned on suspicion was confiscated, and the guillotine remained *en permanence.* The same violence was practised in the provinces by some of the delegates of the committee. Among the numberless victims of the system were the noble Malesherbes and the celebrated Lavoisier. The members of the Committee of Public Safety and of the *comité de sureté générale* at last disagreed among themselves. Each committee contained three parties. These, and not Tallien, were the real causes of the 9th Thermidor (27 July). In the Committee of Public Safety Robespierre, Couthon and Saint-Just (*gens de la haute main*) formed one party; Barrère, Billaud and Collot d'Herbois (*les gens revolutionnaires*) another, and Carnot, Prieur and Lindet (*les gens d'examen*) a third. In the *comité de sureté générale* one party comprised Vadier, Amor, Jagot, Louis (*du bas Rhin*) and Voulland (the *gens d'expédition*); to a second belonged Danton and Lebas (*écouteurs*); to the third Moïse Bayle, Lavicomterie, Elie Lacoste, Dubarran (*les gens de centrepoids*). Robespierre attempted to remove the unyielding Carnot from the Committee of Safety. On the other hand Billaud-Varennes labored to effect Robespierre's downfall. Couthon, Saint-Just, the Jacobins and the commune of Paris alone adhered to Robespierre. But when Saint-Just actually proposed in the committee a dictator-

ship for the safety of the state an opposition was raised against Robespierre in the National Convention by Vadier, Collot d'Herbois, Billaud-Varennes, and especially by Tallien and Fréron; the dictator and his faction were proscribed, and the victory of Barras (q.v.) on the 9th Thermidor brought Robespierre, his brother, Saint-Just, Couthon and others, 105 in all, to the scaffold, 28 July. The Convention now recovered its authority; the Jacobins and the partisans of terrorism (*le queue de Robespierre*) were completely overthrown; at the same time the Convention gave the Committee of Safety and the revolutionary tribunal a more limited power and jurisdiction. The bloody despotism ceased; and when a new constitution introduced (28 Oct. 1795) a directorial government (see DIRECTORY), the Convention was dissolved, and with it sank into its grave the revolutionary government, the reign of terror and the Committee of Public Safety.

COMMITTEES OF CORRESPONDENCE, in American Revolutionary history, public functionaries of a type first appearing in England, created by the parliamentary party of the 17th century in their struggles with the Stuarts. In 1763, when the English government attempted to enforce the trade and navigation acts in America after the Peace of Paris, the colonial leaders advised the merchants to hold meetings and appoint committees to memorialize the legislature and correspond with each other to forward a union of interests. This was done in Massachusetts, Rhode Island and New York 1763–64. On 13 June 1764 the Massachusetts General Court appointed a committee to communicate to other colonial governments its instructions to its agent in London, to protest against the Sugar Act and the proposed Stamp Act. When the latter was passed in 1765, the Sons of Liberty formed committees of correspondence to organize resistance. Samuel Adams, during the decade 1764–74, constantly urged the adoption of this plan by the patriots of every town and county in each colony, and moved the general court to that effect in 1770–71. A few public bodies in the country appointed such committees, but there was no general concert. The payment of judges' salaries by the royal government in 1772 was seized upon by Adams as a fresh incitement, at first with scant effect, but on 21 November a slender town meeting at Faneuil Hall, Boston, appointed a correspondence committee of 21 to communicate with other Massachusetts towns concerning infringements of popular rights. It consisted of the foremost popular leaders — Adams, Otis, Warren, Quincy, etc.— and until late in 1774 (see COMMITTEES OF SAFETY) remained the real executive of the town and largely of the province. A report of its first meeting was printed and sent to all the towns and to other provinces, and in a few weeks 80 Massachusetts towns had appointed similar committees, many more doing so in a short time. No fresh places in other colonies joined, though the report was printed in their newspapers. But the royal commission to investigate the burning of the *Gaspée* in Rhode Island and send the culprits to England for trial effected Adams' purpose — curiously, not in Rhode Island itself, but in Virginia, where the House of Burgesses, on 12 March 1773, appointed a committee of 11 to communicate with other colonies on the doings of the administration, especially in Rhode Island, and report. The plans were characteristically different, the Massachusetts being by the town voters, the Virginia by the legislature, but the latter was immediately effective in eliciting response. Committees were appointed by Rhode Island 7 May, Connecticut 21 May, New Hampshire 27 May, Massachusetts 28 May, South Carolina 8 July. This threat of united opposition daunted the government; the *Gaspée* prosecutions were not pressed, and the commission found adversely to its commander. There being nothing more to do, the legislative committees stopped for the time, after exchanging proceedings. The Boston committee alone continued its political activities, and the tea question (see BOSTON TEA PARTY) soon revived the others. The Boston committee, followed by that of Connecticut, sent out circulars urging the defeat of British purposes; and the former, by legal town-meeting, was made the executive of Boston. It called the committees of five surrounding towns into consultation, and sat «like a little Senate,» Hutchinson said. Under its direction the tea was thrown into the harbor. The Tea Act roused the remaining colonies: Georgia in September, Maryland and Delaware in October, North Carolina in December, New York and New Jersey in February, chose legistive committees of correspondence; and new municipalities joined the movement — several in New Hampshire and Rhode Island and the city of New York. After the Boston Port Bill came into effect the Boston committee invited those of eight other towns to meet in Faneuil Hall, and the meeting sent circulars to the other colonies recommending suspension of trade with Great Britain, while the legislative committee was directed by the House to send copies of the Port Bill to other colonies and call attention to it as an attempt to suppress American liberty. The organization of the committees was at once enormously extended; almost every town, city or county had one, though a few dismissed theirs in fear of the coming storm. The Boston opposition attempted this, but were crushingly defeated. In the middle and southern colonies the committees were empowered, by the terms of their appointment, to elect deputies to meet with those of other committees, to consult on measures for the public good. The history of the committees from this time on is the history of the preliminaries of the Revolution. Consult Frothingham, 'Rise of the Republic' (1872); Howard, 'Preliminaries of the Revolution' (1905).

COMMITTEES OF SAFETY, in American Revolutionary history, these were a later outcome of the committees of correspondence (q.v.). In Massachusetts, as affairs drew toward a crisis, it became usual for towns to appoint three committees, of correspondence, of inspection and of safety. The first was to keep the community informed of dangers either legislative or executive, and concert measures of public good; the second to watch for violations of non-importation agreements, or attempts of loyalists to evade them; the third to act as general executive while the legal authority was in abeyance. In February 1776 these were regularly legalized by the General Court; but consolidated into one, called the «Committee of Correspondence, Inspection and

Safety,» to be elected annually by the towns. This possessed all the powers of the other three, but in addition was empowered to notify the proper authorities of all violation of any of the acts, resolves or recommendations of the legislature; also to send for persons and papers, call out the militia, take charge of confiscated property and prisoners of war, and carry out the laws against Tories. An appeal lay from them to the legislature, but was not often thought judicious. Previous to this, however, in October 1774, the first Provisional Congress of Massachusetts had appointed a provincial committee of safety, with 11 members, to act as the general executive of the province; and in the next few weeks it made arrangements to raise and support an army. On 9 Feb. 1775 the second Provincial Congress constituted five members a permanent executive, and instructed it to «alarum, muster and cause to be assembled with the utmost expedition, and completely armed, accoutred, and supplied, such and so many of the militia of the province as they shall judge necessary,» such levy to be made when the committee thought a forcible attempt was to be made to carry out the Boston Port Bill. It was this committee's decision to take possession of Charlestown and Dorchester Heights, on the rumor that Gage was to have heavy reinforcements and occupy them, which led to the battle of Bunker Hill. New York had also a committee of safety, of 100 men, but it is characteristic of the undeveloped politics of the time that several of these were conservatives who afterward joined the British side. Partly from this, and partly from the unwieldy size of the committee, an inner committee was formed consisting entirely of Sons of Liberty, and directed its operations. At the news of the battle of Lexington, they called a public meeting in New York at the city hall, and secured the arms and ammunition in the arsenal. John Lamb and Isaac Sears led the action, arrested all British vessels about to sail for Boston, locked up the custom-house, and discharged the cargo of a vessel detained by British authorities as loaded with supplies for the patriots, formed a military company, armed it from the arsenal, surprised and captured the chief depot of British stores at Turtle Bay, and when the British commander ordered his men to join the army in Boston, refused to allow them to take any arms but those in their hands. Otherwise they were to be allowed to embark unmolested. The more ardent members were displeased at this, but kept the letter of the promise and no more. The muskets being carried in wagons, they confiscated them as not «in the hands,» the soldiers declaring that they should not be used against their brethren in Boston. Consult Sparks, 'Life of Gouverneur Morris' (Vol. 1, Chap. 2).

COMMODITY CREDIT CORPORATION. See UNITED STATES—*New Federal Agencies.*

COMMODORE, in the United States navy, formerly an officer ranking next above a captain, and commanding a few ships when they were detached for any purpose from the rest of the fleet. The grade was abolished by Congress in 1899, when all commodores became rear-admirals. While there is no actual grade of commodore in the British navy, it is by courtesy applied to the commander of a flotilla of submarines, or to the captain in command of a squadron. The word is also a title given in courtesy to the president of a yachting club, or to the senior captain of a line of merchant vessels.

COMMODUS, kŏm′ mō-dŭs, **Lucius Ælius Aurelius,** Roman emperor: b. 161 A.D.; d. 31 Dec. 192. He was the son of Marcus Aurelius Antoninus and gave early proofs of his cruel and voluptuous character. On the death of Marcus Aurelius, 17 March 180 A.D., Commodus ascended the throne. A conspiracy against his life in which his sister Lucilla played a prominent part, having been discovered in 183, he showed himself a more execrable monster than even Caligula, Nero or Domitian. For his amusement he cut asunder persons, put out their eyes, mutilated their noses, ears, etc. His brutal character made him jealous of all those who had risen to prominence during his father's reign, and most of them were put out of the way. He was endowed with extraordinary strength, and often appeared in imitation of Hercules, dressed in a lion's skin, and armed with a club. To fill the treasury, exhausted by his extravagances, he imposed unusual taxes upon the people, sold governments and offices to the highest bidder, and pardoned criminals for money. To display his strength and skill in arms he appeared publicly in the amphitheatre. He is said to have fought in this way 735 times, and as his opponents were armed with weapons of tin or lead, while he was encased in impenetrable armor, he had naturally an easy victory on every occasion. In his combats with wild beasts he was securely protected by a screen of net work, through which he hurled his darts or shot his arrows. A part of the city having been consumed by fire, and the people reduced to despair by famine, disturbances broke out, and the Emperor was obliged to consent to the death of his minister, Cleander, who was charged with being the author of these calamities. He demanded that he be himself worshipped as a god under the title of Hercules Romanus. Commodus was strangled by the gladiator Narcissus, who was hired to commit the deed by Marcia, the mistress of Commodus, who had plotted with Lætus, the prefect, and Eclectus, the imperial chamberlain, to put him out of the way, and on the news of his death, which was reported to be the consequence of an apoplexy, the Senate declared him an enemy of the state, ordered his statues to be broken to pieces, and his name to be erased from all public inscriptions. Rome was indebted to him for her handsomest baths — the Thermæ Antonianæ. He established also an African fleet, in addition to the Egyptian one, for the purpose of supplying the city with corn.

COMMON, that which belongs as a privilege or right equally to more than one, to many, or to the public at large; free to all; general; universal; public; having no separate owner; as, the common weal. In Scotts Law, common good, taken in its widest sense, signified all the properties of a corporation over which the magistrates had a power of administration «solely for behoof of the corporation.» In the sense of that which is for the general public the Court of Common Pleas is often called the «Common Bench.»

«In common» has the legal sense of equal

with another or with others, or for equal use or participation by two or more. Hence the old expression «tenants in common» which is still in use.

The word is also applied to an open and (generally) unenclosed space, the use of which is not restricted to any individual, but is free to the public or to a certain number. In most of the cities and towns in the United States there are considerable tracts of land appropriated to public use. These commons were generally laid out with the cities or towns where they are found, either by the original proprietors or by the early inhabitants.

In logic the word is applied to terms or names, in opposition to individual, singular or proper. «Common terms, therefore, are called 'predicables' (namely, affirmatively predicable), from their capability of being affirmed of others; a singular term, on the contrary, may be the subject of a proposition, but never the predicate unless it be of a negative proposition (as for example, the first-born of Isaac was not Jacob); or, unless the subject and predicate be only two expressions for the same individual object, as in some of the above instances.»

COMMON ACCIDENT, a term in logic used to denote a character or predicate which is nearly always or, it may be, always found in a certain kind of subject. See LOGIC.

COMMON ASSURANCES, *in law,* the legal evidence of the transfer of the title to property, as deeds or wills. In most countries such evidences must be registered in conformity with the provisions of the law in order to become operative and effective.

COMMON BENCH, the Court of Common Pleas. See COMMON.

COMMON-BUD, a term used in botany to indicate a bud which is, at one and the same time, a leaf-bud and a flower-bud.

COMMON CARRIERS, such as carry goods for hire indifferently for all persons. The term includes carriers by land and by water and is sometimes applied to those who regularly and as a matter of business convey messages. On the one hand they comprise stage-coach proprietors, railway companies, truckmen, wagoners and teamsters, car-men, porters and express companies, whether such persons undertake to convey goods from one portion of the same city to another, or through the whole extent of the country, or even from one country to another; and on the other hand they include the owners and masters of every kind of vessel or water-craft, who undertake to carry freight of any kind for all who choose to employ them, whether the extent of their navigation be from one continent to another or only in the coasting trade, or whether employed in lading or unlading goods or in ferrying, with whatever motive power they may adopt. (Story, Bailments, §§ 484–496). Common carriers are liable for all damage or loss during the transportation from any cause, except the act of God or the public enemy. Common carriers both by land or water, when they undertake the general business of carrying every kind of goods, are obliged to carry all which offer, and if they refuse without just excuse, they are liable to an action. Common carriers may qualify their common-law responsibility by special contract. The bill of lading is usually the written evidence of the contract between the parties. The responsibility of the carrier begins on receipt of the goods from the owner. Carriers of passengers are not held responsible as insurers of the safety of those whom they transport, as common carriers of goods are. They are, however, bound to a high degree of care in the selection of appliances, employees, etc., in order to secure the safety of their passengers. Extensive powers over carriers, especially in regard to the fixing of rates, are possessed by the Interstate Commerce Commission, appointed by the act of 1887. Consult Fetter, 'The Law of Carriers of Passengers' (Saint Paul 1897): Hutchinson, 'Treatise on the Law of Carriers' (Chicago 1891); Sealy, D. F., 'Selected Cases on Bailments and Carriers' (1927). See COMMERCE, INTERSTATE.

COMMON COUNCIL, the council of a city or corporate town, empowered to make by-laws for the government of the citizens. In American cities the city council is generally composed of but one chamber, but the name may be, and sometimes is, applied to a body consisting of two cameras. They are elected by the people.

COMMON DIALECT, a name given to the common tongue of the educated classes in Greece and other countries after the death of Alexander the Great. This «dialect» which was both written and spoken was also known as the «Hellenic dialect,» a form of the Greek tongue much like pure Attic, which, with the writings of Aristotle, begins to change into the «common dialect.» The latter had pretty well changed into Byzantine Greek at the beginning of the 5th century.

COMMON DIVISOR, or **COMMON MEASURE,** *in mathematics,* a number that divides each of two or more given numbers exactly, that is, without leaving a remainder in the form of a whole number, fraction or decimal. The *theory of divisors* is that part or section of the theory of numbers relating to their divisibility; while the *method of divisors* is the means of finding the commensurable roots of an equation. By this method they are rendered integral, after which they are sought for among the factors of the absolute term.

COMMON FIELD, a term generally used in the plural to denote the arable land of a village community in ancient times. These lands were divided into three long, narrow strips and were cultivated in co-operation though the land was alloted to several owners. In French Canada and those parts of the south of the United States which formerly belonged to France small tracts of land, usually quite narrow and long, fenced in and cultivated by the inhabitants in general, were long known by the name of the common land or common field.

COMMON LAND. a term loosely used to indicate that land is held in severalty but used in common. It also has the signification of land owned by the community and used as a waste or open land for common pasturage. Such land has not been appropriated to cultivation by an individual. There was a great deal of such land in all the Latin-American countries less than half a century ago; and in certain retired communities considerable of it

still exists, more especially in the Latin-American countries. It was a common manner of holding land among all primitive peoples given to the cultivation of the soil on a scale extensive enough to make the possession of land a consideration in the life of the community or of the individual.

COMMON LAW, the great body of unwritten law in England and the United States as distinguished from the written or statutory law. The ultimate sources of the common law of England are the usages and customs which were observed by the barbarous ancestors of the Saxon and Norman conquerors, and administered in their rude forest courts long before the beginning of their historic records. This origination is not peculiar to Teutonic law. «Custom is law,» said Cicero. Usage, or rather the spontaneous evolution by the popular mind of rules, the existence of which is proved by their general observance, is the oldest form of law making. The criminal law was a major part of the early English as of every other rudimentary legal system. All law was penal in its beginning, and the licensed revenge of injured parties, next to popular opinion, was the most powerful means of enforcing customary rules of conduct in loosely organized primitive communities. Indeed, compounding for injury was the beginning of criminal and, also, of civil procedure; the privilege of paying «weregild» to buy off the avenger passed by almost imperceptible stages into the obligation to pay damages for breaches of contract as well as for injuries resulting from distinctively tortious acts.

The late Justice Oliver Wendell Holmes, Jr., of the United States Supreme Court, in his 'Common Law,' first published in 1881, illustrated this evolution, and also the almost perfect parallel in the development of the Roman and Teutonic systems. A few examples of the early law of liability drawn from each of these systems may be useful as well as interesting. In the Twelve Tables (B.C. 451) it was provided that if an animal had done damage it must be surrendered to the injured party or his personal representatives, or compensation paid for the damage done. The same rule was applied (consult Gaius, 'Institutes') to the torts of children or slaves. The underlying idea in all these cases was the surrender of living things, from which an injury had proceeded, to the vengeance of the obligee; the owner's privilege to pay damages in compensation being in effect a right of ransom. The forfeiture of the thing causing injury was afterward extended to inanimate objects by the Roman law; but an even more revolutionary innovation was the making of a person answerable for the wrongs of a free man in his employ as well as for injuries caused by slaves and other persons and things over which he had, or claimed, a proprietary right. Failure to observe a contractual obligation might not be considered a wrong that would excite a desire for vengeance; still, it is provided in the Twelve Tables that an insolvent debtor should be surrendered to his creditors, who, after the observance of certain formalities, obtained the right to cut up the bankrupt's body and divide the parts among themselves. Now as to the Teutonic parallels: According to the Salic Law, if a man was killed by a domestic animal, the owner was required to pay one-half the composition (weregild) which he would have had to pay to buy off the blood feud if he himself had killed the man; for the other half he was required to surrender the animal to the complainant. The same law provided for payment of one-half the customary weregild where the slayer was a slave, and for the surrender of the latter to the vengeance of the blood kindred of the slain. In more primitive Teutonic law, as in the Twelve Tables, injuries done by animals were atoned for by their surrender alone. The 'Lex Saxonica' made the master responsible for wrongs done by his bondmen at his command and, according to the Thuringian law, the master was required to pay damages for all injuries resulting from the acts of his slaves. In the Kentish laws of Hlothaere and Eadric (A.D. 680) it is provided that if a slave slay a freeman . . . . let the owner pay with 100 shillings and give up the slayer.» According to the laws of Ine, «if a Wessex slave slay an Englishman, then shall he who owns him deliver him up to the lord and the kindred, or give 60 shillings for his life.» (Consult Thorpe, 'Ancient Laws,' I, pp. 27, 29 and 149). In the laws of King Alfred (A.D. 871–901) is the provision that «if a neat wound a man let the neat (cattle) be delivered up or compounded for.» (Thorpe, 'Ancient Laws,' I, p. 79). Here we have the successive and almost identical stages through which the law of an owner's liability passed in both the Roman and Teutonic systems, from the requirement to surrender the cause of injury to the payment of compensatory damages. In Alfred's laws may be found even a curious extension to inanimate objects of the injured parties' right of vengeance. It is there declared that a tree by which a man is slain, though without fault of the owner, shall be given to the kindred; which is not unlike the custom of the Kukis, a savage tribe in southern Asia, recorded by Tyler in his 'Primitive Culture,' that, if a man be killed by falling from a tree, his relatives take revenge by felling the tree and scattering it in chips. And the idea of avenging a death on the instrument which caused it persisted in English jurisprudence up to relatively modern times. A «deodand,» the thing with which a homicide was committed, was regarded as accursed and was forfeited to the Crown, although the owner had nothing to do with the slaying. From a record (*tempus* Edward I) we learn «if a man fall from a tree, the tree is deodand; if he be drowned in a well, the well shall be filled up,» while from the days of Elizabeth downward law students have been made familiar with the proposition: «If my horse strikes a man, and afterward I sell my horse, and after that the man dies, the horse shall be forfeited.» The curse follows the deodand and nobody can acquire property therein. There is nothing in Teutonic law quite comparable in ferocity to the division of an insolvent debtor's body among his creditors, as authorized in the Twelve Tables; yet the early Teutonic law of suretyship was very severe. Down to the times of Charlemagne (800 A.D.), and later, a surety was a hostage and his life was forfeited if his principal defaulted in the performance of an obligation. «Bail is a prisoner's keeper and shall be charged for an escape, some say the bail shall be hanged in his place» — thus an opinion of Shard, a justice of the time of

Edward III, cited in Fitzherbert's 'Abridgment,' under title "Mainprise," pl. 12.

The distinction is very properly made by American and English jurists between "written" and "unwritten" law. Even before the time of Lord Chief Justice Coke the term "written" was applied almost exclusively to statutory law; but there was a written law in England before Parliament came into existence, as the collections of laws going under the names of Alfred, Canute and other kings of the pre-Norman period indicate. William the Conqueror in the fourth year of his reign (1070) promulgated the so-called "Laws of Edward the Confessor," his immediate predecessor and the last of the Saxon kings. These laws were collected by a grand committee of "wise and noble English (not Normans) learned in their laws and customs," whom William had caused to be summoned from all parts of the country. The method adopted in this case bears a distant resemblance to the enactment of laws by a legislative body; but the legislation of the Norman monarchs, who governed without parliaments, usually took the form of a *carta* or charter. The "Great Charter," or *Magna Carta,* is a glorified example. The "Laws of Edward the Confessor" are little more, however, than a collation of the laws of liability and compensation, whereof several examples are given in the foregoing paragraph. More instructive, though less authentic, than the collection just mentioned, is one bearing the name of the "Laws of Henry I," a son of the Conqueror, who reigned from 1100 A.D. The work is a compilation, made by an unknown hand, of many things to be found in the earlier enactments, though some parts are extracted from the civil and canon law and there are several express references to the laws of the Salic as well as of the Ripuarian Franks. Notwithstanding its defects it provides better means of forming an opinion of the nature of law among the early English than does any other extant document. The impression given is, that there was a body of laws and customs sufficiently well ascertained for practical purposes, but that when anything in the nature of a legal principle or definition was required they were at the mercy of any person whom they respected as a learned man, and who was prepared to lay down a rule on his own or any other authority or no authority at all. Roman law must have been the source of many such legal principles, for none other was then in existence. The extent to which the civil law was drawn upon, probably, will never be clearly ascertained. The compilation of the "Laws and customs of England," which bears the name of Glanvill, Chief Justiciar in the reign of Henry II (1154–89), does not anywhere cite or refer to the Roman law as authority. It did not need to. For men to buy and sell, borrow and lend, hire and let, is in the nature of things and, in an even indifferently well-ordered community, customs and usages, whereby men will regulate the conduct of their affairs, are bound to spring up. Glanvill's commentary on these transactions of ordinary life is in complete accord, however, with the Roman law. The principle of the *jus civilis* respecting "real contracts," that the delivery of the object of an agreement created an obligation on the part of the receiver to complete the contract, had taken firm root in England before Bracton's time. The Roman principle as to the liability of the master for the default of his servant was first adopted in a case decided in the time of Edward III (reigned 1327–77) but the authority relied upon is the law of Oleron. The original English rule, as stated in the "Laws of Henry I," was, that "the lord has to pay unless he can clear himself of complicity"; the Roman law held the master responsible even though himself guiltless of wrong. The Roman origin of the existing English rule on the subject appears clearly from the fact that for more than 400 years past every English court and every English law writer has repeated the shallow arguments whereby the Roman jurists have defended the principle of liability without default. While it seems rather illogical to call "unwritten" a body of laws recorded in thousands of volumes of printed reports and treatises, the distinction between this and the "written" law incorporated in statutes is completely justified. A statute law takes effect only from the time of its enactment and, generally speaking, affects only legal rights subsequently created or acquired. An "unwritten" law is presumed to have been always in effect, and to be applicable to rights acquired, or existing, in the remotest time past. When a court renders a decision in accord with an immemorial custom or usage it does not make a law; it merely records the fact of its existence, though the legal rule thus established may never before have been written down. The qualification "unwritten" is, therefore, quite properly given to such law. In their origin, indeed, legislative enactments and judicial pronouncements are indistinguishable. The sovereign himself, in theory and often in fact, dispensed justice in his court, and judicial pronouncements the same as royal ordinances or *cartæ* emanated from the king. The investiture of distinct officials with judicial functions, however, took place at an early date, and forms of action and rules of procedure, apparently, had been invented by the time of Henry I. Glanvill in the succeeding reign speaks of the "Action of Debt" as ancient, and the "Action on Covenant" was probably established contemporaneously. A writ of "Debt" was a very primitive device, being a bare statement that so and so owed the plaintiff so much. It was employed in actions to enforce all legal obligations whether arising out of contracts (covenants accepted) or out of torts. A general denial by the defendant sufficed to defeat the action. It was for this reason that other writs of action (in assumpsit and in trespass, for instance) were invented. Special pleading became a fine art, giving opportunities for the exercise of refined legal ingenuity — the purpose being to narrow down the issue in a case to a single question of fact and a single point of law — and on this basis the structure of the common law has been mainly erected. Bracton, whose "Leges Angliæ" were written about 1258, drew the first four chapters of his work from the Roman law, but nine-tenths of his treatise is taken from the plea rolls of the courts. His extant "Note Book" contains a record of more than 2,000 cases, of which over 500 are cited in his work, and 350 folios of the latter, out of a total of 444 folios, are

devoted to the law of «Actions.» From this time forth the law reports, the issue of which increases in volume from year to year, became the repositories of the judicially declared unwritten law. In the «Year Books» the report of a case generally consists of a statement of the form of action, the plea, a summary of the facts and the judgment of the court, whether for the plaintiff or the defendant; the rule of law involved must usually be inferred. From the time of Coke judicial opinions became more and more elaborate and, nowadays, they are frequently of inordinate length even in cases involving no point of particular novelty or importance, while the reporters follow no discoverable principle of selection in making up their volumes. The Roman system of laws begins and ends with a code. The theoretical descent of this body of law from the Twelve Tables and the theoretical ascription of the common law to immemorial unwritten tradition were the chief reasons for the difference in the development of the two systems.

The early Teutonic law scarcely recognized individual property. A man might own his spear, his sword, his shield and other weapons of offense or defense; but the *allod*, or domain of each household, was incapable of being disposed of by sale or testament, being strictly reserved to the kindred. Even chattels were regarded as common possessions, the family partaking somewhat of the character of a corporation, of which the *pater-familias* was the trustee, and the members of which were clothed with certain inalienable rights. Under the feudal system a new viewpoint was taken with regard to property in land. The Gothic, Frankish and Saxon chieftains, who conquered the domain of the decadent Roman Empire, parceled out their conquests among their retainers in fiefs. But the land thus distributed was not owned by the person in possession. It was merely held in tenure by way of reward for prospective, as well as past, military service. When the holder of a tenure died or failed in his loyalty the property, which had theoretically remained vested in the sovereign, reverted absolutely to the latter. The succession to land was in the disposition of the overlord, who could demand homage and fealty from the successor as conditions of investiture, and who would also see to it that the latter was a person capable of fulfilling his military obligations. The preference of males in the line of descent and the practical disinheritance of all but the first-born were natural outgrowths of feudal institutions. The privilege of conveying land without regard to these limitations and the view of a will, which regards it as conferring power to divert property as the fancy of the testator may dictate, are not older than the later portion of the Middle Ages. The modification of the strict feudal rules of inheritance in England was an achievement of the courts and lawyers, which was not obtained without conflict with the landed interests represented in Parliament. For instance, where a conveyance or devise of land was made to a person «and his heirs,» the courts held this condition to be satisfied when an heir was born to the grantee or devisee; though the heir might subsequently die, the right to dispose of the land by sale or will was complete. The statute 'De Donis' reversed this rule of the lawyers and declared that in the event of the non-existence of an heir on the demise of the holder of a fee in land the title reverted to the grantor. The feudal law recognized entails, but the lawyers invented the process of «fine and recovery» whereby an entail could be defeated. Finally, by the rule in Shelley's case, the word «heirs» in a conveyance of land was held not to be a word of limitation curtailing the grantee's right of disposition, unless so qualified that another interpretation would necessarily have to be given to it. Another legal fiction, whereby the alienation of estates in land was facilitated, was introduced by the equity jurisdiction. The holder of a fee simple was permitted to create a «use» by conveying the legal title to another, with the understanding that the grantor was to retain an equitable estate therein. The court of chancery would enforce this understanding against the grantee, who held the legal title, and a «use» was capable of testamentary disposition. In the event of intestacy the «use» descended to the heir. Finally Parliament made a statute declaring the beneficiary of a «use» to be the real owner and permitting the disposal of estates in land by will. In this roundabout manner were «tenures» converted into absolute rights of ownership. In theory the holder of a tenure continued to owe homage to his immediate landlord, though by Coke's time the obligation to perform military service as a condition of holding had become in the main a legal fiction. A tenancy in fee was tantamount to ownership, and there were lesser estates, as copyholds, in the creation of which the possibility of the tenant trailing a pike in the service of his liege was never thought of. A copyholder was simply a lessee who paid rent, and a lease had become simply a contract. The provision made by law for the widow was attributable to the exertions of the Church, which achieved one of its greatest triumphs when the express promise exacted from the husband at marriage to endow his wife was converted into a legal right and the principle of «dower» was grafted on the customary law of all western Europe. A milestone in the history of the common law was placed when Thomas Littleton's famous treatise on 'Tenures' was published (about 1481). This work, written in Norman French, was the first really systematic exposition of the English law of real property. It contained not merely a clear and accurate account of the great variety of tenures then known in England, but of the rules with respect to the alienation and inheritance of land, including the law of primogeniture and entailment, as well as the rights incidental to land holding, as easements, or the right to the usufruct. Also the property rights growing out of personal relations between the parties, for instance, a husband's estates by curtesy and a wife's right of dower. Also the absence of rights resulting from a low position in the social order, as, for example, villeinage. Also the law of actions on 'Covenant' and of 'Fine and Recovery.' In fact, for a community which was just emerging from the feudal stage of organization, and in which land alone was, literally speaking, considered *real* property, the law of tenures contained a practically complete

system of rules for the governance of society in its ordinary civil relations. It was this that moved Camden, in his 'Britannica,' to speak of Littleton as "the famous lawyer, to whose 'Treatise on Tenures' the students of common law are no less beholden than are the civilians to Justinian's Institutes." Coke called the book "the ornament of the common law, the most absolute and perfect work that ever was written in any human science"—and, when he had drowned the original rivulet of text in an inky flood of commentary, he put forth the product (in 1628) as the 'First Institute of the Law of England.' In this form the work for nearly two centuries remained an authoritative textbook on the common law and, though now almost wholly obsolete, it still has undeniable historic value.

The legislative or statutory contributions to the common law have been massive in quantity and of transcendent importance in their subject matter. It is impossible to even mention more than a few, which stand out above the rest in the formative influence they have exerted. The statutes of Mortmain and Charitable Uses were designed to prevent perpetuities. They marked the growth of the right to alienate land and the gradual undermining of the feudal system. Frequent additions and amendments were required to overcome the ingenuity exercised by the lawyers to evade the statutes against the formation of ecclesiastical and other latifundia. Of equal importance, though in a quite different direction, was the Statute of Frauds. A distant progenitor of this was the provision of Magna Carta which required *secta* (witness proofs) for parol debts, and set a limit to contentious and vexatious litigation by forbidding suit for such debts except within the traditional limits of the *secta*. The statute of Charles II (1677) for the Prevention of Frauds and Perjuries requires written instruments as proof in many classes of contracts and in all contracts not to be performed within a year. The imperfection and danger of oral testimony as proof of past transactions make this one of the most salutary legislative measures in English jurisprudence. The Statute of Limitations, passed during the reign of James I, should also be mentioned. The barring of stale claims from litigation after long lapse of years, when oral and other evidence concerning the transaction was no longer procurable, is the only effective means of quieting titles and assuring the members of society from provocative interference with other long enjoyed rights and promoting the peace. Other sources of the common law, which may here be conveniently mentioned, are the charters granted to municipalities and trading companies, many of the "liberties" granted in these having become general rules of law. The "Law Merchant" was a body of usages common to traders in all parts of Europe relating mainly, of course, to mercantile transactions. The law was laid down by the merchants themselves. The traders of the later Middle Ages were cosmopolites and their established customs and legal rules were observed by all alike, irrespective of nationality. The law was administered by special tribunals —in England by the Courts of Staple and Piepowder Courts. It was administered as distinct from the Common Law even after Coke, in whose time the ordinary law courts had begun to take jurisdiction of controversies between traders. The customs had to be proved as facts in each case. During the presidency of Lord Mansfield over the King's Bench, the Law Merchant was finally incorporated with the common law (see COMMERCIAL LAW). Finally, the equity jurisdiction assumed by the lord chancellors at an early date, and continually broadened, wielded a tremendous influence on the matter, form and practice of the common law; more particularly with regard to women, children and other persons of imperfect legal capacity. This department of law reached its full development in the 18th century under Lord Eldon (see EQUITY). The laws of marriage and the family, of consanguinity and testamentary succession had their origin in the civil and canon law and until modern times (in England) they were administered by the ecclesiastical courts. The title "Surrogate," quite common in the United States, was originally that of the officer who presided over the probate of wills in the Ordinary's Court.

In the domain of constitutional rights the common law has drawn its tenets from a variety of sources; but all of them are purely English. The right of freemen to representation in their own government is traditional, and the Saxon "witenagemots" and Norse "folke things" were the prototypes of Parliament and Congress and all other later legislative assemblies. Immemorial usage also is the basis of the right to trial by jury, though this is also confirmed by Magna Carta. The English Bills of Rights, as their names import, were acts of Parliament, though in America they have generally been embodied in written constitutions, State and Federal. The independence of the judiciary of royal prerogative and the answerability of judges to God and their own conscience, and to no other authority whatsoever, were pronounced in a defi of King James I by Lord Chief Justice Coke. The latter also anticipated the United States Supreme Court by nearly 200 years in passing upon the constitutionality of statutes, saying that "the common law doth control acts of Parliament and adjudge them void when against common right and reason." The fiction that English sovereigns rule by divine right was shattered at least four times, when reigning monarchs were deposed and it was shown that kings in England ruled only by grace of the law and of Parliament. This was the complexity of political liberties and public and private rights, known as the common law, which the English colonists carried with them to America as a cherished heritage. It may suffer in the estimation of precisians because of its lack of form; its nomenclature, as has been truly said, is "a mosaic of many languages"—and the law itself, "except so far as it has been deduced with much logical punctiliousness from the theory of feudal tenure," is little more than a collection of rules strung together on a slender thread of analogy, through which the practitioner must be content to find his way by the help of indices, abridgments or so-called "Digests" arranged in alphabetical order. On the other hand the case against the embodiment of the law in a code, where the rules would be restated in *the language of the codifier*, is a strong one. A code, being inflexible in its character, prevents true growth

in the law. Discussions in court would turn on the interpretation of *words* employed in the codification instead of the examination of legal principles. Moreover, an uncodified system of law can be mastered by the student whose scientific equipment enables him to cut his own path through the tangled growth of enactment and precedent and, so, to codify for his own purposes. The common law as it existed at the time of the Declaration of Independence, including the acts of Parliament in so far as they were not repugnant to the rights and liberties contained in their respective constitutions, was formally adopted in all the original States of the Union and by most of the commonwealths subsequently admitted as States. Louisiana, where the 'Code Napoleon' prevailed at the time of its admission to statehood, is an exception. Feudal tenures, the right of primogeniture and entails were abolished in all the original States, and were never recognized by the common law in America. Though the Constitution of the United States in no words adopts the common law, its provisions no less recognize the existence and continuance thereof as the law of the States, with which the national government might not interfere. But even statutes are to be construed with reference to the common law, for it is not to be presumed that the legislature intended to make any innovation upon the common law further than the case absolutely required. This rule of construction has been held applicable to acts of Congress. The Federal courts have no jurisdiction over common law crimes; however, in the trial of actions between citizens of different States involving ordinary legal rights these courts necessarily take cognizance of the laws of the States and of the principles of the common law governing the cases thus brought before them. The Constitution of the United States, together with foreign treaties and acts of Congress made under its authority, are the supreme law of the land. In the States their constitutions, statutes and the common law rank in authority in the order given. When the American colonies had achieved their independence Blackstone's 'Commentaries on the Laws of England,' which Horne Tooke called "a good gentleman's law-book, clear but not deep," had not long been off the press. In it the emphasis is still laid on the rights pertaining to land ownership though, under the titles "Rights of Persons," "Rights of Things" and "Private Wrongs," he classified, not very scientifically, the law of possession and ownership, contract and succession to property by sale, assignment or inheritance, and the law of trespass, negligence and fraud. Bentham criticised the commentators' overstrained, courtly praise of his subject and the obscurity and confusion of his fundamental ideas with irresistible point and vigor and a racy sense of humor. Admitting all these defects, the fact remains that "Blackstone first rescued the common law from chaos and did exceedingly well, for the end of the 18th century, what Coke tried to do, and did exceedingly ill 150 years before." He gave an account of the law as a whole capable of being studied, not only without disgust, but with interest and profit. Another rich mine of the common law was laid open to the young American commonwealth in the decisions of Lord Mansfield, who during his 30 years' incumbency of the office of Chief Justice of England (1756–88) reduced the mercantile law to a systematic and harmonious form. The rise of the United States early in the 19th century to the position of a maritime power second only to Great Britain, and the long-continued state of war on the high seas during that period, naturally produced litigation pertaining to shipping and commerce. Accordingly, the early American law reports are noteworthy for the large proportion of judicial opinions they contain on bills of exchange, bills of affreightment, charter party and, particularly, marine insurance. Little was left for succeeding courts to add to the law on the last named topic. The growth of trade and industry made a form of association desirable, to which many could subscribe capital, with liability limited to the amount of their subscription; therefore, the adaptation to the requirements of manufacturing, trading and other business enterprises of the corporation, which had theretofore served mainly for the administration of charitable, ecclesiastical and educational foundations, of municipalities and such politico-commercial entities as the East India Company. The institution and development of the business corporation are to be counted among the great achievements of American jurisprudence. The partial emancipation of married women from the disabilities of coverture was begun by legislative enactments in the States in the 40's of the last century. In the systematization or codification of the substantive law no great progress has been made in the United States. The law on such topics as negotiable instruments, bills of lading and sales has been reduced to the form of proposed statutes, which have been recommended to the States for adoption—and the first mentioned has been almost unanimously adopted, so that the law on this subject is practically uniform throughout the country. New York led the way in the codification of the rules of civil procedure, with incidental simplification and the abolition of the distinction between common law and equity pleadings. The example has been pretty generally followed and the penal law and criminal procedure have likewise been codified in many States. See COMMERCIAL LAW; CRIMINAL LAW; EQUITY; FAMILY LAW; HUSBAND AND WIFE; JURISPRUDENCE; MARITIME LAW.

STEPHEN PFEIL.

COMMON LIFE, Brethren of the, or THE COMMON LOT, a religious institute founded about 1376 by Geert or Gerhart Groot at Deventer in the Low Countries. Groot on a visit to the noted mystic Ruysbroek was so impressed by the spectacle of peace and joyful co-operation shown in the community of Austin friars over which Ruysbroek presided that he resolved to form a society embracing both clerics and laymen who, without taking the monastic vows, should lead an austere Christian life in common. One of the aims of the brotherhood was to conduct schools for the religious and moral education of children, and their labors in that field were so successful and so highly appreciated that their school at Hertogenbosch had 1,200 pupils and another school even a larger number. Establishments of the brotherhood were founded in Italy, Sicily and Portugal, and in 1430 there were in existence 130 societies of the institute. At the same time there was formed a similar institute for women: here the superior of each society was styled the Martha. Among the eminent characters who were members of the brotherhood or alumni of their schools were Thomas à Kempis, Nicolaus Cusanus and Erasmus. Many of the "obscurantist" letters in the 'Epistolæ Obscurorum Virorum' purported to be written by members of the Deventer Brotherhood, who are made to appear as irredeemable blockheads.

COMMON METRE, a term used in psalmody to indicate a special form of iambic stanza, consisting generally of four lines, with eight and six syllables alternately to the line. It received its name because it was actually the "common metre" in use in the metrical version of the psalms. Common long metre, in psalmody, consists of a six-line stanza, combining a common-metre stanza with half a long-metre stanza; while common particular meter, consisting also of a six-line stanza, has six syllables in the third and sixth lines and eight syllables in the remaining lines.

COMMON PLEAS, Court of. See COURT.

COMMON PRAYER, Book of. See BOOK OF COMMON PRAYER.

COMMON RECOVERY is, in law, a collection suit instituted by the intended grantee of land against the intended grantor in which the land is suffered to be recovered by the grantee. This device, which was once in common use to avoid legal restraint on alienation by conveyance, is now gone out of use, as additional provisions of the law have made its employment impracticable.

COMMON SCHOOLS, schools for the common people or the people in general. It is only in modern times that education has spread to the masses. In ancient times education was generally confined to a limited class and it was only after the Reformation that common schools came into being. At first they were under ecclesiastical direction, but were gradually secularized and placed under the control of the state. Most of the American colonies established common schools and by 1825–50 the free school system developed. Since then the system has extended to all the States and the scheme of instruction has been greatly enlarged. In the United States, therefore, the term means schools to which all persons within certain ages, except criminals and those with contagious diseases, may attend and implies, moreover, that such schools are supported and controlled by the people and charge no tuition. At first the term was confined to elementary and secondary schools, but there is a growing tendency to include in the common schools of the United States all grades and degrees from the kindergarten to the university. According to the 'Statistical Abstract of the United States,' published by the Department of Commerce, there were in the United States in 1937, a total of 27,160,037 persons between the ages of five and 17 years. Of these 20,765,037 were enrolled in the elementary schools of the country, while the average daily attendance upon the schools was about 18,000,000. Teachers employed numbered 847,120 of whom 161,949 were males and 685,171 were females. Salaries of teachers amounted to a total of $1,075,313,000, while the total expenditure for school purposes that year was $2,311,178,000. The average duration of schools in days was 173.4. The common school system in general use in the United States has been extended into Puerto Rico, Hawaii and the Philippine Islands. Cuba has adopted the same system. See EDUCATION, HISTORY OF; EDUCATION IN THE UNITED STATES; EDUCATION, ELEMENTARY, SECONDARY, etc. See also PUBLIC SCHOOLS; PARISH SCHOOLS.

COMMON SENSE, the philosophy of the so-called Scotch school of philosophy founded by Thomas Reid (1710–96), who aimed to establish a series of fundamental truths indisputable as primitive facts of consciousness. He taught that the general consent of mankind as to the existence of an external world, as to the difference between substance and qualities, between thought and the mind that thinks, is sufficient to establish the reality of a permanent world apart from ourselves; and he maintained that sensations are not the objects of our perception, but signs which introduce us to the knowledge of real objects. The name is applied in colloquial language to that power of mind which arrives at correct conclusions, even if the thinker has no knowledge of laws of thought.

COMMON-TIME, time with two beats in a bar or any multiple of two beats in a bar. The beats may be of the value of any note or rest or compound of notes and rests, providing the sum required by the time sign be exactly contained in each bar. Common-time is of two kinds, simple and compound. Simple common-time is that which includes four beats in a bar, or any division of that number, or square of the number of the divisions. The signs used

to express simple common-time are the following: $\frac{2}{1}$, $\frac{2}{2}$, $\frac{2}{4}$, $\frac{4}{4}$, $\frac{2}{8}$, and the characters C and C̸. In these signs the upper figure denotes the quantity of notes required in the bar, and the lower figure the quality of the notes. Compound common-time is expressed by the signs $\frac{6}{4}$, $\frac{6}{8}$, $\frac{12}{8}$, such signs meaning two or four beats of three crotchets or quavers to each beat.

COMMONS, John Rogers, American economist: b. Hollandsburg, Ohio, 13 Oct. 1862. He was graduated at Oberlin College with the degree of A.B. in 1888, and received the degree of LL.D. from the same institution in 1915. He studied at Johns Hopkins University 1888–90 and became professor of economics and sociology at Oberlin College 1892, at Indiana University 1893–95, Syracuse University 1895–99, and at the University of Wisconsin since 1904. He was director of the Bureau of Economic Research 1899–1901, and is director of the American Bureau of Industrial Research since 1904. He was investigator for the United States Industrial Commission 1901–02. In 1911 he was appointed a member of the Wisconsin Industrial Commission; and in 1913 he published a report of the work of the Milwaukee Bureau of Economy and Efficiency. He is the author of articles on wealth, labor, representation, etc., in scientific and other journals, and of 'The Distribution of Wealth' (1893); 'Social Reform and the Church' (1894); 'Proportional Representation' (1895, rev. 1907); 'Trade Unionism and Labor Problems' (1905); 'Races and Immigrants in America' (1907); 'Labor and Administration' (1913); 'Labor Legislation' (with John B. Andrews, 1916). He edited 'Restriction of Output by Employers and Employees' (the 7th special report of the United States Commissioner of Labor, 1904). He was also one of the editors of 'A Documentary History of American Industrial Society' (1910); 'History of Labor in the United States' (1917); and wrote 'Principles of Labor Legislation' (with John Andrews, 1917).

COMMONS. The commons of Great Britain, in a general sense regarded as comprising all such men in the kingdom as had not seats in the House of Lords, and every one of whom had a voice in Parliament, either personally or by his representatives. With women now enrolled in the parliamentary franchise, the Commons must be regarded as including both sexes. Commons in Parliament is the lower House, the third estate of the realm, and consist of representatives elected by the counties or divisions of counties, and by the cities and boroughs. In the election of representatives anciently all the people had votes; but in the 8th and 10th of King Henry VI, for avoiding tumults, it was enacted that in counties none should vote but such as were freeholders, did reside in the county, and had 40s yearly revenue, equivalent to nearly £20 a year of the present money; the persons elected for counties to be *milites notabiles,* at least esquires or gentlemen fit for knighthood; native Englishmen, or at least naturalized, and 21 years of age; no judge, sheriff or ecclesiastical person to sit in the House for county, city or borough. The House of Commons, in Fortescue's time, who wrote during the reign of Henry VI, consisted of upward of 300 members: in Sir Edward Coke's time their number amounted to 493. At the time of the union with Scotland, in 1707, there were 513 members for England and Wales, to which 45 representatives for Scotland were added; so that the whole number of members amounted to 558. In consequence of the union with Ireland, in 1801, 100 members were added for that country; and the whole House of Commons therefore consisted of 658 members. By the reform bill of 1832 the number of members was altered as follows: 500 for England and Wales, 53 for Scotland and 105 for Ireland. The reform acts of 1867 and 1868 introduced a further alteration, the numbers being 493 for England and Wales, 60 for Scotland and 105 for Ireland; by the act of 1919 Commons representation became 707, reduced in 1922 to 615, including 13 from Northern Ireland. See GREAT BRITAIN—*Parliament.*

COMMONWEALTH, the state or prosperity of a country without any reference to the form of government under which it may be at the time. Owing to the semi-independent position of the States of the American Union the term commonwealth is of frequent application to the various members of the great Federal government, which itself is spoken of as the National or Federal Commonwealth in contradistinction from its constituent autonomies. In many of the States the legal proceedings against criminals, etc., are instituted in the name of the (for example) "Commonwealth of ——— *v.* John Doe."

The word is also applied to the period in the history of England during which the parliamentary army and the Protector, Oliver Cromwell, exercised the power of government. King Charles I was beheaded on 30 Jan. 1649; but if the beginning of the commonwealth be deferred to the time when Oliver Cromwell became Protector, then its beginning was not till 16 Dec. 1653. It received an all but fatal blow by the death of its great chief, 3 Sept. 1658. On 22 April 1659, Richard Cromwell, his incompetent son and successor, resigned, and on 29 May 1660, Charles II was restored to the throne. The Commonwealth of Australia, embracing the states of New South Wales, Victoria, Queensland, South Australia, West Australia and Tasmania, was established by act of Parliament passed 9 July 1900, and proclaimed at Sydney, 1 Jan. 1901.

COMMUNALISM, the theory of government by communes or corporations of towns and districts, adopted by the advanced republicans of France and elsewhere. The doctrine is that every commune, or at least every important city commune, as Paris, Marseilles, Lyons, etc., should be a kind of independent state in itself, and France merely a federation of such states. This system must not be confounded with "Communism" (q.v.), with which, however, it is naturally and historically allied, though the two are perfectly distinct in principle.

COMMUNE, kŏm'mūn, the unit or lowest division in the administration of France, corresponding in the rural districts to the English parish or township, and in towns to the English municipality. In France there are about 38,000 communes, with a considerable measure of self-government, with the power of holding property, etc. Each commune has a council elected by universal suffrage, and the council is pre-

sided over by a *maire* and one or more *adjoints* or assistants. In the larger communes the *maire* is selected by the central government out of the members of the council; in others he is appointed by the prefect of the department. The central government, through its officials, exercises generally a very large control over the affairs of the commune.

The rising of the Commune of Paris in 1871 should not be confounded with «Communism» (q.v.). It was a revolutionary assertion of the autonomy of Paris; that is, of the right of self-government through its commune or municipality. The theory of the rising was that every commune should have a real autonomy, the central government being merely a federation of communes. The movement was based on discontent at Paris, where the people found themselves in possession of arms after the siege of the Germans. The rising began on 18 March 1871, and was only suppressed 10 weeks later after long and bloody fighting between the forces of the commune and a large army of the central government; 6,500 Communists having fallen during 20–30 May, and 38,578 being taken prisoners. Consult Du Camp, *Les convulsions de Paris* (4 vols., Paris 1878–79); Lessagaray, *Histoire de la Commune* (Paris 1896); March, *History of the Commune of 1871* (London 1896).

COMMUNICATIO, kŏm-mū-nē-kā'shĭ-o, or **COMMUNIO, Idiomatum,** ĭd-ĭ-ō-mā'tŭm, a term or phrase hardly capable of translation into English, which is used to signify the appropriation mutually of divine attributes to Christ as man, and of human attributes or human affections to Christ as God because of the hypostatic union of the divine nature and the human nature in Christ; thus, we say «God died for us,» and the mother of Jesus is *theotokos, deipara,* mother of God. *Idioma,* plur. *idiomata,* is Greek equivalent to Latin *proprietas,* and means that which belongs to one, an attribute. The theological phrase in Greek is *antidosis idiomaton.*

COMMUNION, the reception of the Eucharist. In the Roman Catholic Church the Eucharist is administered to the faithful only in one kind, the species of bread. Only the priest who performs the act of consecration receives the sacrament in both kinds. In the Protestant churches the laity receive the sacrament in both kinds, and the usage of the Greek and Oriental churches is the same. The withholding of the cup from the laity was not required by the laws of the Latin Church till the Council of Constance ordered it in 1414, though by that time usage had made it an almost universal custom. Yet down to the 11th century communion under both species was universal, and as late as the middle of the 13th century Saint Thomas Aquinas notes the communion under one kind as the usage only of «some churches.» As it is purely a Church regulation, the Church can and does dispense from it, or the Church can abrogate it and bring back the original usage of communion in both kinds. Even in the earliest times communion under one kind was the rule when the sacrament was to be administered to the sick and infirm in their homes; in that case the one kind was under the species of bread, but in the same early period it was customary to administer the Eucharist to infants immediately after baptism, but only under the one species of wine. See LORD'S SUPPER.

COMMUNISM, a system of social theory and organization based upon the vesting of all property in the community, each member working according to his capacity and being rewarded according to his needs. While there is but little difference of opinion regarding the inherent merit of this concept, there is considerable difference of opinion as to its practicability, particularly in countries where there are few or no restrictions on personal ownership of property. The world's leading example of the communist program is the Soviet Union, the government and organization of which have passed through many vicissitudes, the original theses in their practical application having undergone many new developments. Considerable success has attended the program of the Soviet Union, which was inaugurated soon after the abolition of an absolute autocracy in a country where the majority of the population was but a few decades removed from serfdom, and where industrial organization, while it included some large establishments, was limited in extent and confined to a few localities.

Communism originally meant the sharing of goods and labor in common. Its history in this sense dates back at least to the early Christians. It was revived by some of the medieval religious orders (Franciscans, and Brothers of the Common Lot) and by certain heretical sects, and in more modern times has been represented in the United States by such communities as Brook Farm, New Harmony (founded by Robert Owen), and the Oneida, Amana, and Icarian settlements (qq.v.), some of which still exist.

The communism practiced in these communities differs in important respects from modern communism, or scientific socialism, as defined by Karl Marx and Friedrich Engels, and later more specifically by Lenin (qq.v.). The Marxists, while greatly admiring such leaders as F. M. C. Fourier and Robert Owen, refer to them as utopian socialists, since they tried to demonstrate how society could be transformed along ideal lines through these model communities. The Marxists asserted that to understand social change, to promote it scientifically, it was necessary to examine the given society, to learn how its forces operate. Examining the capitalist society of their day, they concluded that socialism would come about as a result of class struggles, which they declared were even then proceeding between the wage earners and the owning class for control of production and society's material resources.

The capitalist system had organized the workers in factories. They were now creating through their co-ordinated, collective labor far more goods and wealth than they had formerly created individually. But the system was caught in the contradiction of being no longer able to sell at a profit the volume of goods it was now able to produce. The factory system had created great cities, the swelling population of which was composed largely of the wage earners and their families. They constituted a great potential market for the goods produced under the factory system—a market far beyond the system's current productive capacity. Yet because of low

wages and high prices, these wage earners, who were producing the goods, were unable to buy them, beyond a bare subsistence minimum. Realizing that production and distribution depended primarily on their collective labor, they would eventually take the system over, setting up their own government—replacing the present dictatorship of the middle class by the dictatorship of the proletariat—and establish a socialist state, in which the factories and mines and railroads and the land would belong to the people. This state, the Marxists believed, would develop into a society free from wasteful class struggles, composed of freely co-operating, well-provided individuals—a communist society.

Communism as a Stage in Social Evolution.—Communism as the Marxian goal is an expected future stage in the development of society, in which the principle «from each according to his ability, to each according to his need» will be fully realized in practice. At this stage, it is anticipated, the state, as an instrument of class rule (which the Marxists consider it to be) will have «withered away» to a mere administrative apparatus. Free co-operation will prevail: coercion by the state will no longer be necessary.

Communists do not point to the Soviet Union as a full-developed communist society. Its workers are still rewarded not simply according to their needs. They are paid different amounts, depending upon the value of their work in building the new society. The Soviet Union is still a socialist state, or a state in the earlier stages of communism.

Marx and Engels, writing in a period of ascendant capitalism, traced a series of stages in the development of society from the prehistoric era of primitive communism to the communism of the future, toward which they held that our civilization is moving.

In the earliest type of human society as described by the Marxists, before the tribe, or even the monogamous family, had come into existence, our early ancestors, destitute and unorganized, learned through desperate necessity to share their meager shelter, food and clothing, and their crude stone instruments. Traces of such ancient customs were found among various peoples, including certain of the North American Indians. Little is known of life in the ancient communist society, except that it was poor and exceedingly precarious. Yet according to the Marxist picture it formed a matrix out of which has developed a succession of progressively higher forms of social organization, leading in a grand cycle to the most advanced stage as yet definable, the communism of the future.

Each of these forms of society is seen as dependent for its development upon a characteristic kind of wealth and method of production. It is these features, say the Marxists, which give a society its economic foundation and distinctive character. The use of primitive instruments of the chase and of agriculture, and the domestication of animals produced forms of wealth which could be passed on from one generation to the next. This led to the emergence of patriarchal families and of the ancient tribal kingdoms based upon them. These early monarchies, the wealth of which consisted largely in flocks and herds, were undermined through the growth of private trading and usury. Instead of killing war captives it became customary, because more profitable, to sell, or use, them as slaves. Many debtors, too, lost their freedom, becoming the slaves of their creditors. Human slaves were greatly superior to cattle. The masters of this new form of labor power became strong enough to overturn the primitive kingdoms and set up a new kind of state, which established a pattern for the great classic states of Greece and Rome. The citizens of the early Greek states achieved varying degrees of democracy. But the privileged freedom of the citizens depended upon increasing numbers of unprivileged slaves. And when, as in Rome, control passed more and more into the hands of a few patrician families, agriculture was more and more neglected, the slave system decayed, and with it the greatest of ancient empires. Many people of classic times, slaves and freemen alike, conscious of their helplessness beneath the power of the great state, idealized the epoch—ancient even then—of primitive communism, as a golden age which they hoped would some day be restored. And among the early Christians, and later, among the medieval monks, and the Gothic inheritors of the Roman lands, with their communal traditions, there were groups who sought to recreate the communist mode of life by sharing their labor and its still meager rewards.

The main cycle of social development continued with the general centralization of private wealth, the decay of agriculture, and the disintegration of the slave system. While the empire was collapsing, former slaves and destitute freemen and veterans of the wars attached themselves as laborers—serfs—to petty chieftains of the invading armies from the north, who, as under Charlemagne, became the inheritors of the Roman lands, and so the feudal system arose. The serfs, while they had certain claims upon their feudal lords, were subject to heavy exactions, and were tied to the land. Handicraft industries were fostered in connection with the many activities of the monasteries, and developed in the medieval guilds. Trade began to break down the barriers between town and town. Capital began to accumulate, and with it grew the demand for free labor. Capital, in its struggle for a free market in material goods and labor, and discontented serfs, eager to escape their feudal restrictions, became a double threat to the medieval system. Beginning with the revolutions in England and in France, a new order of society, supported by capital and wage-labor, displaced the feudal system. Capitalism won, the Marxists believe, because it could produce and distribute more goods, and reward business enterprise and labor better than feudalism.

Under the capitalist system the means of production, particularly industrial machines and combines, were more and more concentrated into large workshops and factories. Articles which had been made by a single individual were now produced by machine processes requiring the close co-operation of many workmen. Production, upon which all members of society depended for satisfaction of their needs, was becoming a social—collective—act. And yet the goods produced through the co-operative labor of thousands of workers were still being appropriated by individual capitalists for their personal gain. Herein, as Engels[1] puts it, lay the

[1] Engels, Friedrich, *Socialism, Utopian and Scientific*, p. 136.

«fundamental contradictions» in the capitalist society of his day. The system had become so efficient that it produced every 10 years or so goods in such quantity that they could not be sold at a profit. So the factories curtailed their production, or shut down outright. Many employes were thrown out of work, and fell into poverty. This recurrent cycle of overproduction and depression led to a growing antagonism between the employers and the army of industrial workers. The work inside the factories was co-operative, socialized; whereas the production system as a whole was destructively competitive, anarchistic, unplanned—a situation of which the workers were becoming more and more aware.

In the opinion of Marx and Engels these contradictions would be solved through the seizure of state power by the proletarian class when it had become informed and appropriately organized. By taking this step, they believed, the workers would transform the means of production—already largely socialized locally—into completely social, public, property. This action would give the socialized character of these productive forces «freedom to work itself out» according to rational, comprehensive planning of production and distribution for the benefit of society as a whole. The workers, in freeing themselves, would pave the way to freedom for all members of society. Thenceforth there would be only one class—of producer-consumers, and hence no occasion for class struggles. And with the disappearance of unrestrained individual competition and appropriation—anarchy of production—the coercive power of the state, being no longer necessary, would die out. «Man, at last master of his own form of social organization,» would become «at the same time the lord over Nature, his own master, free.»[2]

The communist society pictured by Engels and the process through which it was to be achieved have been further defined by Lenin and Stalin in the light of conditions and developments in prerevolutionary Russia and in the Soviet Union. The transfer of power to the proletariat, the socialist revolution, came not simultaneously in all countries, as earlier Marxists seem to have expected. Except for brief periods in Hungary and in Bavaria it materialized in Russia only. Recent developments in the Soviet Union are actual features of the Communist society forecast by Lenin. Lenin claimed to foresee, for example, not only the end of wasteful class struggles but the emergence of one great body of soviet citizens, composed of all elements in the population, who would be at once workers and owners. In the spread of education on all levels, and the increasingly intelligent participation by all in the various tasks incidental to the building of socialism he postulated the disappearance of the traditional differences between manual workers and intellectuals, and between mechanical and professional workers. In the movement for socialization of agriculture and rural electrification he anticipated the conditions for the disappearance of the distinctions between city and country. Their productivity and cultural opportunities would be equalized. The actual soviet state was expected to develop into a society in which the primitive communism of early man would reappear on an infinitely higher level, in which the developed productive forces of the society as a whole, guided by modern science and enriched by all past experience, would be made to serve the maximum good of all its members.

Communism as an Economic and Social Program.—Communism as a program is exemplified in the policies of the Bolsheviks (See BOLSHEVIK) in the period leading to and including the revolution of November 1917, in the subsequent developments of the Soviet Union under Communist leadership, and to some extent in the activities of the Communist parties of other countries. The Communist program has undergone many changes. The reason for such changes was stated in 1939 by Joseph Stalin (q.v.): «We have no right to expect of the classical Marxist writers, separated as they were from our day by a period of forty-five or fifty-five years, that they should have foreseen each and every zigzag of history in the distant future in every separate country.» Communists in the Soviet Union and elsewhere have explained their frequent changes of policy on the ground that the Communist program must from its very nature remain flexible, conforming to local conditions (as in China) and to changing world conditions.

Before the Russian Revolution it had been expected that the transition to socialism would be effected through the medium of a parliamentary republic. One of the outstanding innovations of the Bolsheviks, led by Lenin, was their decision to recognize the soviets (See SOVIET)—councils of industrial workers and soldiers—as the most efficient vehicle for the seizure and exercise of proletarian power. After the transfer of power to the proletariat, Communist leaders found it necessary to make many further modifications in Communist theory and practice, including especially those changes incidental to the building of socialism in a single country, in a world of hostile powers which were soon attacking the Soviet Union from every direction. Another such change was the temporary revival of private trading, introduced in 1921 under the New Economic Policy as a strategic retreat from the rigors of war communism. This move confirmed the wavering allegiance of the peasants to the Soviet regime, without which its success would have been impossible.

Meanwhile, under the Communist program a series of crucial decrees, some of them passed on the day following the seizure of power—were put into operation. These included—in addition to the decree establishing the first Soviet government, the decree calling for the restoration of peace, those replacing private with public ownership of land, forests and waters (and transferring over 400,000,000 acres of land to the peasants), those abolishing existing legal privileges based on wealth, nationality or religion, separating the church from the state and secularizing the schools, establishing legal equality of the sexes and of the various nationalities within the Union, and nationalizing all large industrial and commercial enterprises. These laws, and others necessary for the building of a socialist state, were followed by far-reaching economic changes. The New Economic Policy was discontinued. A vast program of socialist industry and electrification was launched. The struggle for the collectivization of agriculture

[2] Engels, op. cit., p. 139.

was begun, and the three Five-Year plans were successively put in operation.

Each of these major developments in the Communist program in the Soviet Union was attended by prolonged and intense discussion within the Communist Party. The decisions were finally arrived at in the face of persistent opposition, both from the Right and from the Left. The Right opposition was by those who would have wished to continue and extend the New Economic Policy into a general compromise with capitalism. The Left opposition was by those who condemned as a betrayal of the Revolution the decision to concentrate on the building of socialism in one country. The prolonged fight against these deviations, Communist spokesmen insist, was not a mere suppression of minority opinion, or a struggle for power between personal rivals. Culminating as it did in the great trials of 1937 and 1938, it was part of the general struggle to build the socialist state, and to protect it from enemies within and without who had been planning its destruction.

A report delivered by Joseph Stalin to the 18th Congress of the Russian Communist Party in March 1939 was later published under the title: *From Socialism to Communism in the Soviet Union.* (See *Bibliography.*) In this report Stalin traced developments in the foreign relations and the domestic economy of the U.S.S.R. and showed how with the victory of the socialist economic system it had become possible to adopt the new constitution of 1936, with its confirmation and extension of many individual liberties and privileges. For the same reason it was now possible to concentrate on the task of raising the general level of material well-being and culture. The coercive power of the state, exerted through the Red Army and Navy, the punitive organs and the intelligence service, no longer had to be used *within* the state. Yet this coercive power had still to be carefully maintained, since the danger of foreign attack (this was in 1939) still remained. The report looked forward to further advances toward communism as plans for developing the socialist economy, with its accompanying cultural revolution, were brought to fruition. It implied that complete atrophy of the state's coercive powers, marking a closer approximation to communism, could be expected only if surrounding countries became socialist.

Developments subsequent to 1939 bearing on the foreign relations of the U.S.S.R. show further indications of the trend in the Soviet Union toward full communism as dealt with in Stalin's report. For example, Hitler had long pointed to the Comintern as proof that the Soviet Union was trying to foment socialist revolutions in other countries. The Comintern's dissolution on 22 May 1943 nullified one of the main Axis appeals for an anti-Bolshevik crusade. The move also signalized growing Soviet confidence in the strength of the socialist state and in the growth of democratic sentiment among the United Nations.

Soviet authorities identify the development of the Soviet Union toward complete communism not with increased material production alone but with the extension of wider scope to its citizens. Three government measures are especially indicative of this intention. Since 1936 guaranteed employment, rest and leisure, social security at state expense, and extended provisions for free education have been constitutional rights of every Soviet citizen. A major emphasis in the Third Five-Year Plan, interrupted by the German invasion, was placed on consumer goods and services. And by the decree of January 1944 the central power voluntarily relaxed its authority, permitting the various republics of the Union to set up their own commissariats of war and foreign affairs.

The Second World War, in which the Soviet Union under its Communist leadership played a crucial part, brought worldwide recognition of the strength of the Soviet armies and the efficiency and adaptability of the Soviet economy, which created these armies and sustained them despite enormous losses. The period was marked above all by the drawing together of the powers (including the Soviet Union) committed to the global struggle against fascism, and by the promise, which became evident in the conferences of 1943 and 1944, of their continued collaboration in the period to follow the war.

The Communist Program in Countries Other than the U.S.S.R.—In March 1919 under Bolshevik initiative the Third Communist International (See INTERNATIONAL)—the Comintern—was founded in Moscow. Its First Congress, composed of delegates from many countries of Europe and America and representatives from many others, issued a call to the peoples of all countries, urging them to carry on a struggle for the worldwide establishment of socialism. By 1922 Communist organizations of about 52 countries were represented at the annual congress—about the same number as that composing the League of Nations.

Apart from short-lived soviet regimes in Hungary and in Bavaria (both in 1919) and the rise of Communist influence in China, seriously begun in 1923 (see CHINA), the Communists remained in most countries a more or less stormy opposition to existing governments. Where they were not excluded from participation in politics they gained representation in some of the legislative bodies, becoming important in their number and influence in pre-Hitler Germany and in France under the Popular Front, promoted the growth of trade unions, organized the unemployed, and called for the end of remaining discrimination against racial and other minorities. With the rise of Mussolini and Hitler the Communists appealed for a united front of all democratic forces against fascism and against the trend toward a second world war to which they insisted the Fascist movement would lead.

While the Fascist dictators were taking one after another the aggressive steps which finally led to the war, the Soviet government, especially through Maxim Litvinov, its spokesman in the League of Nations, was urging that the non-Fascist powers join in a collective security program to prevent further Fascist aggression. On 30 September 1938 the Munich Conference, from which the Soviet Union was excluded, opened the way for the Nazi invasion of Czechoslovakia. The policy of collective security was not applied. Communists of all countries, along with anti-Fascists generally, voiced the fear that Hitler through his anti-Bolshevist crusade might involve the leading capitalist nations in a war against the Soviet Union, an event which almost happened at the time of the Soviet-

Finnish campaign (1939–40). Such a war, they declared, would inevitably be followed by a crushing attack by the Axis on the capitalist nations themselves, and by the worldwide destruction of democracy. In Hitler's attack on the U.S.S.R. on 22 June 1941 the Communists recognized the danger to the U.S.S.R. in which centered their chief hopes for social progress. They also saw in this event a new situation, revealing the anti-Fascist side of the war, and hailed the promise of Prime Minister Winston Churchill to aid the Soviet Union as evidence of a new hope for uniting the democracies against the Axis. In the drawing together of the United Nations, culminating in the great conferences of 1943, especially at Tehran, the Communists saw the necessary conditions established for the co-operation of all democratic forces in defeating the Axis and assuring a better life for all peoples in the postwar world. In the United States they declared themselves willing to co-operate in these tasks with all anti-Fascist elements, asserting their intention not to raise the issue of socialism in such ways as to disrupt the common effort to achieve the tasks under the system of private enterprise. The dissolution of the Comintern marked a general turn in the Communist program due to increasing consolidation of the world's democratic forces.

COMMUNITY CHRISTMAS TREE MOVEMENT. The Community Christmas Tree Movement, which was initiated in New York with festivities for the children at Madison Square, in 1912, has very rapidly developed in popularity. The tree is lit from Christmas Eve till the midnight of 31 December, when thousands of children welcome in the New Year with music. Even before 1912, at San Francisco, the public singing of carols led by Madame Schumann-Heink and other distinguished artists was an eagerly watched event. Other cities all over the land have promoted the Christmas tree celebrations. The American Pageant Association Bulletin 41, 15 Oct. 1916, entitled «Some Suggestions for Community Christmas Celebrations,» gives lists of Christmas mysteries and plays and music with much other valuable information. Bulletin No. 42, 15 Nov. 1916, «The Possibilities of the Christmas Masque,» by William Chauncey Langdon, should also be consulted.

COMMUNITY DRAMA, or **CIVIC DRAMA.** This is a term that has recently sprung into widespread use to embrace various kinds of performances, generally more or less dramatic in form, but sometimes merely processional and picturesque, presented by large bodies of people (marching, singing, dancing, acting and so forth) in co-operation with writers, designers and others. The differences in kind are denoted by the use of the names: pageant, masque, festival; and, somewhat loosely, the rural play, the school play and the outdoor play. Mr. William Chauncey Langdon, the well-known pageant master, has cleared away much of the difficulty of classification by pointing out that the essential characteristics of these forms may be differentiated as follows: The pageant is historical; the masque is philosophical; the outdoor drama like the regular drama is individual; and all these are objective in their character. On the other hand, while the festival is lyrical, it is subjective in character. The school play is educational and subjective. These forms are all treated separately under special headings.

The history of the community festival, all that may be written with reasonable certainty, covers the long stretches of the past, under many a ritual, back to the immemorial religious cults. There can be little doubt that all theatres had their rude beginnings when human beings first began to dwell together in communities, and to hunt, feast, play and worship in common. For a fuller account of the primitive drama consult Grosse, E., 'Beginnings of Art,' and Frazer, J. G., 'The Golden Bough.' Mr. L. Havemeyer's 'The Drama of Savage Peoples' (Yale 1916) contains the new material in accessible form. The first chapter of Prof. Brander Matthews' 'Development of the Drama' gives an excellent summary of the broad facts.

The archetype of the Greek theatre itself, the apex and crown of all primæval culture, may be seen in active existence at the present day in the islands of Melanesia. There, in the rustic dancing circle, we have a perfect example of the Greek orchestra, *in embryo;* and in the little robing hut of these simple islanders of the south seas we are in at the birth of the magnificent Skene of the theatre of Athens; the word *skene* originally meaning a booth or tent, and then a stage, projecting our English word scene. These two extreme cases of the Greek theatre and the Melanesian circle provide us with exemplars of sites as suitable to-day as ever for either the community drama or festival.

In mediæval times, when first the Church and later the guilds and schools encouraged and assisted in the performances of the mystery and morality plays, all that existed by way of a theatre was distinctly communal. The passion plays, still performed in Oberammergau, Bavaria, and in Selsach, Switzerland, and elsewhere, are survivals of the mysteries and miracles of the old communities. In the spreading liturgy of the mediæval Church we mark the beginnings of the long slow rise toward the compact drama of the most modern playwright. Following the ecclesiastical period of play-making and play-going and entering upon the secu-

lar period of folk drama, the culmination was reached in the works of members of the trade guilds, of whom the wise old cobbler Hans Sachs (1494–1576), and merry John Heywood (1497–1590), are the classic types. Thereafter came the development of the regular theatre and the narrowing down of the expression of the dramatic instinct of the folk to the usual calendar festivals, games, etc., described with droll particularity in such compilations as Chambers' 'Book of Days.' In the 19th century, with the growth of machinery and the new industrialism, when men discussed the humanities more than they practised humanity, men and women and children, too, well-nigh forgot even these simple festive joys of the open air. They, however, remained in literature and in tradition for a new and more democratic practice in this present century.

"The civic theatre idea, as a distinctive issue, implies the conscious awakening of a people to self-government in the activities of its leisure. To this end, organization of the arts of the theatre, participation by the people in these arts (not mere spectatorship), a new resulting technique, leadership by means of a permanent staff of artists (not of merchants in art), elimination of private profit by endowment and public support, dedication in service to the whole community; these are chief among its essentials, and these imply a new and nobler scope for the art of the theatre itself." Mr. Percy Mackaye, author of 'The Civic Theatre' from which the above lines are taken, deplores the severance of joy from labor under modern commercial conditions, and conceives the one answer to the workers' protests to be in "Art, the recreative labor of leisure." His favorite phrase, his slogan and the subtitle of his book is, "the redemption of leisure." To the now swiftly increasing body represented by Mr. Mackaye the reorganization of leisure is not alone a fine aim in itself, but the real goal, the focus, of all the striving of the age, the fulfilment of the deepest instinct of humanity, the need for happiness. In the spirit of his illustrious British prototype, William Morris, he pleads for a theatre endowed as the public schools, universities, churches and libraries are already endowed.

On the other hand, the opponents of the community festival movement, while acknowledging the fine disinterestedness of its leaders, do not recognize any pulsing life in the pageantry of to-day, so far as it relates to America; they deny real interest on the part of the people, and maintain that we have no traditions upon which to found a vital community theatre comparable to the same in Europe. For an able expression of this view, consult "Modern Pageants not Spontaneous" (in 'The Nation,' Vol. XCV, p. 245, New York 1912).

The supporters meet these disavowals by reminders of our native Indian, Spanish, French, Colonial and Post-Revolutionary lore, and partly admitting a tincture of artificiality and crudeness incidental to the early stages of the cultivation of the form, point to the amazing growth of the movement among all classes over all the States. Particularly have they sought and found expansion, where alone vitality can be reached in any concern touching the genius of the mass, in the co-operation of the industrial and rural folk, as well as in that of the children. In point of fact no country or district in Europe, or any other part of the world, can show wider or more enthusiastic interest in community drama, especially on the part of the young people and educationists of all grades, than has been demonstrated by the United States. Indeed, in this form of the drama, and in this alone, can the United States show herself more forward than Europe. This holds good not only in respect to organization and scope but also to actual performance. See College Dramatics; Children's Theatres; Festival; Masques; Outdoor Theatres; Pageant; Rural and Folk Theatres.

Hone, London 1833; standard work).

Duncan Macdougall.

COMMUNITY MUSIC, a term recently brought into wide currency through the characteristic interests of the day along lines of social administration; and, in general, somewhat loosely embracing both old and new forms of organized musical practice. More strictly, however, it describes the newer, popular expressions of the love of music by way of recreational, ameliorative and educational settlements, as well as through countless neighborhood and municipal centres, both rural and urban, that have had their origin in the peculiar industrial, social and political conditions of recent times; many of these organizations corresponding to the more spontaneous outgrowths of merrymaking in olden days. See Festivals.

In the social consciousness of our day music has come to be regarded as a tremendous force in the well-being of the community,— recreational, educational, moral and spiritual,— whether the people be viewed in their capacity of listeners or performers. Loving the songs

and simple melodies they know well, the people are also moved intensely by even the difficult and unfamiliar classics, provided they are played with feeling and intelligence. «Great music greatly performed,» says Professor Dykema, «is able to overleap seemingly impossible barriers of lack of culture; the majestic strains of a Beethoven symphony played by a fine orchestra carrying every listener before them.» Then, much more intense is the influence of music in the case of the active performer, however humble. «In concerted music the social side is carried to its highest point. There are few social forces comparable to the power of a large group of people singing a grand chorus.» The continually rising standards of municipal concerts, the organization of community choruses, Christmas Tree celebrations, pageants and masques with music, school and community orchestras and popular symphony concerts all over the Western World, point to the general hunger for musical expression, more especially in the community sense.

This community movement, many-sided by its inherent nature and unfailingly democratic, sweeping over the greater part of the world, has had a most remarkable success in the United States. Its main sources of influence, both old and new, amateur and professional, are in (1) domestic and industrial circles; (2) schools and colleges; (3) churches; (4) specific musical organizations; (5) places of amusement; and (6) various musical activities; the notes of special interest being gathered under these headings, as follows:

Domestic and Industrial Circles.— No one can fail to make observation of the almost universal distribution of various modern mechanical inventions for the rendering of both instrumental and vocal music; the pianolas, phonographs, etc.— which, while retarding individual technical development in some circles, have in others encouraged group singing and playing to a point of enthusiasm and excellence in districts where the greatest performers of the day would otherwise, in all probability, have remained unheard. This applies most pointedly to a legion of large and small communities of factory, shop, studio, agricultural and other workers, who, till the advent of these new mechanisms, were often musically stranded, both in town and in country, to an extent that is only now being realized. Innumerable industrial groups have from such beginnings organized themselves until their trained bands, choirs, etc., have become of wide importance in musical affairs. Nevertheless it is regrettable that the antique custom of both solo and concerted singing at actual labor has well-nigh passed into oblivion in the greater part of both hemispheres. In America our own aboriginal people, the Indians, to whom song is the very consecration of the spirit of life, rarely undertake even the most menial tasks without an appropriate song. Like all real folk music, the music of the Indian is the spontaneous and most earnest expression of the soul of a people, and of all music the most distinctively American. Old tradition, tribal history, the counsels and warnings of every day, the mighty deeds and sayings of the wise and the brave, the unchallengeable verities, the call to worship and to the feast, all are expressed in the ritual of song and poetry.

Schools and Colleges.— Within the last decade a great change in musical instruction in the schools has resulted from the recognition by educationists throughout the country that music in the schools must be more than another type of disciplinary study; above all, in the insistence by the pedagogic leaders of the movement on the use of better musical material and a larger number of songs before beginning technical drill. They also point out the possibility of cultivating original art power among gifted pupils by allowing scope for individuality, and of developing the more conscious sympathetic aspects of the children's singing by allowing them to take part in musical festivals and concerts for the general community. In most of the larger communities throughout these States it has become customary to hear good music, ranging from simple unison songs, light operas and cantatas to the great oratorios creditably performed in the large auditoriums and parks by the children from the public schools. There are even orchestras and bands in some of the schools. These are able to assist at concerts with choruses of children; and churches, theatres, clubs and private individuals are seeking, and even competing against each other, to unite with the schools. Elgin, Ann Arbor and Dayton have already given remarkable offerings at low prices. Another step in advance has been made by the recognition by the schools of private instruction in music and by granting credit to pupils for work done outside. The public high schools, with the colleges and universities, are also allowing the courses taken with accredited music schools and private instructors to count for admission. A large number of high schools practise chorus singing and maintain musical appreciation classes; and certain of the more progressive offer instruction in the technique of music, in solo-singing and in instrumental work. In Richmond, Ind., for instance, the teacher of public school music was engaged on condition that he devote half time to municipal music. In Wisconsin there is a popular movement to create by law a city social centre where the musical and other recreations of the people may be more compactly and more intelligently controlled than under the present haphazard system, or lack of system. It has been proposed that community directors be appointed from among principals of high schools and officials of like standing, with a definite salary for each office.

Churches.— For a very large proportion of the adult population church music includes practically all the serious music which they are in the way of hearing, and carries the one complete opportunity for chorus singing. A number of churches, recognizing the fact, are dealing with the situation from its many points of view; and some are very wisely opening their doors to good secular work, in the lighter as well as the heavier vein,— operettas, pageants, etc. The American Guild of Organists has nobly responded to the call for wider activity. The church choir is in some districts doing much of the work formerly sustained only by the choral society; these choirs being found to have more influence upon the community than the work of the soloist. A number of churches, both in this country and abroad (as in «America's Musical Shrine» at Bethlehem, Pa., and at Worcester Cathedral, England, where fes-

tivals of music have been annual events for nearly 200 years), have generously cultivated the love of song and instrumental music.

Specific Organizations.— Early in the last quarter of the 18th century the Stoughton (Mass.) Musical Society, which still flourishes, was founded by William Billings, a tanner by trade, an eccentric and a music teacher of some genius. This energetic man gave a healthy impulse to popular music that is yet felt. About the same time the excellent Handel Society of New Hampshire was organized; and the year 1807 saw the foundation of the Massachusetts' Musical Society. On 8 Jan. 1792, at Medfield, Mass., the "father of music in America," Lowell Mason, was born. To him we owe our best ideas in the promotion of music among the masses. He pointed the way to a higher order in church music, introduced music into the public schools, popularized class chorus singing, spread the art of teaching music on the rational inductive plan and established teachers' conventions and institutes. He died in 1872. In various corners of New England musical festivals with large choruses and orchestras, formed from small choral societies of neighboring towns, are held regularly. Two typical instances of these are the concerts at Conobie Lake Park by a chorus of over 300 singers from four nearby towns,— Lowell and Lawrence, Mass., and Manchester and Nashua, N. H.,— under the direction of Eusebius G. Hood; and the Litchfield Country Choral Union at Norfolk, Conn. (originally, in 1897, the Norfolk Glee Club; and united with the Litchfield, Torrington and other local organizations in 1899, with a total membership, in 1914, of 677), conducted by Richmond P. Paine, and promoted and housed by the generosity of Mr. and Mrs. Carl Stoeckel.

Scattered widely over the country, a number of cities and towns of small size have lately come into prominence and have sometimes astonished critics of high standing with their general musical activity, and, particularly, with performances of the 'Messiah,' the 'Creation' and other classic oratorios. Two signal examples are to be found in Bethlehem, Pa., and in Lindsborg, Kan. At Bethlehem, by the admirable patience and perseverance of Mr. J. Wolle, extending over 30 years, a choir has been nursed up to so high a standard that its renditions of Bach are conceded to be the best of any of this kind in America. The annual festivals of our "Pennsylvania Oberammergau" have for years attracted the music lovers of this and other countries. At Lindsborg, a little town with a population of only 2,000, the Bethany Oratorio Society performs Handel's 'Messiah' with a chorus of 500 voices and an orchestra of 40 pieces, during each Easter week. The chorus is more than 30 years old and has given Handel's masterpiece nearly a hundred times; and has, besides, undertaken all the standard oratorios. During the Easter festival the population is increased threefold,— visitors pouring into the centre from far and near.

Places of Amusement.— While the American citizen is a generous spender on concerts and all other forms of musical activity, the status of musical taste and ability is generally admitted to need advancement. Audiences are characterized as being too good natured and too careless of standards. That the leaders of music in our numerous communities are creating a warmer and more spiritual understanding between themselves and their audiences is the most hopeful of all signs. Even in unexpected quarters the people have been shown invariably to follow a good lead. At the New York Rialto Theatre, a vaudeville and motion picture house, music of a high standard was lately tried with such success that the orchestra soon became the chief feature of the performances.

Possibilities in the Ordinary Community. — The signs on the horizon point to the responsibility for the development of community music being in the hands of city governments; though, as yet its progress has been due mainly to private enthusiasm and enterprise. In a number of communities professional musicians during prolonged visits unite the amateur talent of a neighborhood, and with a few imported players produce worthy musical festivals. The results at Meriden, N. H., in the Pageant of 1913, under the musical direction of Mr. Arthur Farwell, and in similar performances of the kind elsewhere, illustrate how well the folk of small country places may be inspired by an occasion to play music of a high grade most acceptably. (See PAGEANTS and COLLEGE DRAMATICS). And the possession of an excellent band or orchestra has proved a possibility for the most unpromising of communities. Most of the great orchestras in large cities are maintained through a guarantee fund by subscribing citizens on a private basis. In one State a bill has recently been passed for the support of a State orchestra that will have a complete and regular circuit. In a number of places throughout the country music, concerts and lectures for adults are part of the educational system. One community extends musical instruction to all who are willing to embrace the offer. In New York, Boston, Rochester and in La Porte, Ind., a special official has been appointed to supervise the city music. In New York three municipal concerts began in the spring of 1910 on a new untried basis under the administration of Mayor Gaynor. There were bands in about 30 of the 150 parks in the city on one evening of the week during summer. Sometimes bands performed on all recreation piers ev y evening for a season, and sometimes only on three evenings, with afternoon folk-dancing for the children on the piers. In Central Park the crowds were enormous; and at Tottenville, S. I., the farmers and others gathered round in their wagons to listen to the worlds' masterpieces played by an excellent local band that for the first time in 20 years had joined the professional ranks. In many other centres throughout the country bands and orchestras are engaged by the authorities to give free concerts to the people in summer and even in winter. In the State of Wisconsin, any city, town or village is now authorized and empowered to conduct public concerts in parks (to be paid for out of the park funds) and in various kinds of auditoriums (to be paid for in any way that the board, town council or other stated official may determine).

Citizens as Performers.— The highest spiritual point in community music would appear to have been reached in the extension of a welcome to everybody, trained and untrained,

to sing in chorus. The wisest heads in the movement rule that in every healthy community there should be opportunity for all people to sing as much as they wish, and that at least one combined function might be held, of an informal sort, and almost without direction. The success that has already attended the carrying out of this principle has been extraordinary. The supervisor of music in the Minneapolis city schools reports that in Anoka, with a population of 3,000, everybody was invited, everything was donated, and over 2,000 more than the whole population of the town arrived to sing 'Home, Sweet Home,' 'Come Thou Almighty King,' 'Suwanee River,' etc. Recently in Minneapolis Park, at a free concert with a chorus of children, no less than 15,000 people attended. But perhaps the most remarkable expression of this kind is found in the Community Chorus movement, an offshoot of the Music School Settlement of New York, that in a very short space of time has taken whole communities by storm. It is essentially democratic and includes all who would meet together for the joy of singing, without voice trials and without dues. Hundreds of community choruses have been formed, and reports of organization and inquiries are entering from every State in the Union. New York, Buffalo and the Oranges (N. J.) have community choruses of over 1,500. Kansas has over 30 community choruses, with the University of Kansas in support of the movement; Wisconsin is carrying out the community music idea in the broadest fashion and has a leader in the University of Wisconsin. Newspapers in New York and everywhere are devoting full columns to accounts of the movement and its affairs. In New York the Community Chorus has sung every week since its organization, 9 Jan. 1916. During the summer seasons its «sings» were held every Sunday afternoon in Central Park with thousands present. It gave the memorable «Song and Light» festival in Central Park, 13–14 Sept. 1916, with over 50,000 citizens taking part; and the effect was so overwhelming that its repetition was peremptorily demanded for the following evening. On 26 Dec. 1916 before an audience of 10,000 Handel's 'Messiah' was given with 1,000 voices (80 per cent of the performers never having heard the work before beginning rehearsals); and in the Hippodrome, 29 April 1917, an audience of 4,500 joined eagerly in the community singing under Mr. Barnhart's direction and responded enthusiastically to the inspiring addresses of Mr. John C. Freund, editor of *Musical America,* and the Hon. Cabot Ward, park commissioner of the city of New York; this performance like all the rest of the chorus being free to the public in every sense. Another spirited organization on somewhat similar but graded and slightly exclusive lines is the People's Choral Union of New York, with from 600 to 1,200 members creditably performing the great oratorios and large choral works, organized by Dr. Frank Damrosch. The «Frank Damrosch of Boston» is Mr. Samuel W. Cole, who, as early as 1897, conducted free choral classes for the people of Boston. In Chicago the «musical evenings,» instituted by Mr. Arnold Dresden of Chicago University, and promoted by the Women's Trade Union League, gained the hearty co-operation of the park commissioners and have proved eminently successful.

Beyond the large choral clubs there are the smaller organizations; such as the Frauenchor and Maennerchor of the German communities in the United States, and the various types of choirs in the communities of Wales and other countries. The enormous extent of musical activity possible in a community is indicated by the numerous competitive musical festivals of Europe. Blackpool, England, for example, has such a festival with about 5,000 competitors from all over England entering 64 types of contests, including choruses of 60 voices and all variations of fewer numbers for men or women or both men and women, down to solo.

In the United States the closest resemblance to such festivals is found in the Saengerfest and the Eisteddfod. At a recent Welsh celebration in Pittsburgh by Cambro-Americans the chief interest was music, although there were competitions in other arts. The choirs came from the mills, mines and factories for the most part. For Christmas and other festivals by various sorts of communities, see FESTIVALS.

Instrumental Music.— There are many nurseries of instrumental music scattered over the great cities of the world, but perhaps the most significant of them all is the Music School Settlement on the East Side of New York. In 1917 there were 1,100 enrolled pupils, as well as an «outside» department and a very long waiting list, with a staff of 100 teachers. There are four orchestras, aggregating 200 players, a wind instrument department, a musical bureau which secured over 300 paid engagements for pupils in 1916, a library of 2,500 readers, an instrument department with 100 instruments for the use of pupils, lectures, concerts, festivals and plays. There is a social centre in charge of a head resident and her assistants who manage the various clubs, etc., and help the music teachers in the effort to develop the children physically, mentally and morally. There are 15 nationalities represented; and the terms to pupils run from 50 cents for an individual lesson to 10 cents for a class lesson. A limited number of scholarships are provided for talented pupils who cannot pay these fees. The Maidstone movement in England is of the same type.

The National Union of School Orchestras, London, was founded in 1905, giving its first performance at the Crystal Palace with 700 girl and boy violinists, with such success that in 1914 the performance at the Crystal Palace was given by 6,800 children. But even these figures represent but a small fraction of violin-playing children over the kingdom; for with 5,000 schools having orchestras already formed there are at least 200,000 children who are members or adherents of the Union. There are scholarships which entitle the winners to advanced instruction at the Guildhall School of Music. The official mouthpiece of the organization is *The Young Musician,* published monthly in London for one penny. The various objects and interests of the National Union of School Orchestras, as well as many other important matters, are discussed by Mr. Paul Stoeving, 'A New Mission for the Violin' (in the Proceedings for 1915 of the Music Teachers' National Association, Hartford, Conn., 1915).

A curious and remarkably successful attempt to increase violin playing in Great Britain was made recently by a firm of musical instrument makers who distributed complete violin outfits for the moderate sum of $5. In a short time no fewer than 400,000 people had received instruments.

The Music Teachers' National Association with headquarters in Hartford, Conn., have a special committee for community music.

COMMUTATOR, a piece of apparatus used in connection with many electrical instruments for reversing the current from the battery. There are various forms, which will generally be found described with their proper instruments. See ELECTRICAL TERMS.

COMNENUS, or **COMNENI**, kŏm-nē'nē, an extinct family of Byzantine sovereigns, originally from Paphlagonia, which numbered, on the throne of Constantinople (1057 to 1204) and on that of Trebizond (from 1204 to 1461), 18 emperors, besides 19 kings and numerous independent princes. When the Crusaders had overturned the throne of the Comneni in Constantinople, and established the Latin empire there in 1204, a prince of the ancient house of the Comneni founded an independent state at Trebizond in Asia Minor, where he was governor. The last sovereign of this house was David Comnenus. From him, it is said, was descended Demetrius Comnenus, a French captain of dragoons, who died without children at Paris in 1821, with the title of *Maréchal de camp*. But his descent cannot be historically traced. Ducange asserts without hesitation that Mohammed II, the conqueror of Constantinople, after he had obtained the empire of Trebizond, so called (which was scarcely as large as a French department), from the Emperor David, by a treaty, sent for this prince and his seven children to Constantinople. In order to get possession of the income which had been secured to the Greek prince he ordered him to be put to death, with all his children, at Adrianople in 1462, under pretense of a conspiracy. This is confirmed, according to Ducange, by all contemporary writers—Chalcondylas, Ducas, Phranzes. A remarkable member of the family was the Princess Anna Comnena, daughter of the Emperor Alexius I, who flourished in the first half of the 12th century.

COMO, kō'mō (anciently COMUM), Italy, capital of the province of Como, in Lombardy, 24 miles northwest of Milan in a delightful valley at the foot of Lake Como. It is a bishop's see. The city contains some antiquities, a splendid marble cathedral dating from the 14th century and 12 beautiful churches; also a cabinet of natural history and natural philosophy. During the 11th and 12th centuries Como was at the head of the Ghibelline party, and the rival of Milan. In 1127 it was destroyed by the Milanese and rebuilt by Frederick I in 1159. Later it was ruled by the Rusca family and in 1335 came into the possession of the Visconti. In 1859 it was a centre of the agitation headed by Garibaldi. Here was born Pliny the Younger and Volta and Giovio, writers, also the popes Clement XIII and Innocent XI. A number of the inhabitants travel about with small-wares, such as mirrors, spectacles, little pictures. Even in the time of the Roman emperors this taste for emigration manifested itself. The inhabitants of Como were then to be found in all parts of Italy in the capacity of masons. Silk, velvet, optical glasses, shoes, stockings, metal work and knit wear are manufactured. The province of Como has an area of 798 square miles and a population of 481,000. It has fine pastures, and yields grain, olives, wine and silk. Population of the commune 48,366.

COMO, Lake (LAGO DI COMO, lä'gō dē kō'mo, anciently LACUS LARIUS), a lake in the north of Italy, at the foot of the Alps. Toward the middle it is divided into two branches by the point on which is situated Bellagio. The branch extending toward the southwest to the city of Como goes under the same name; that which turns to the southeast to Lecco takes the name of Lake Lecco. The length of the lake to Bellagio is 16 miles, that of the southwest branch 19 miles and that of the southeast branch 12½ miles. The greatest width is two and a half miles. More than 60 rivers and rivulets flow into it, and the Adda passes through it. It is about 700 feet above the level of the sea, and about 190 feet above Milan. Lake Como, the most delightful of all the lakes in Upper Italy, is surrounded by mountains 3,000 or 4,000, or even 7,000, feet high, which descend toward the lake, and in many parts are

clothed with woods. It is bordered by delightful gardens and country seats. Fish, particularly trout, are caught in the lake. The neighboring country is rich in minerals—iron, copper and lead.

COMO STAGE, a thin mass of shales and sandstones representing clays and sands deposited in a fresh-water lake that covered southern Wyoming and extended into Colorado. The exact age of the beds is still in dispute; they have been assigned to the top of the Jurassic, though there are good reasons for placing them at the base of the Cretaceous. The beds are remarkably rich in fossils of land reptiles and mammals, including such giant saurians as *Atlantosaurus,* and are typically developed near Como, Wyo. See CRETACEOUS SYSTEM; JURASSIC SERIES.

COMONFORT, Ygnacio, ĭg-nä-sē-o kō-mŏn-fōrt', Mexican general: b. Pueblo, 12 March 1812; d. 13 Nov. 1863. He became a captain of cavalry in 1832, in 1834 was made prefect and military governor of the district of Tlapa, and in 1842 he was elected member of the National Congress. This Congress was soon dissolved, and Comonfort resumed his functions in Tlapa, displaying great energy in repelling the aggressions of hostile Indians. Appointed 3d alcalde of the capital, and afterward prefect of western Mexico, he relinquished these positions to engage in the war with the United States; and on Santa Anna's dissolving the army and leaving the capital open for the Americans, Comonfort commenced organizing guerrillas, when he was summoned to the Congress of Queretaro, where a treaty of peace was concluded with the United States. He was now chosen senator by his native state, and served in this capacity until 1851. In 1852–53 he was the representative in Congress of the newly created state of Guerrero, and acted as custom-house director of Acapulco and other places until Santa Anna's return to power, when he was dismissed from office. He now joined Gen. Juan Alvarez, raised the standard of rebellion, proclaimed the plan of Ayutla, 11 March 1854, and compelled Santa Anna, who endeavored to seize that town, to retreat. At the end of the campaign in 1855, Santa Anna was finally compelled to abdicate. Alvarez assumed the supreme government, but shortly afterward delegated his authority to Comonfort, who became provisional President of Mexico, 11 Dec. 1855. He soon met, however, with the most strenuous opposition on the part of the clergy, the army and the large body of the Conservative party. The junta of Zacapoaxtla declared itself on 19 December against the President, and a little later the seat of revolution was transferred to the city of Pueblo. Over 5,000 men assembled there in February 1856. Comonfort marched against them, forced the rebels to surrender on 20 March, promulgated on 31 March a decree ordering the confiscation of the property of the Church, followed on 28 June by another decree forbidding the clergy to hold landed estate. At the same time he sent a Mexican envoy to Rome to settle with the Holy See the questions raised by these measures; but the Mexican clergy made all possible effort to prevent his reception, while at home they labored to undermine the government. Congress, which was opened by the President, 5 Feb. 1857, assembled under very inauspicious circumstances. It proceeded, however, to draw up a new constitution, which vested the legislative power and the control over religious and military affairs exclusively in Congress. The President, finding it impossible to meet the difficulties which agitated the country under such restrictions, was eventually constrained, on October 1857, to apply for extraordinary powers. These were granted by Congress on 4 November and he was proclaimed constitutional President on 1 December. His position, however, became more and more critical. Opposed by the clergy and the army, he found himself isolated, and could only depend upon the brigade of General Zuloaga, which was attached to him personally. By a pronunciamento at Tacubaya, 17 December, this brigade, too, declared itself against the new constitution, but appointed Comonfort chief of a new government. By a new pronunciamento, however, of 11 Jan. 1858, they discarded him altogether, and the insurrection which broke out on that day in the capital led to a fierce struggle of several days. Appointing Juarez, president of the Supreme Court, provisional President, Comonfort attempted to regain his authority by force of arms, but in vain. On the morning of 21 January the capital was in the hands of the rebels. The House of Representatives, convoked on the same day by Zuloaga, appointed that general provisional President, while Juarez convened a Congress at Guanajuato, to guard the rights of Comonfort. The latter in the meantime, deserted by his soldiers, and unable any longer to maintain his power, repaired to the United States. He returned in 1861 and was Minister of War in the Juarez cabinet. He was also appointed general of one of the armies of the Republican party, and for a time he held command of Zaragoza. He was sent to the relief of Puebla in 1863; but he was defeated by an Imperialistic force to which the city was afterward forced to surrender. Subsequently Comonfort was killed by a party of guerillas who shot him from ambush.

COMORIN. See CAPE COMORIN.

COMORO ISLANDS, a volcanic group in the Indian Ocean, between the northern extremity of Madagascar and the continent of Africa. They are four in number—Mayotte, Anjouan, Grande Comore and Moheli. France took possession of Mayotte in 1843, and made it a colony. The other islands came under her protection in 1886 by treaty, and by an act of 1912 and a decree of 1914 the whole group has become a colony, attached to the government of Madagascar. The islands are very fertile. Vanilla is the chief product, having in recent years supplanted sugar to a very great extent. Grande Comore has extensive forests. Imports: Cotton fabrics, metals and rice. Exports: Hides, sugar, copra and vanilla. The natives are professed Mohammedans. Area, 790 square miles. Pop. 119,305.

COMPANY (Old Fr. *companie,* from Latin *companirem,* "mess," from *com-,* "with," and *panis,* "bread"), an association of individuals formed for some purpose of mutual advantage, especially for business purposes. The commercial use of the word which bulks most largely now has two separate uses: in general of a firm or corporation; and particularly of the silent members of a business house whose

names do not appear in its style but are comprehended by the affix "and Company." Historically the earliest occurrence of the term in connection with business enterprise dates in England back to the 14th century when the Merchant Adventurers of England about 1359 began trade. English commerce and empire are equally indebted to the efforts of the companies formed in the early part of the 17th century. The Eastland Company, the Muscovy Company and the Turkey Company carried English trade into eastern Europe. The East India Company won the major part of the Asiatic trade for England, and gained possession of India and administered that country until the middle of the 19th century. The Virginia Company and the Massachusetts Bay Company prepared the way for English colonization in America, but never flourished. The history of the Hudson Bay Company is another interesting episode because of the combination of territorial and trading grants which it long held and because it still enjoys trading privileges. England still employs the same method of opening up trade, and the North Borneo Company, the British East Africa Company and the famous South Africa Company were formed between 1880 and 1890. Germany under her imperial policy fostered the formation of such associations, and in 1884 the German East Africa Company was started, with the object of extending trade and colonization. The London City companies also are historically important as outgrowths of the mediæval guilds and because for many years membership in them was a necessary preliminary to political privilege of any sort; their authority was curtailed in 1725 and by the reform bills of the 19th century, but members of the companies are still the only electors for civic offices.

In modern commerce companies may be most conveniently divided into the simple firm or partnership, which is a mere mutual agreement, and the stock company, which, by reason of its complex character and quasi-public nature, comes under State control and has displaced to a great degree the simpler method. In the stock company, instead of a private agreement, the members, under State authorization, make a company with a fixed capitalization divided into a certain number of shares, possession of which carries the right to vote, proportionally to holdings, on matters of business policy. State regulations require in all cases that one of the contracting parties be a resident of the State in which the company is incorporated, and that an office of the concern be located in the State. Other requirements vary in different States, especially in the matter of fees, which some of the western States have reduced to a minimum for the sake of attracting business to the State, and replenishing its treasury; and in the breadth and range of powers granted by the charter. The corporation laws of the State of New Jersey, together with its convenient situation near New York, have drawn a tremendous volume of this business to it. See CORPORATION; TRUSTS.

A particularly American class of stock company is the industrial, which is especially adapted to mine-exploiting or the development of agricultural business. In mode of government it differs from the usual shareholder controlled company, as it is largely managed by a promoter. (See JOINT-STOCK BANKS; PARTNERSHIP). Consult Anderson, 'Origin of English Commerce'; Cawston and Keane, 'Early Chartered Companies'; Cunningham, 'Growth of English Industry and Commerce'; Davis, 'Corporations: Their Origin and Development' (New York 1905); Bonassieux, 'Les grandes compagnies de commerce' (Paris 1892); Ditchfield, 'The City Companies of London and their Good Work' (London 1904); Unwin, 'Industrial Organizations in the Sixteenth and Seventeenth Centuries' (Oxford 1904); id., 'The Guilds and Companies of London' (London 1908).

COMPANY, in military nomenclature regularly designates an integral part of a regiment or battalion and consists of 100 men. A looser and typically American use of the word applies it to any small body of soldiers or uniformed men, especially as independent of a State or national soldiery. These independent companies form a valuable supplement to army and State militia, as was evidenced by their service in the Spanish War. See ARMY ORGANIZATION; TACTICS.

COMPARATIVE LITERATURE. See LITERATURE, COMPARATIVE.

COMPARATIVE PHILOLOGY. See LANGUAGE, SCIENCE OF.

COMPARATIVE PSYCHOLOGY. Animal psychology, comparative psychology and genetic psychology should be defined together and by contrast, first, because they are intimately related, and second, because there is serious disagreement between popular or current usage and strictly technical usage. Briefly, animal psychology designates certain materials of observation; comparative psychology, a particular scientific method of procedure; and genetic psychology a particular aim, goal or purpose, namely, genetic or historical description of mind. These statements may be somewhat expanded as follows.

Animal psychology actually means, in common usage, the study of mind in animals exclusive of man. Logically, it should mean the study of mind in animals (including man) as contrasted with plants, for there appears adequate ground for assuming that mind exists in plants.

Comparative psychology has long been used as practically synonymous with animal psychology, that is, as the study of infrahuman animals. Logically, and by analogy with other sciences, it should mean the application of the method of comparison to the phenomena of mind wherever and however presented for observation. Its meaning in terms of purpose and method should be the same as that of comparative anatomy, comparative physiology, comparative philology or comparative literature, namely, the more nearly complete and more profitable knowledge and understanding of a group of facts by comparison thereof with more or less closely related facts. The problems of origins and of developmental relations must ever be prominent in a comparative science. Secondly, the comparative method contributes directly and importantly to genetic description.

Genetic psychology is the study of the evolution of mind (phylogenesis of mind) in plants and animals and of the development or growth

of mind (ontogenesis of mind) in individuals. This branch of psychology is definable solely in terms of its primary purpose or aim, which is genetic description. Indeed, genetic psychology is simply the historical aspect of the study of mental life. Animal psychology, as also plant psychology, child psychology, abnormal psychology and social psychology, should contribute facts to genetic psychology, and comparative psychology should supply special methodological assistance. But genetic psychology as a special aspect of the general science should be restricted to no particular group of mental facts, to no single method. Instead, it should command all materials and all methods in the interests of a description of the processes of mental development and mental evolution. See ANIMAL PSYCHOLOGY; GENETIC PSYCHOLOGY; PSYCHOLOGY.

ROBERT M. YERKES,
Professor of Psychobiology, Institute of Human Relations, Yale University.

COMPARETTI, kom'pä-ret'tē, **Domenico Pietro Antonio,** Italian philologist: b. Rome 1835. At first he gave his attention to mathematics and natural science. Afterward he studied Greek by himself and in 1859 was appointed professor of Greek at the University of Pisa. He soon after removed to Florence and thence to Rome where he lectured on Greek antiquities at the university and studied the excavations in the Forum. He is also eminent in Romance philology and in the social history of the Middle Ages. After 1884 he edited the *Museo italiano di antichità classica.* His more important works are 'Saggi dei dialetti greci dell' Italia meridionale' (1866); 'Virgilio nel medio evo' (1872; Eng. trans., 1899); 'Papiro ercolanese' (1875); 'La commissione omerica di Pisistrato e il ciclo epico' (1881); 'Iscrizione arcaica del foro Romano' (1900). With D'Ancona he edited 'Conti e racconti del popolo italiano' (9 vols., 1870–91); and was also one of the editors of *Rivista di filologia e d'istruzione classica.* Died, Florence, 20 Jan. 1927.

COMPARISON, in grammar, the variation of an adjective or adverb used to express a higher and the highest degree, or a lower and the lowest degree of what is denoted by the word, thus modified in its grammatical form. The positive can scarcely be considered as a degree, as it denotes the quality generally without comparison. The comparative compares two things only, the superlative compares one thing with any number of others. In English the comparative is generally formed by the addition of *er,* the superlative by the addition of *est,* to the positive or monosyllabic adjectives and dissyllabic adjectives ending in *y,* or by the use of the words *more* and *most, less* and *least,* when the adjective is of more than one syllable and does not end in *y.* Adverbs are nearly always compared by the latter method. There are some adjectives, such as *good, better, best; little, less, least,* that do not form their degrees of comparison in the regular manner.

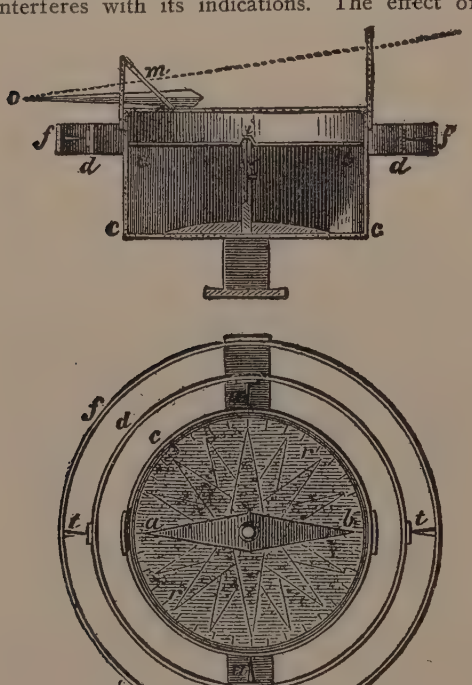
COMPASS, Mariner's, an instrument to ascertain directions at sea by means of the attraction of the earth for a movable magnet or a set of magnets. Similar instruments consisting of a magnetized needle resting on a pivot are used by the soldier or woodsman to determine directions on land. In the mariner's compass a thin circular sheet of mica is supported so as to turn with great freedom in a horizontal plane about its centre. This is called the compass-card. The bearing usually consists of a small plate of agate let into the card, and has a conical hole at the centre, and this rests on a fine needle-point of hard steel. This arrangement gives very little friction. To the under surface of the compass-card several parallel magnets are attached. Many experiments have been made to find the best arrangement for the magnets, but there is probably still something to be learned on this question, though the scheme patented by Lord Kelvin, in which the needles are suspended from the card in such a way that the moment of inertia of the card about every diameter shall be the same, is the most generally used. The compass-card is marked with a star of 32 rays, which are called the rhumbs, or the points of the compass. A line joining two of these points diametrically opposite is or ought to be exactly parallel with the magnetic axis of the arrangement below; and at the extremities of these points are

Compass Card

marked N. (north) and S. (south). E. (east) and W. (west) are marked at the extremities of another diametral line at right angles to the first. The other points have also names; and to repeat these from memory in order, beginning at north and going round the whole circle, is what sailors call "boxing the compass." Most compasses are also graduated in degrees, either separately in each quadrant from north and south, or from 0° to 360° from north in a clockwise direction.

The card is supported, as we have said, on a steel point, which is attached either to a hemispherical bowl of thick copper, or to a thick copper ring when the compass is to be used for night-sailing in which case a lamp placed below the ring shines up through the mica card and makes the markings on it visible. This thick copper bowl or ring is called the compass-box. Its use is to damp the vibrations of the needle; for it is found that the presence of a large mass of copper properly placed damps the vibrations of a freely suspended magnet rapidly, while it does not at all prevent it from coming to rest in the proper position. In certain forms

of compass, part of the weight of the card is borne by a non-freezing liquid, which also serves to damp its oscillations. The compass-box is suspended on gimbals, which are two concentric copper rings. The larger turns on a horizontal axis, whose extremities rest on the inside of the case that contains the compass. The smaller ring turns on a horizontal axis at right angles to the former, and resting on the outer ring. The compass-box is attached to the inner ring, and its weight tends to keep both horizontal. Thus supported, the compass-box and card always remains horizontal however the ship rolls or pitches. The chief difficulty in making use of the compass arises from the magnetism of the ship itself. In iron ships particularly, the magnetism of the ship greatly interferes with its indications. The effect of



Ship's Compass

a b, Needle. *c c*, Box. *d d*, Inner gimbal. *f f*, Outer gimbal. *i*, Pivot upon which the card is placed. *m*, Reflector. *r r*, Card. *t t*, *u u*, Supporting pivots.

the ship's magnetism is determined by swinging the ship, and determining a correction to be applied for every position. This, however, is liable to some uncertainty, for it is found that rough weather and other circumstances alter the magnetism of the ship, and therefore its effect on the compass. It is usual to place a compass at the mast-head of large ships, and from time to time to compare the deck compass with it. Furthermore, the inherent magnetism of the ship is compensated for to a great degree by an extremely complicated arrangement of bars of soft iron and magnets placed in the binnacle.

The origin of this instrument cannot be traced with anything like certainty. It has been supposed that the Chinese knew something about the polaric property of loadstone more than 2,000 years before the Christian era. In the 12th century the compass became known in Europe. Whether it was learned from the Orient is not certain. The Italians ascribe the invention of the compass to Flavio Gioja, a native of Amalfi, giving the dates 1300–20, but it has been shown that he can be credited only with some important improvement of the instrument. The discovery of the variation of the needle has been generally attributed to Columbus, but is now supposed to have been known much earlier. See GYRO-COMPASS; MAGNETISM.

COMPASS PLANT (*Silphium laciniatum*), a tall composite yellow-flowered plant growing on the prairies of the Mississippi Valley, and remarkable from the fact that its erect radical leaves stand so that their edges point almost exactly north and south, especially in midsummer. This is said to be due to the action of light, and to depend on the leaves having an equal number of stomata on either face. The plant is known in some localities as "resinweed," because it contains such a large amount of resinous matter. A European species of lettuce (*Lactuca scariola*) has received the same name.

COMPASSES, mathematical instruments used for describing circles, measuring lines, etc. They consist simply of two pointed legs movable on a point or pivot. For describing circles the lower end of one of the legs is removed and its place supplied by a holder for a pencil or pen. Hair compasses have a spring tending to keep the legs apart, and a finely threaded screw by which the spring can be compressed or relaxed with the utmost nicety, and the distance of the legs regulated to a hair's-breadth. Bow compasses have the legs united by a bow passing through one of them, the distance between them being adjusted by means of a screw and nut. Proportional compasses, used for reducing or enlarging drawings, have the legs crossing so as to present a pair on each side of a common pivot. By means of a slit in the legs, and the movable pivot the relative distances between the points at the respective ends may be adjusted at pleasure in the required proportion. Beam compasses are used where greater lengths are needed than can be secured by the ordinary pivot compasses. Points are arranged on a sliding bar so they can be clamped at certain distances from each other. Triangular compasses, having three legs, are used when it is desired to transfer the vertices of a triangle. Club compasses, or bullet compasses, are constructed with a ball instead of one of the points of the ordinary compasses; the ball being arranged so as to turn in a hole or socket.

COMPENSATION, that which is given or received as an equivalent for services rendered, losses sustained, sufferings endured or in pay-

ment of a debt; amends, remuneration, payment, recompense. When one is sued for a debt, it is competent for him, partially or wholly, to bar the claim by alleging that he is the plaintiff's creditor for services rendered or money lent. If the sum claimed from the plaintiff is found to be the exact equivalent of that for which he sues, the two are held to compensate or balance each other; if, on the contrary, it be less, it diminishes by so much the prosecutor's claim. If, however, the defendant feels that he owes the plaintiff more than that individual is indebted to him, he is required at the outset to pay into court the smaller sum for which he admits himself to be responsible.

Compensatio injuriarum is a defense against actions for damages claimed for slander, false accusations and like causes.

COMPENSATION, Workmen's. See Accidents, Causes and Preventions of; Workmen's Compensation.

COMPENSATION BALANCE, or **PENDULUM,** a balance-wheel or pendulum for a watch or chronometer, so constructed as to make isochronal (equal time) beats, notwithstanding changes of temperature. This effect is usually attained by having the balance-wheel cut into two segments, the arcs being fixed at one end each. This allows space for the expansion and contraction to counteract the varying strength of the spring. A compensation pendulum is generally what is known as a mercurial pendulum or a gridiron pendulum. It is constructed of two different metals, such as brass and iron, which so work against each other, that the expansion of the one downward is counteracted by that of the other upward. By this arrangement the pendulum does not vary in length, and consequently, in frequency of vibration, whatever the temperature may be. Arnold's compensation balance-wheel for chronometers and watches is constructed on a similar principle. See Chronometer.

COMPENSATION INSURANCE. See Workmen's Compensation.

COMPENSATION PENDULUM. See Compensation Balance.

COMPETITION, a term nearly equivalent to the phrase «struggle for existence.» Lamarck was the first to point out definitely the fact of competition in the cases of man and the sloth, but it was not until a half-century later that Darwin and Wallace emphasized its far-reaching importance as a biological agent in evolution. Competition may be most strikingly illustrated by a case in which it is entirely absent. The Great Salt Lake of Utah is inhabited by the brine shrimp (*Artemia fertilis*), which abounds in enormous numbers in the dense briny waters; hundreds may be dipped up in a dish of water and thousands captured by a few sweeps of the tow-net. As the water is so salt that no other animal can live in it except a maggot near shore, it has absolutely not an enemy, and there is no other form to compete with it. Its food is a floating green alga (*Polycystis packardii*). It is absolutely harmless and without means of defense, and lays but few eggs; yet its success in point of numbers is beyond all precedent. Another case is that of a fly (*Ephydra gracilis*) whose larva abounds at the margin of the same lake. These two cases illustrate how a species may abound in profusion, though not crowding out other forms, since there are no competitions.

A familiar example of the crowding out of native species by those introduced from foreign countries in the struggle for existence among plants is the ox-eye daisy, which was introduced from Europe, first appearing in Leicester, Mass., in 1740. Many years ago what were once throughout New England green fields of grass became white with its flowers; it drove out even the grasses introduced. On the other hand, in central Europe, throughout France, the Pyrenees and the Alps, as recently observed, it grows sparsely, never in extensive patches. Other examples are the introduced European injurious insects, the gipsy moth, the scale insects and many others, whose numbers in the Old World are kept within due limits by ichneumon parasites, but which in the United States and Canada, owing to the absence of their natural enemies, breed in unlimited numbers. Another case is that of the Colorado potato-beetle, which spread eastward from comparatively limited tracts in the Rocky Mountain region, and invaded the Eastern States to the shores of the Atlantic. The English sparrow, introduced during a period from 1850 to 1870, has become, owing to the lack of competition, a grievous pest, driving out the native birds. The periwinkle (*Littorina littorea*) of the European coast, introduced on our shores, about 1855, has multiplied to such an extent that it lives between tide-marks in millions, to one of our native species of the same genus. Such cases as these throw light upon the subject and prove that there is a silent but unceasing struggle for existence going on over nearly all the earth's surface. Yet in the case of desert plants which grow sparsely, separated by barren spaces, there is, as Henslow has observed, no struggle for existence.

Nowhere is the agency of competition more marked than in human society. In the lower savage races, as in the black race of Africa or the natives of Australia, the scattered tribes have confined their contests to simple raids, and no single people or sub-race has gained marked pre-eminence over another, with the exception of the Hottentots and Bushmen, who were largely exterminated by negro tribes from the North. But as we ascend to the higher or white race, to the Semitic, the western Asiatic and European peoples, we have examples of the sudden rise to power and pre-eminence of vast hordes of barbarian peoples under Tamerlane, the Grand Mogul, Attila and other conquerors, which have swept over vast territories and crushed the weaker, more peaceful or even civilized but less resistant nations. The rapidity with which the Arabs overran and still dominate northern Africa in language, social customs and religions; the Mongolian movements eastward into China, and westward to the borders of Europe; the successive rise and irresistible waves of migratory hordes from eastern to northern Europe, throughout prehistoric and historic times; the colonizing and expansion of the powers of Greece, of Rome, of the Norsemen, Anglo-Saxon, the Spanish, French and German peoples; the success of the white race in the struggle for pre-eminence; the disappearance of the lower, weaker races, less favored intellectually and morally, some of which

that point whose Cartesian co-ordinates are (x, y). The distance $\sqrt{x^2+y^2}$ of z from the point $z=0$ is called the *absolute value* of z and is written $|z|$. Let S denote a region of the plane bounded by one or more closed curves. To every point z of S let one or more numbers w, real or complex, be assigned according to some definite law. Then w is said to be a single- or multiple-valued *function* of z: $w=f(z)$. For the present we shall restrict ourselves to single-valued functions.

2. Continuity and Limits.— The function $w=f(z)$ is *continuous* in the region S if, when z describes any continuous curve in S, the image w of z describes a continuous curve in the w-plane. The variable $f(z)$ is said to *approach* b *as its limit*, if, when z approaches a along an arbitrary path, the corresponding point $w=f(z)$ approaches the point $w=b$; in symbols,

$$\lim_{z=a} f(z) = b.$$

A complex variable z is said to *become infinite:* $\lim z = \infty$, if its absolute value becomes infinite; i.e., if the corresponding point of the complex plane recedes indefinitely, no matter in what direction.

3. Derivative.— The function $w=f(z)$ has a *derivative*, $f'(z)$, if the quotient $\Delta w/\Delta z$ approaches a limit, when Δz approaches 0:

$$\lim_{\Delta z=0} \frac{f(z+\Delta z)-f(z)}{\Delta z} = f'(z) = D_z w.$$

When z is the independent variable,

$$dw = D_z w \Delta z;$$

and it is shown, as in the differential calculus, that

$$dz = \Delta z \text{ and } dw = D_z w\, dz,$$

the latter relation holding no matter what the independent variable may be. The general rules for differentiation apply here, e.g.,

$$d(U+V) = dU + dV, \text{ etc.}$$

Moreover, we have

$$\frac{d(z^n)}{dz} = nz^{n-1}, \quad n = \text{pos. integer.}$$

Hence it follows that all rational integral functions, i.e., polynomials in z, and all other rational functions of z, can be differentiated according to the same rules as reals.

Theorem: The necessary and sufficient condition that the function

$$w = u + vi = f(x+yi)$$

have a continuous derivative is that the real functions u and v of the real variables x and y have continuous first partial derivatives satisfying the *Cauchy-Riemann Differential Equations:*

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}, \quad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}. \tag{1}$$

The condition is necessary. For since we shall always get one and the same limit, no matter along what path Δz may approach 0, let Δz pass first only through real values: $\Delta z = \Delta x$; thus

$$\lim_{\Delta x=0} \frac{\Delta w}{\Delta x} = \frac{\partial w}{\partial x} = D_z w.$$

Secondly, let Δz be pure imaginary: $\Delta z = i\Delta y$; then

$$\lim_{\Delta y=0} \frac{\Delta w}{i\Delta y} = \frac{1}{i}\frac{\partial w}{\partial y} = D_z w.$$

Hence

$$\frac{\partial w}{\partial x} = \frac{1}{i}\frac{\partial w}{\partial y},$$

and it remains only to separate the real and the pure imaginary terms. We omit the proof of the sufficiency of the condition.

Two functions which satisfy relations (1) are called *conjugate functions.*

Example: Let

$$w = e^x(\cos y + i \sin y).$$

Then

$$\frac{\partial u}{\partial x} = e^x \cos y = \frac{\partial v}{\partial y},$$

$$\frac{\partial u}{\partial y} = -e^x \sin y = -\frac{\partial v}{\partial x}.$$

Hence w has a derivative, and furthermore

$$\frac{dw}{dz} = w.$$

A function which is single-valued throughout a region S and has a continuous derivative in S is said to be *analytic in S.* The terms *holomorphic, monogenic* and *synectic* are also sometimes used in this sense.

4. Conformal Mapping.— Given any two functions

$$u = \phi(x, y), \quad v = \psi(x, y), \tag{2}$$

we may interpret them geometrically as transforming the points of one plane into the points (u, v) of a second plane. Thus a region S of the first plane will be *mapped,* if certain further conditions are fulfilled, in a one-to-one manner and continuously on a region Σ of the (u, v)-plane. For example, let

$$u = x^2 - y^2, \quad v = 2xy.$$

Here the first quadrant of the (x, y)-plane is mapped on the upper half of the (u, v)-plane, the family of lines $u=$const. going over into the family of equilateral hyperbolas whose axes lie in the co-ordinate axes, and the family of lines

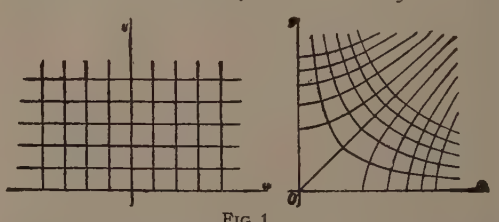

FIG 1.

$v=$const. going over into the orthogonal family, whose asymptotes are these axes.

If u and v have continuous first partial derivatives and if their Jacobian

$$J = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{vmatrix}$$

does not vanish then, at least for a restricted region S_0 about a point (x_0, y_0), the equations (2) will always define a one-to-one map of S_0 on a region Σ_0 including the point (u_0, v_0). This map will represent approximately (i.e., to infinitesimals of higher order than the first) a projection — in other words strain — of the immediate neighborhood of (x_0, y_0) on that of (u_0, v_0), a small circle about $(x_0 y_0)$ going approximately into an ellipse about (u_0, v_0). If, however, u and v are conjugate functions the ellipse be

comes a circle, and the angle under which two curves intersect in the (x, y)-plane is preserved in the (u, v)-plane. Thus the shapes of small figures are but slightly distorted. Such a map is called *conformal* or *isogonal*. The elements of corresponding infinitesimal arcs in the two planes are connected by the relation

$$dS = M ds,$$

where M is a positive function of x and y, and does not depend on ds, dS. The Jacobian here has the value

$$J = \left(\frac{\partial u}{\partial x}\right)^2 + \left(\frac{\partial v}{\partial x}\right)^2.$$

Referring to the developments of § 3 we see that the theorem just stated is coextensive with the following:

Theorem: If $w = f(z)$ is single-valued and analytic in the region S, then this function maps the neighborhood of any point z_0 of S, in which $f'(z_0) \neq 0$, in a one-to-one manner and conformally on the neighborhood of the point $w_0 = f(z_0)$.

The problem of conformal mapping first studied was that of making a map of the earth such that the shapes of small regions should be but slightly distorted. The two principal solutions that presented themselves were (*a*) *Ptolemy's Projection*, known in mathematics as *stereographic projection*, which consists in passing a variable ray through a fixed point of the sphere, which we will think of as the north pole. Let P and Q be respectively the variable intersections of this ray with the sphere and with the plane of the equator, or a parallel plane, taken as the plane of the projection. Then Q is the projection of P. (*b*) *Mercator's Chart.*

By a *simply connected region* is meant a region bounded by a single curve. Any simply connected region can be mapped in a one-to-one manner and conformally on the interior of a circle, and hence any two such regions can be mapped conformally on each other (Riemann, 1851).

5. The Elementary Functions.— (*a*) The Exponential Function. For real values of x the function e^x can be expanded by Taylor's Theorem into the series

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots$$

Substituting formally for x a pure imaginary value and operating with the infinite series as if it were a polynomial, we get

$$1 - \frac{y^2}{2!} + \frac{y^4}{4!} - \frac{y^6}{6!} \cdots + i\left(y - \frac{y^3}{3!} + \frac{y^5}{5!} - \frac{y^7}{7!} \cdots\right) = \cos y + i \sin y.$$

This formal work suggests a *definition* of e^x for a pure imaginary value of the argument, namely:

$$e^{yi} = \cos y + i \sin y, \qquad (3)$$

and it is this definition that we shall adopt, setting it at the same time more generally

$$e^z = e^{x+yi} = e^x(\cos y + i \sin y).$$

The function of e^z thus obtained is a true generalization of e^x, for it is single-valued and analytic for all values of z, reduces to e^x when z is real, and satisfies the same functional relations as e^x:

$$e^{z_1} e^{z_2} = e^{z_1 + z_2}, \quad \frac{de^z}{dz} = e^z.$$

(*b*) The Trigonometric Functions. When x is real, we have from (3)

$$\sin x = \frac{e^{xi} - e^{-xi}}{2i}, \quad \cos x = \frac{e^{xi} + e^{-xi}}{2}.$$

The right-hand sides of these equations have a meaning for complex values of the argument. By means of them we define the functions $\sin z$, $\cos z$:

$$\sin z = \frac{e^{zi} - e^{-zi}}{2i}, \quad \cos z = \frac{e^{zi} + e^{-zi}}{2}.$$

These generalized functions are single-valued and analytic for all values of z and satisfy the same functional relations as $\sin x$, $\cos x$; e.g.,

$$\sin(z_1 + z_2) = \sin z_1 \cos z_2 + \cos z_1 \sin z_2.$$

The $\tan z$ is defined as $\sin z / \cos z$, etc.

(*c*) The Inverse Functions. The function $\log z$ shall be defined as the inverse of the exponential function:

$$e^w = z, \quad w = \log z.$$

Setting $w = u + vi$, $z = r(\cos\phi + i \sin\phi)$, we have $e^u(\cos v + i \sin v) = r(\cos\phi + i \sin\phi)$.

Hence $$u = \log r, \quad v = \phi + 2k\pi, \text{ and}$$
$$\log z = \log|z| + (\phi + 2k\pi)i.$$

Thus it appears that the logarithm is no longer single-valued when complex numbers are admitted to consideration. For example,

$$\log 2 = .693\ldots + 2k\pi i.$$

In a similar way each of the other inverse functions is defined. We find

$$\cos^{-1} z = i \log(z + \sqrt{z^2 - 1}),$$
$$\tan^{-1} z = \frac{i}{2} \log \frac{i + z}{i - z}.$$

From the foregoing it appears that in the domain of complex quantities the trigonometric functions can be expressed in simple form in terms of the exponential function and conversely; while the inverse trigonometric functions express themselves in terms of the logarithm. Thus the formulas of integration:

$$\int \frac{dx}{a + bx^2} = \begin{cases} \dfrac{1}{\sqrt{ab}} \tan^{-1}\left(x\sqrt{\dfrac{b}{a}}\right), & ab > 0; \\ \dfrac{1}{2\sqrt{-ab}} \log \dfrac{\sqrt{a} + x\sqrt{-b}}{\sqrt{a} - x\sqrt{-b}}, & ab < 0, \end{cases}$$

apparently in no wise akin, are seen to be equivalent in the complex domain.

6. Laplace's Equation.—(*a*) Flow of Heat or Electricity. Let the points of the boundary of a homogeneous (or more properly isotropic) conducting substance be maintained at given temperatures (for example, a steam-pipe, the interior being kept at 100° and the exterior at 0°). Then a flow of heat ensues within the conductor and the temperature at any given point approaches a limiting value, u, as time goes on. In fact, if each point were brought to this limiting temperature, it would continue there so long as the boundary conditions are maintained and we should have a steady flow. The corresponding temperature u satisfies Laplace's Equation in three dimensions:

$$\Delta u = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0.$$

If in particular the solid be bounded by cylindrical surfaces whose elements are parallel to

the z-axis, and if the given temperature be constant along each element, then u will evidently be constant along any line parallel to the z-axis, and we shall have in substance a two-dimensional flow, for which

$$\Delta u \equiv \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0.$$

We may conceive the solid itself in which the flow takes place as two-dimensional if we think of a thin section as cut out of the above solid by two planes parallel to the (x, y)-plane and very near together. The flat faces of this slab are then to be thought of as coated with some adiabatic substance, so that no heat can enter or leave the slab across these faces.

The electrical problem is mathematically identical with the heat problem, u being interpreted as *potential* instead of temperature. As conductor consider for example a piece of tinfoil whose edge is connected with a thick piece of copper. Let one pole of a battery be attached to the copper and the other to the tinfoil at an interior point. We thus have a point source.

The curves u=const. are called *isothermals* or *equipotential curves*. The orthogonal trajectories of these curves v=const. are the *lines of flow*.

(*b*) Flow of an Incompressible Fluid. Consider the flow of an incompressible fluid constrained to move between two parallel planes, the particles which lie in any line perpendicular to the planes at any moment always remaining in that line. If there be a function u whose partial derivatives with regard to x and y give the components of the velocity of each particle of the fluid along the axes, then u is called the velocity potential. If u does not depend on t, we have a steady flow with velocity potential, and u here satisfies Laplace's Equation.

Conversely, let u be any *harmonic function*, i.e., a solution of Laplace's Equation, in two dimensions. Then this function defines a steady flow of heat, electricity, or an incompressible fluid with velocity potential.

Let us turn now to analytic functions of a complex variable:

$$w = u + vi = f(x + yi).$$

Differentiating the first of the equations (1) with regard to x, the second with regard to y, and adding, we see that u satisfies Laplace's Equation. Hence

Theorem: Every analytic function of a complex variable defines a steady flow of heat, electricity, or an incompressible fluid.

The converse is also true. Let us first recall the condition that

$$P\,dx + Q\,dy$$

be an exact differential, namely,

$$\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}.$$

If this condition is fulfilled throughout a finite region S, then

$$\int P\,dx + Q\,dy$$

taken over the complete boundary of S will vanish. Furthermore, if S has but a single boundary,

$$\int_{(a,\,b)}^{(x,\,y)} P\,dx + Q\,dy$$

will be a function of the upper limit (x, y) alone, not of the path of integration; cf. Goursat, 'Cours d'analyse,' Vol. I, § 152. It can now be shown that, given a steady flow of heat or electricity, a possible flow results if we interchange the equipotential lines and lines of flow.

Returning now to the main question, let u be any solution of Laplace's Equation, and form the function

$$v = \int_{(a,\,b)}^{(x,\,y)} -\frac{\partial u}{\partial y}\,dx + \frac{\partial u}{\partial x}\,dy + C.$$

Then the value of the integral will be independent of the path of integration,—at least if we confine ourselves to a finite region S with a single boundary. The derivatives of this function have the values

$$\frac{\partial v}{\partial x} = -\frac{\partial u}{\partial y}, \quad \frac{\partial v}{\partial y} = \frac{\partial u}{\partial x},$$

and thus satisfy (1). Hence u and v are conjugate functions, and $u+vi$ is an analytic function of $x+yi$.

The relation here pointed out between the theory of functions of a complex variable and certain problems of mathematical physics was employed by Riemann (1851–66) as a means of investigation in the former subject, and his method has been further developed by Klein (since 1881) and others.

7. **Cauchy's Theorem.**—Let $f(z)$ be single-valued and continuous throughout a region S, and let C be a curve lying in S. The integral of $f(z)$ taken along C is defined much as a curvilinear integral is in the calculus. Let C be divided by the points $z_0 = a, z_1, \ldots, z_n = b$ into n arcs; set $z_{K+1} - z_K = \Delta z_K$. Then if, as n increases, the lengths of all the arcs approach 0,

$$\lim_{n=\infty} \sum_{K=0}^{n-1} f(z_K)\Delta z_K = \int_a^b f(z)\,dz.$$

The following theorem, due to Cauchy (1825), is fundamental.

Cauchy's Integral Theorem. Let $f(z)$ be single-valued and continuous throughout a finite region S, inclusive of the boundary, and let $f(z)$ be analytic within S. Then the integral of $f(z)$, extended over the entire boundary C of S, has the value 0:

$$\int_C f(z)\,dz = 0.$$

Writing $f(z) = u + vi$, $z = x + yi$, we have

$$\int_C f(z)\,dz = \int_C (u\,dx - v\,dy) + i\int_C (v\,dx + u\,dy).$$

But each of these latter integrands is an exact differential (§ 6), since u and v are conjugate functions. Hence, by the theorem of § 6, each integral vanishes.

By means of this theorem many real definite integrals may be computed. In fact, it was through the attempt to obtain a rigorous deduc-

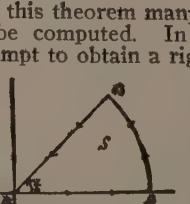

FIG. 2

tion of such formulas that Cauchy was led to his theorem (memoir of 1814). We will give one example: Consider the integral of e^{-Z^2}

extended along the boundary of the region indicated. Its value is 0. Hence

$$\left(\int_{OA}+\int_{AB}+\int_{BO}\right)f(z)dz=0.$$

Now let $OA=R$ increase without limit. The first integral thus becomes the well-known integral of the Theory of Probability:

$$\int_0^\infty e^{-x^2}dx=\frac{\sqrt{\pi}}{2}.$$

The second integral can readily be shown to approach the limit 0. In the third,

$$z=r(\cos 45^\circ+i\sin 45^\circ)=\frac{1}{\sqrt{2}}(1+i)r.$$

Hence

$$\frac{\sqrt{\pi}}{2}+\frac{1}{\sqrt{2}}(1+i)\int_\infty^0 e^{-r^2i}\,dr=0.$$

Setting $e^{-r^2i}=\cos r^2+i\sin r^2$ and separating reals and pure imaginaries, we obtain the evaluation of the Fresnel integrals:

$$\int_0^\infty \sin r^2dr=\int_0^\infty \cos r^2dr=\frac{1}{2}\sqrt{\frac{\pi}{2}}.$$

The *residuum* of a function $f(z)$ in a point a in whose neighborhood, with the exception of the point a itself, the function is single-valued and analytic, is defined as

$$\frac{1}{2\pi i}\int_C f(z)dz,$$

the path of integration C being a closed path surrounding the point a and containing no other singularity of the function. If $f(z)$ is single-valued and analytic in a finite region S except at a finite number of points lying within the region, then the sum of the residua of $f(z)$ at these points is given by

$$\frac{1}{2\pi i}\int_C f(z)dz,$$

where C refers to the boundary of S.

8. Development into a Taylor's Series.— In 1831 Cauchy extended Taylor's Theorem to functions of a complex variable and at the same

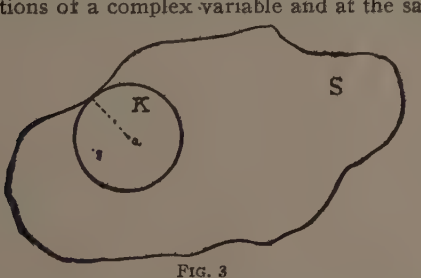

FIG. 3

time discovered a simple test for the range of values of the variable for which the series converges. Let $f(z)$ be single-valued and analytic in a region S, and let a be an interior point of S. Let K be the largest circle that can be drawn in S with a as centre so as to include in its interior no point of the boundary of S. Then, for all points z within this circle, $f(z)$ can be represented by the series

$$f(z)=c_0+c_1(z-a)+c_2(z-a)^2+\ldots,$$

where $$c_n=\frac{1}{2\pi i}\int_C\frac{f(t)dt}{(t-a)^{n+1}}=\frac{f^{(n)}(a)}{n!},$$

and $$|c_n|<Mr^{-n},$$

where M denotes the maximum value of $|f(z)|$ on the circumference of the circle $|z-a|=r$.

Example. Let $f(z)=(1-2\mu z+z^2)^{-\frac{1}{2}}$, where μ is a real constant numerically less than 1. Here either value of the function is continuous and analytic except where the radicand vanishes:

$$1-2\mu z+z^2=0,\quad z=\mu\pm i\sqrt{1-\mu^2},$$

i.e., at two points on the unit circle about $z=0$. Hence we can develop either value of the radical into a Taylor's series:

$$\frac{1}{\sqrt{1-2\mu z+z^2}}=P_0+P_1z+P_2z^2+\ldots,$$

where the coefficients P_n depend on μ alone, and the series will converge for all values of z within the unit circle.

The proof of the theorem is based on Cauchy's Integral Formula, by means of which the value of the function $f(z)$ at any interior point of S can be expressed solely in terms of the value of $f(z)$ along the boundary, C, of S:

$$f(z)=\frac{1}{2\pi i}\int_C\frac{f(t)dt}{t-z}.$$

This formula is deduced directly from Cauchy's Integral Theorem, and is analogous to the theorem in the Theory of the Potential by which the value of a harmonic function u at any point within a region is expressed in terms of its value $U(s)$ on the boundary, and of a function peculiar to the shape of the region, namely, the Green's Function G:

$$u=\frac{1}{2\pi}\int_C U\frac{\partial G}{\partial n}ds.$$

In fact, each formula can be deduced from the other one. The whole theory of functions of a complex variable can be based on Cauchy's Integral Formula as well as on the Taylor's development.

Conversely, let

$$c_0+c_1z+c_2z^2+\ldots \qquad (4)$$

be any power series converging for values of $z\neq 0$. Then it can be shown that this series converges within a certain circle of radius R and (excepting the special but important case that it converges for all values of z and thus represents a so-called *integral transcendental* function of z) diverges outside of the circle. Within this circle, called the *true circle of convergence*, the series represents an analytic function and forms in fact the Taylor's (or Maclaurin's) development of this function about the point $z=a=0$.

9. Other Series.— (*a*) Laurent's Series. If $f(z)$ is single-valued and analytic within a circular ring of radii r_1 and r_2 about the point a, then $f(z)$ can be developed into a Laurent's Series:

$$f(z)=\sum_{n=-\infty}^{\infty}c_n(z-a)^n,$$

convergent for all values of z within this ring: $r_1<|z-a|<r_2$. Here

$$c_n=\frac{1}{2\pi i}\int_C\frac{f(t)dt}{(t-a)^{n+1}},\quad |c_n|\leq Mr^{-n},$$

where C denotes a closed curve lying within the ring and encircling the point a, and M, r have the same meaning as in § 8.

(*b*) Lagrange's Series. Kepler's problem of developing a root w of the equation

$$w = a + z \sin w$$

(or more generally a function $\Phi(w)$ of this root) according to powers of z led Lagrange to formulate the following problem: To develop a root w of the equation

$$w = a + zf(w),$$

or more generally a function $\Phi(w)$ of this root, according to powers of z. He thus obtained the series that bears his name:

$$\Phi(w) = \Phi(a) + z\Phi'(a)f(a) + \sum_{n=2}^{\infty} \frac{z^n}{n!} \frac{d^{n-1}}{da^{n-1}} [\Phi'(a)f(a)^n].$$

Example: Let $f(w) = \frac{1}{2}(w^2 - 1)$,

$$w = \frac{1 - \sqrt{1 - 2az + z^2}}{z}.$$

Then $\partial w/\partial a = (1 - 2az + z^2)^{-\frac{1}{2}}$ and

$$\frac{1}{\sqrt{1 - 2az + z^2}} = 1 + \sum_{n=1}^{\infty} \frac{z^n}{n!} \frac{d^n}{da^n} \left[\frac{(a^2 - 1)^n}{2^n}\right].$$

Thus the form of the coefficients P_n in the example of § 8 is determined:

$$P_n(\mu) = \frac{1}{n!} \frac{d^n}{d\mu^n} \left[\frac{(\mu^2 - 1)^n}{2^n}\right].$$

These functions are known as Zonal Harmonics.

10. Roots and Singular Points.—A function $f(z)$ is said to have a *root* or *zero* at an interior point a of the region S of § 8 if $f(a) = 0$. It follows that $f(z)$ can then be written in the form

$$f(z) = (z - a)^m [c_m + c_{m+1}(z - a) + \ldots],$$

where m is a positive integer and $c_m \neq 0$ (unless $f(z) \equiv 0$). The point a is called a root or zero of *order* m; $f(z)$ is sometimes said to have m roots in $z = a$. A circle of definite radius can always be drawn about the point a containing no further root of $f(z)$.

If $f(z)$ is single-valued and analytic throughout the neighborhood of a point a with the exception of this point itself, and if $f(z)$ becomes infinite no matter how z approaches a, then a is called a *pole* of $f(z)$. Since $1/f(z)$ then has a zero in a, $f(z)$ can be written in the form

$$f(z) = \frac{\varphi(z)}{(z - a)^m},$$

where m is a positive integer and $\phi(z)$ remains finite and different from 0 at a; $f(z)$ is said to have a pole of *order* m, or to have m (simple) poles in $z = a$.

If, however, $f(z)$ does not approach a limit when z approaches a, and does not have a pole there either, a is called an *essential singularity*. In the neighborhood of such a point Weierstrass has shown that the function comes as near as one pleases to any arbitrary preassigned value.

11. Linear Transformations.— The linear transformation

$$Z = \frac{az + b}{cz + d}, \quad ad - bc \neq 0,$$

plays an important rôle in the theory of functions. If $c = 0$, we have an *integral linear transformation*. Interpreted geometrically as a transformation of the plane into itself, it comprises as special cases:

(*a*) $Z = z + b$, i.e., a translation;
(*b*) $Z = e^{ai}z$, " a rotation;
(*c*) $Z = Az$, $A > 0$, " a stretching.

The general integral linear transformation can be generated by a succession of these transformations.

If, however, $c \neq 0$, we need to consider one further transformation:

(*d*) $$Z = \frac{1}{z},$$

This corresponds to an inversion in the unit circle: $R = 1/r$, followed by a reflection in the axis of reals: $Y = -y$.

The general linear transformation carries circles over into circles, straight lines being regarded, as in the geometry of inversion, as circles with infinite radii. The infinite region of the plane is considered as a *point* (not, as in projective geometry, as a line), and this is the convention which it is desirable, for reasons that cannot be named here, to make in the theory of functions. We speak of *the point* $z = \infty$.—Cf. an article by F. N. Cole, 'Linear Functions of a Complex Variable,' *Annals of Math.*, Ser. 1, Vol. 5 (1890), p. 121.

12. Multiple-Valued Functions.— When in the definition of § 1 more than one value is assigned to each point of S, the first thing to be done is to group these values in such a way that they form several single-valued functions. Consider for example the function $\sqrt{z}$. Setting

$$w = Re^{\phi i}, \quad z = re^{\theta i},$$

we have

$$R = \sqrt{r}, \quad \phi = \tfrac{1}{2}\theta, \quad \tfrac{1}{2}\theta + \pi.$$

If now we sever the plane along a line running from $z = 0$ to $z = \infty$, say along the positive axis of reals, we can then spread out two single-valued functions each analytic in this region, namely,

$$w_1 = \sqrt{r}\, e^{\frac{\phi i}{2}} \quad \text{and} \quad w_2 = -\sqrt{r}\, e^{\frac{\phi i}{2}},$$

and these two functions together just exhaust the values of the multiple-valued function $\sqrt{z}$. Let us, therefore, consider two planes instead of one, each severed along the cut in question and lying one above the other like the leaves of a book, and assign the values w_1 to the points of the one plane, w_2 to those of the other. We observe, furthermore, that the values of w_1 along the upper side of the cut in its leaf and those of w_2 along the lower side of the cut in the second leaf agree with each other. Let these two edges be united, so that z, moving continuously in the surface thus formed, will pass from leaf I to leaf II without interruption when it crosses the positive axis of reals from the upper side. Similarly the values of w_1 along the lower edge of the cut in leaf I and those of w_2 along the upper edge of the cut in leaf II correspond. Hence we shall unite these two edges. The final result is a closed surface of two sheets in which the function $\sqrt{z}$ is single-valued. The sheets cut through each other along a line; but the point z in crossing this line is not at liberty to pass into either sheet. z has not come to a fork in the road, but to a switch which has already been set, and its further course is definitely determined.

The point $z = 0$ is called a *branch-point*, the cut a *junction-line*.

More generally, let

$$G(w, z) = A_0(z)w^m + A_1(z)w^{m-1} + \ldots + A_m(z) = 0$$

be an algebraic equation. Then to each value

of z correspond in general m distinct values $w_1, \ldots, w_m$. Mark the points $a_1, \ldots, a_K$ (finite in number) for which this is not the case. Draw a curve C, not cutting itself, through these points and continue C from the last point to $z = \infty$. Then spread out m leaves over the z-plane and cut each leaf along C. The m values $w_1, \ldots, w_m$ of the function can now be assigned to the points of these leaves so as to form m single-valued functions analytic throughout these regions. Finally, corresponding edges of the leaves are to be connected along each of the segments into which C is divided by the points $a_1, \ldots, a_K, \infty$. The result is a closed surface on which w is a single-valued function of z. If $G(w, z)$ is irreducible, the surface will consist of a single piece, and conversely. A branch-point in which μ leaves are connected in cycle is said to be of *order* $\mu - 1$.

The surfaces here described are due to Riemann (Göttingen, thesis for the doctorate, 1851) and are known as *Riemann's Surfaces*. Corresponding to any given analytic function there can always be constructed a Riemann's surface on which the function becomes single-valued. In all ordinary cases the leaves are joined together in cycle in branch-points, and they always pass over into each other along junction lines, never merely at isolated points. See Analysis Situs.

13. Analytic Continuation.—If a function $f(z)$ be single-valued and analytic in a region S, it may happen that the function can be

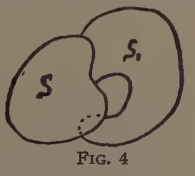

Fig. 4

defined in an adjacent region S_1 in such a way that the extended function is analytic throughout the enlarged region (S, S_1). In this case $f(z)$ is said to be *continued analytically* beyond the region S into the region S_1. If S_1 overlaps S, it will in general be necessary to introduce a Riemann's surface for the extended function.

Consider, for example, a function given by the power series (4). Let $z_0 \neq 0$ be an interior point of the circle of convergence K. Develop the function by Taylor's Theorem about the point z_0. The new power series, which proceeds according to powers of $z - z_0$, will surely converge within a circle tangent internally to K, and it may converge throughout a larger circle K_1. In the latter case analytic continuation is possible, the region S_1 corresponding to the part of K_1 exterior to K.

We are now in a position to complete the definition, according to Weierstrass, of an analytic function. Let $f(z)$ be analytic in a given region S. Continue $f(z)$, if possible, analytically beyond S. Repeat this step so long as it is possible to do so. The most extended function that can thus be generated out of the given function is known as the *monogenic analytic function* $f(z)$. It is uniquely determined by the values of $f(z)$ in S. Weierstrass employed the method of overlapping circles and power series for obtaining the successive analytic continuations. The function is completely defined as soon as any one of these power series, called *elements*, is known.

The rational functions and the elementary functions e^z, $\log z$, etc., are examples of monogenic analytic functions. By an *algebraic function* is meant any monogenic analytic function which satisfies an algebraic equation, $G(w, z) = 0$, where G denotes a polynomial. Every irreducible algebraic equation in w and z defines such a function.

Two analytic functions which agree in value with each other along an arc of a curve, however short, lying wholly within their domain of definition, are identical throughout their whole extent.

It may happen that the singular points of an analytic function are not isolated, but exist in every internal of a curve (for example an arc of the whole circumference of a circle, the latter being the case with the function defined by the series

$$\sum_{n=1}^{\infty} z^{n!}$$

throughout the interior of the unit circle $|z| < 1$), so that the function is analytic up to the curve, but cannot be extended beyond it. Such a curve is called a *natural boundary*. A region of the plane into which a given function cannot be continued analytically is called a *lacunary* space.

14. Reflection in Analytic Curves.—A curve which can be represented by the equations

$$x = f(t), \quad y = \phi(t), \quad a \leq t \leq b,$$

where f and ϕ are both developable by Taylor's Theorem about every point t_0 of the above interval and where, furthermore, $f'(t)$ and $\phi'(t)$ never vanish simultaneously in the interval, is called an *analytic curve*.

Let S be a region bounded in part or wholly by an analytic curve Γ having no multiple point. If

$$u + vi = f(z)$$

is analytic in S and takes on real boundary values along Γ, then $f(z)$ can always be continued analytically across Γ. In particular, let Γ be an arc of a circle. Then the analytic continuation is effected by inverting S in this circle and assigning to $f(z)$ in the transformed points values conjugate to those in the original points. The method is fundamental in the study of minimum surfaces, and of the elliptic modular and the automorphic functions.

15. Dirichlet's Principle.—In order to show that a simply connected region S can be mapped in a one-to-one manner and conformally on a circle (§ 4), it is necessary to establish the existence of a function u which (a) is single-valued and continuous in S, (b) satisfies Laplace's Equation (§ 6) throughout the interior of S, and (c) takes on preassigned values along the boundary of S. In similar cases in mathematical physics Gauss, Thomson and Dirichlet had attempted to give a proof of the existence of such a function by making connections with a skilfully constructed corresponding problem of the Calculus of Variations. Riemann adopted this method in order to obtain his existence proofs, both for the present problem and for the case of algebraic functions corresponding to a preassigned Riemann's surface. The problem of the Calculus of Variations which matches the present problem is as

follows: To find a function u which is continuous in S, together with its first derivatives, takes on the prescribed boundary values, and makes the integral

$$\int_S \int \left[\left(\frac{\partial u}{\partial x}\right)^2 + \left(\frac{\partial u}{\partial y}\right)^2 \right] dS$$

a minimum. If such a function exists and if, furthermore, it has continuous second derivatives, then it will satisfy Laplace's Equation within S and thus yield the desired solution. It was assumed by the mathematicians named above that the problem of the Calculus of Variations necessarily has a solution. This method of proof is known as *Dirichlet's Principle*. Weierstrass pointed out the insufficiency of the reasoning involved in the assumption to which we have just called attention. Other methods of proof were then devised by Schwarz and Neumann. Recently Hilbert has, with considerable labor, partially filled the gap in the original method.

16. Weierstrass's and Mittag-Leffler's Theorems.—It is always possible to form a polynomial which has n roots situated arbitrarily in the complex plane. The question presents itself as to whether this theorem can be extended to transcendental integral functions. This question Weierstrass answered in 1876 as follows: Let $a_0, a_1, \ldots$ be any set of points in the complex plane such that $\lim a_n = \infty$ when $n = \infty$. Then there exists an integral transcendental function $G(z)$ which has in each of the points a_n a zero of arbitrarily preassigned order, and does not vanish for any other value of z. The most general such function is given by the formula

$$G(z) = e^{\Gamma(z)} \mathfrak{G}(z),$$

where $\mathfrak{G}$ denotes a particular function of the class in question and Γ is a rational or transcendental integral function. This theorem has formed the point of departure for many recent researches, chiefly of French mathematicians.

Mittag-Leffler's Theorem: Let $a_0, a_1, \ldots$ be any set of points in the complex plane such that $\lim a_n = \infty$ when $n = \infty$. In each of these points let an arbitrary polynomial in $1/(z - a_n)$:

$$f_n(z) = \frac{A_1^{(n)}}{z - a_n} + \frac{A_2^{(n)}}{(z-a_n)^2} + \ldots + \frac{A_\kappa^{(n)}}{(z-a_n)^\kappa},$$

be chosen. Then there exists a single-valued function $F(z)$ analytic throughout the whole plane except at the points a_n and behaving in each of these points like $f_n(z)$; i.e., the difference

$$F(z) - f_n(z)$$

has no singularity in the point a_n. The most general such function is given by the formula

$$F(z) = \mathfrak{F}(z) + G(z),$$

where $\mathfrak{F}$ denotes a particular function of the class in question and G is an integral function, rational or transcendental.

17. Elliptic and Abelian Integrals.—The motion of a simple pendulum and the length of the arc of an ellipse lead respectively to the elliptic integrals

$$\int_0^x \frac{dx}{y}, \quad \int_0^x \frac{y\,dx}{1-x^2},$$

where $y^2 = (1 - x^2)(1 - k^2x^2)$, $0 < k < 1$.

If we set the first of these integrals equal to w and let x take on complex values z, then the inverse function z defined by

$$w = \int_0^z \frac{dz}{\sqrt{(1-z^2)\,(1-k^2z^2)}},$$

turns out to be a single-valued function of its argument w having two linearly independent periods (§ 18) and being analytic throughout the whole w-plane except for poles.

A generalization which now presents itself is the following: The integrand in each of the foregoing cases is a rational function of x and y, and these variables are connected by an algebraic equation. Consider, therefore, generally an algebraic equation

$$G(w, z) = 0,$$

where G denotes an irreducible polynomial in w and z, and construct the Riemann's surface corresponding to it. Let $R(w, z)$ be any rational function of w and z. Then, setting w equal to the algebraic function of z defined by the foregoing equation, we have in $R(w, z)$ a function which is singled-valued and in general continuous on the above surface. If now we extend the definite integral

$$\int_{(w_0, z_0)}^{(w, z)} R(w, z)\,dz$$

along an arbitrary path on the surface, we have before us an *Abelian Integral*. It is obvious that the logarithm and the inverse trigonometric functions, e.g.,

$$\sin^{-1} z = \int_0^z \frac{dz}{w}, \quad z^2 + w^2 = 1,$$

are special cases of Abelian integrals. When the equation $G = 0$ is of the form $w^2 = f(z)$, where $f(z)$ denotes a polynomial in z of degree > 4 having all distinct linear factors (or can be thrown into this form by means of birational transformations), the integral is called a *hyperelliptic integral*.

The only Abelian integrals whose inverse function is single-valued are those which lead to the exponential (including trigonometric) and the elliptic functions. The *Abelian Functions* are single-valued periodic functions, not of a single argument, but of p independent variables, where p denotes what is known as the deficiency of the corresponding Riemann's surface $G(w, z) = 0$. They have $2p$ periods. These functions arise as the inverse functions $z_\kappa(w_1, \ldots w_p)$, $(\kappa = 1, \ldots, p)$ of a system of p equations:

$$w_\lambda = \int_{a_1}^{z_1} \phi_\kappa dz_1 + \ldots + \int_{a_p}^{z_p} \phi_\kappa dz_p,$$

where the integrals $\int \phi_\kappa dz$ are p linearly independent Abelian integrals on the Riemann's surface for $G(w, z) = 0$.

18. Automorphic Functions.—A function $f(z)$ is said to admit a linear transformation into itself if

$$f\left(\frac{\alpha z + \beta}{\gamma z + \delta}\right) = f(z),$$

where $\alpha, \ldots \delta$ are constants and $\alpha\delta - \beta\gamma \neq 0$. A familiar class of such functions are the

periodic functions. Here the transformation reduces to a translation:

$$f(z+\omega)=f(z).$$

The most general single-valued periodic functions of a single variable z, which are in general analytic, are the *simply* and *doubly periodic functions*, i.e., those functions whose periods can all be expressed as integral multiples $n\omega$ of a single primitive period ω, or else in the form $n\omega+n'\omega'$, where ω and ω' form a primitive pair of periods. In the latter case ω/ω' cannot be a real quantity.

If the coefficients are integers and $\alpha\delta-\beta\gamma=\pm 1$, we have the *elliptic modular functions.* More generally the coefficients may have non-integral values, being restricted only in such a way that the transformations form a «discrete group.» These most general functions, including the special cases above mentioned, are known as the *automorphic functions.*

19. Definite Integrals.—The Γ-function may be defined by the definite integral

$$\Gamma(z)=\int_0^\infty t^{z-1}e^{-t}dt,$$

the variable of integration t being real and positive. This integral converges only for values of z which lie to the right of the axis of pure imaginaries: $z=x+yi$, $x>0$. A new definite integral can be formed as follows which converges for all values of $z\neq -n$, where n denotes a positive integer, namely,

$$\int_C t^{z-1}e^{-t}dt,$$

extended over the loop indicated in the figure.

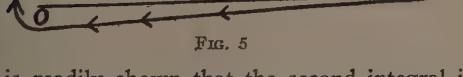

FIG. 5

It is readily shown that the second integral is equal to the first multiplied by $1-e^{2\pi iz}$ for all values of z for which the first integral converges. Hence we have generally

$$\Gamma(z)=\frac{1}{1-e^{2\pi iz}}\int_C t^{z-1}e^{-t}dt.$$

By means of this integral the Γ-function has been systematically treated.

The above is an example of a *loop integral,* i.e., a definite integral extended over a certain *loop-circuit.* Such integrals have been generalized, being extended over *double circuits,* and these latter integrals are an aid in the study of the solutions of certain linear differential equations.

20. Functions of Several Variables.—In each of n complex planes let a region $S_1,\ldots,S_n$ be given, and let z_κ be an arbitrary point of S_κ. Then the set of values $(z_1,\ldots,z_n)$ is called from analogy with the case $n=1$ a *point.* The totality of these points constitutes the *region* (S). In every point of S let a function $f(z_1,\ldots,z_n)$ be uniquely defined. The idea of the limit and of continuity can be extended at once to such a function. $f(z_1,\ldots,z_n)$ is said to be *analytic in* (S) if it is continuous in (S) and if, furthermore, when all the z_κ but one,—z_m, let us say,—are held fast, f is then analytic in S_m; this condition to be satisfied for $m=1,\ldots,n$. For brevity let $n=2$. Cauchy's Integral Formula becomes

$$f(z_1,z_2)=\frac{1}{(2\pi i)^2}\int_{C_1}\frac{dt_1}{t_1-z_1}\int_{C_2}\frac{f(t_1,t_2)dt_2}{t_2-z_2}$$

The function can furthermore be developed by Taylor's Theorem as follows: Let (a_1,a_2) be an interior point of (S), and let K_κ be the largest circle that can be drawn in S_κ about a_κ as centre, containing in its interior no boundary point of S_κ. Then

$$f(z_1,z_2)=\sum_{l=0,\,m=0}^{\infty}c_{lm}(z_1-a_1)^l(z_2-a_2)^m,$$

where

$$c_{lm}=\frac{1}{l!m!}\left.\frac{\partial^{e+m}f(z_1,z_2)}{\partial z_1^{\,l}\,\partial z_2^{\,m}}\right|_{(a_1,a_2)}$$
$$=\frac{1}{(2\pi i)^2}\int_{C_1}\frac{dt_1}{(t_1-a_1)^{l+1}}\int_{C_2}\frac{f(t_1,t_2)dt_2}{(t_2-a_2)^{m+1}},$$

and z_κ is an arbitrary interior point of the circle K_κ. We have, as in the case $n=1$,

$$|c_{lm}|\leq Mr_1^{-l}r_2^{-m},$$

where $|z_1-a_1|=r_1$, $|z_2-a_2|=r_2$.

The idea and the method of analytic continuation can be extended without difficulty to functions of several variables, and thus the *monogenic analytic function* is completely defined. For implicit functions and analytic configurations lying in hyperspace the reader is referred to the author's report in the *Encyklopädie,* §§ 44 and 47 (see below).

The following theorem is due to Weierstrass: Let $(b, a_1,\ldots, a_n)$ be an interior point of a region (S) in which $f(w, z_1,\ldots, z_n)$ is analytic. Let f vanish at this point; but $f(w, a_1,\ldots, a_n)$ shall not vanish identically. Then

$$f(w,z_1,\ldots,z_n)=\{w^m+A_1w^{m-1}+\ldots+A_m\}\phi,$$

where $\phi(w, z_1,\ldots, z_n)$ is analytic throughout a certain neighborhood of the point $(b, a_1,\ldots, a_n)$ and does not vanish there, while each of the coefficients $A_1(z_1,\ldots, z_n)$, $\ldots$, $A_m(z_1,\ldots, z_n)$ is single-valued and analytic throughout a region including the point $(a_1,\ldots, a_n)$ in its interior. The excluded case $f(w, a_1,\ldots, a_n)\equiv 0$ is also treated by Weierstrass.

WILLIAM F. OSGOOD,
Professor Emeritus of Mathematics, Harvard University.

COMPLEXION, the term generally used to signify the special color or hue of a person's skin. The human skin, till the time of Malpighi, was supposed to consist only of two parts—the epidermis or outer skin, and the cutis or

true skin; but that anatomist, about the middle of the 17th century, discovered between these a cellular texture, soft and gelatinous, to which the names of rete mucosum, rete Malpighi, or Malpighian tissue, have been given. He demonstrated the existence of this membrane at first in the tongue and in the inner parts of the hands and feet; but by his subsequent labors, and also by those of Ruysch and other anatomists, it was proved to exist, between the epidermis and cutis, in all parts of the human body. Malpighi, on the discovery of this membrane, offered a conjecture respecting the cause of the color of negroes. He supposed that this membrane contained a juice or fluid of a black color, from which their blackness arose. The actual existence of a black pigment has been since ascertained. The rete mucosum is of very different colors in different nations; and the difference of its color so completely agrees with the difference of their complexions, that there can be no doubt that it is the sole, or, at least, the principal seat of the color of the human complexion. Its thickness varies in different parts of the body; and the depth of its color, for the most part, is in proportion to its thickness. It is now, however, not regarded as altogether a distinct tissue, being considered rather as the innermost and newest layer of the epidermis or cuticle. The black color of the negroes is destroyed by whatever destroys the rete mucosum, as wounds, burns, etc.; the scar remaining white ever afterward. The greatest contrast in complexion is between the fair white peoples of northern Europe and the ebony-colored negro of Africa.

The nature and color of the hair seem closely connected with the complexion. In proportion to the thinness of the skin and the fairness of the complexion the hair is soft, fine and of a white color; this observation holds good not only in the great varieties of the human race, but also in albinos. Next to them in fairness of complexion is the Teutonic race, the *rutilæ comæ* (fair locks) of whom were a distinguishing characteristic even in the time of the Romans. The Celtic people are not so fair as the Teutonic, and their hair is darker and less inclined to curl; but it is perhaps more difficult than in the case of the Teutons to be sure of unmixed blood. But though the color of the hair is evidently connected with the complexion, yet its tendency to curl does not appear to be so. Many brown-complexion Celts have curled hair; the Mongolian and American races, of a much darker complexion, have hair of a darker color, but long and straight. Among that portion of the Malay race which inhabits some of the South Sea Islands, soft and curled hair is said to be met with. The color of the eye is also connected with the complexion. In the African, Professor Sommering remarks that the white of the eye is not so resplendently white as in Europeans, but rather of a yellowish brown, something similar to what occurs in the jaundice. The iris in the negroes, in general, is of a very dark color; but the iris in the Kongo negro is said to be frequently of a bluish tinge. The Teutonic tribes are not more distinguished by their fair complexion than by their blue eyes, —*cærulei oculi*, while the iris of the darker-colored Finn is brown, and that of the still darker Laplander black. The color of the eyes also follows, in a great degree, in its changes, the variations produced by age in the complexion. The most singular class of people in point of complexion are the albinos, but albinoism is not confined to the human race. An intermediate complexion is produced where children are born from parents of different races. If the offspring of the darkest African and the fairest European intermarry successively with Europeans, in the fourth generation they become white; when the circumstances are reversed, the result is reversed also. Along with the successive changes of complexion is also produced a change in the nature and color of the hair; though, in some instances, the woolly hair remains when the complexion has become nearly as fair as that of brown people in Europe. It does not, however, always happen that the offspring is of the intermediate color between that of the respective races to which the father and mother belong; it sometimes resembles one parent only, while perhaps, in the second or third generation, the color of the other parent makes its appearance. An instance has been given of a negress who had twins by an Englishman: one was perfectly black; its hair was short, woolly and curled; the other was white, with hair resembling that of a European. In another case the child of a black man and an English woman was quite black; and still more remarkable: a black married a white woman, who bore him a daughter, resembling the mother in features, and as fair in all respects, except that the right buttock and thigh were as black as the father's.

The generally received opinion concerning the varieties of complexion which are found in the different races of man throughout the globe is, that they are caused entirely by the influence of climate. Respecting the primary color of man the supporters of this opinion are not agreed. The opinion that climate alone will account for the various complexions of mankind is very plausible, and supported by the well-known facts that in Europe the complexion grows darker as the climate becomes warmer; that the complexion of the French is darker than that of the Germans, while the natives of the south of France and Germany are darker than those of the north; that the Italians and Spaniards are darker than the French, and the natives of the south of Italy and Spain darker than those in the north. The complexion also of the people of Africa and the East Indies is brought forward in support of this opinion; and from these and similar facts the broad and general conclusion is drawn, that the complexion varies in darkness as the heat of the climate increases; and that, therefore, climate alone has produced this variety. But it can be shown that the exceptions to this general rule are very numerous; that people of dark complexions are found in the coldest climates, people of fair complexions in warm climates, people of the same complexion throughout a great diversity of climate, and races differing materially in complexion dwelling near together.

1. In the coldest climates of Europe, Asia and America we find races of a very dark complexion. The Laplanders have short, black, coarse hair; their skins are swarthy, and the irides of their eyes are black. According to Crantz the Greenlanders have small, black eyes; their body is dark gray all over; their face brown or olive; and their hair coal-black.

The complexion of the Samoiedes and other tribes who inhabit the north of Asia is very similar to that of the Laplanders and Greenlanders, who are Eskimos by race. Humboldt's observations on the South American Indians illustrate and confirm the same fact. If climate rendered the complexion of such of these Indians as live under the torrid zone, in the warm and sheltered valleys, of a dark hue, it ought also to render or preserve fair the complexion of such as inhabit the mountainous part of that country; for certainly, in point of climate, there must be as much difference between the heat of the valleys and of the mountains in South America as there is between the temperature of southern and northern Europe; and yet this authority expressly assures us that "the Indians of the torrid zone, who inhabit the most elevated plains of the Cordillera of the Andes, and those who, under the 45th degree of south latitude, live by fishing among the islands of the archipelago of Chonos, have as coppery a complexion as those who, under a burning climate, cultivate bananas in the narrowest and deepest valleys of the equinoctial region." He adds, indeed, that the Indians of the mountains are clothed, but he never could observe that those parts which were covered were less dark than those which were exposed to the air. The inhabitants also of Tierra del Fuego, one of the coldest climates in the world, have dark complexions and hair.

2. Fair-complexioned races are found in hot climates. Ulloa informs us that the heat of Guayaquil is greater than at Carthagena; and by experiment he ascertained the heat of the latter place to be greater than the heat of the hottest day at Paris; and yet in Guayaquil, "notwithstanding the heat of the climate, its natives are not tawny"; indeed they are "so fresh-colored, and so finely featured, as justly to be styled the handsomest, both in the province of Quito and even in all Peru." According to a statement of Humboldt, in the forests of Guiana, especially near the sources of the Orinoco, "are several tribes of a whitish complexion of whom several robust individuals, exhibiting no symptom of the asthenical malady which characterizes albinos, have the appearance of true Mestizos. Yet these tribes have never mingled with Europeans, and are surrounded with other tribes of a dark brown hue." The inhabitants of Boroa, a tribe in the heart of Araucania, are white, and in their features and complexion very like Europeans. Even in Africa darkness of complexion does not increase with the heat of the climate in all instances; the existence of comparatively fair races in this quarter of the globe is noticed by Ebn Haukal, an Arabian traveler of the 10th century, and has been confirmed by subsequent travelers.

3. The same complexion is found over immense tracts of country, comprehending all possible varieties of climate. The most striking and decisive instance of this is on the continent of America, all the inhabitants of which, with the exception of the Eskimo, exhibit the copper-colored skin and the long and straight black hair. Australia is an instance of a similar nature, though on a less extensive scale: over the whole of the island, even in the comparatively cool climate of the southern parts, the complexion of its inhabitants is of a deep black, and their hair is curled like that of negroes.

4. Different complexions are found under the same physical latitude, and among the same people. Illustrations and proofs of this have already been given. The physical latitude in which the Norwegians, the Icelanders, the Finns and the Laplanders live scarcely differs; and yet their complexion, and the color of their eyes and hair, are widely different. There is a great diversity of color and features among the Morlachs, who inhabit Dalmatia. The inhabitants of Kotar, and of the plains of Seigu and Knin, have fair blue eyes, broad face and flat nose. Those of Duare and Vergoraz, on the contrary, have dark-colored hair; their face is long, their complexion tawny and their stature tall. M. Sauchez, who traveled among the Tartars in the southern provinces of Russia, describes a race or tribe as having countenances as white and fresh as any in Europe, with large black eyes. In the south of Africa we find the Kafirs, who are of a brown or iron-gray color, and the Hottentots of a yellow color. In the island of Madagascar, according to Mr. Sibree, the observer "finds almost every shade of color from a very light olive, not darker than is seen in the peoples of southern Europe, down through all gradations of brown to a tint which although not black is certainly very dark. In the quality of the hair, too, there is a good deal of difference; the lighter-colored people having usually long, black and straight hair, while the darker tribes have, as a rule, shorter and more frizzly hair."

Besides a Malayan olive-colored race, people with the negro complexion and features are found in the Philippine Islands; and in Java, the Hindu and Malay character may be clearly traced in the complexion and features of the two classes of inhabitants which are found in that island. In several of the Moluccas is a race of men who are blacker than the rest, with woolly hair, inhabiting the interior, hilly parts of the country. The shores of these islands are peopled by another nation, whose inhabitants are swarthy, with curled, long hair. In the interior hilly parts of Formosa the inhabitants are brown, frizzle-haired and broad-faced; while the Chinese occupy the shores.

It is observed that there are two great varieties of people in the Pacific islands; the one more fair, the other blacker, with their hair just beginning to be woolly and crisp. The first race inhabits Tahiti and other of the Society Islands, the Marquesas, the Friendly Isles, Easter Island and New Zealand; the second race peoples New Caledonia, Tanna and the New Hebrides, especially Mallicolo. If we examine the relative situation and latitudes of these islands on a map, we shall be convinced not only that darker complexioned people are found where the climate is comparatively colder, but that the same complexion is found under very different latitudes. It is not meant to be denied that a burning climate will render the complexion very dark, and that a climate of less extreme heat will bronze the complexion of the fairest European; but there are some material points in which the dark complexion of the Caucasian, or naturally fair-skinned variety of mankind, caused by climate, differs from the dark complexion of all the other varieties of the human race.

1. The offspring of the Caucasian variety is born fair; the offspring of the other varieties is

born of the respective complexion of their parents. Ulloa informs us that the children born in Guayaquil of Spanish parents are very fair. The same is the case in the West Indies. Long, in his history of Jamaica, expressly affirms "that the children born in England have not, in general, lovelier or more transparent skins than the offspring of white parents in Jamaica." But it may be urged that this is not the case with respect to the other nations of the Caucasian variety, who have been settled in warm climates from time immemorial, and that the question ought to be decided by the Moors, Arabians, etc. Their children, however, are also born fair complexioned, as fair as the children of Europeans who live under a cold climate. Russell informs us that the inhabitants of the country round Aleppo are naturally a fair complexion, and that women of condition, with proper care, preserve their fair complexion to the last. The children of the Moors, according to Shaw, have the finest complexions of any nation whatsoever; and the testimony of Poiret is directly to the same effect. "The Moors are not naturally black, but are born fair, and when not exposed to the heat of the sun remain fair during their lives."

2. Individuals belonging to the Caucasian variety, that inhabit warm countries, preserve their native fairness of complexion if they are not exposed to the influence of the climate; while there is a uniform black color over all the parts of a negro's body. The hue which Europeans assume is the same, though the tinge may be lighter or darker, whether they settle in Africa, the East Indies or South America. They do not become, like the natives of those countries, black, olive-colored or copper-colored; their complexion merely resembles that of a tanned person in this country, only of a darker tinge. The negroes that are settled in the West Indies or America do not assume the copper color of the Indians, even though a milder climate may have some effect on the darkness of their complexions. The children of Europeans, of negroes and of Indians are all born, in America, of the same reddish hue; but in a few days those of the negro begin to assume the black complexion of their parents, those of the Indian the copper complexion, while those of the European either continue fair, if kept from the influence of the sun, or become tanned; not black like the negro, or copper-colored like the Indian, if exposed to its influence. Europeans who settle in Canada, or in the northern parts of America, where the climate resembles that of their native country, do not assume the complexion of the Indians, but continue fair like their ancestors. The same observation may be made respecting the Russians who are settled among the Mongolian variety, in those parts of the Soviet Union in Asia, the climate of which resembles the middle or northern parts of European Russia. Indeed the wide extent of country over which the Mongolian variety is spread, including the extreme cold of Lapland and the north of Asia, the mild temperature of the middle parts of that continent, and the warmth of the southern parts of China, is in itself a proof that dark complexion does not arise either from the influence of heat or cold.

Lastly, radical varieties of complexion are always accompanied with radical varieties of features. We do not find the olive color of the Mongolian variety with the features of the Malay; nor the brown color of the Malay with the features of the Mongolian; nor the black skin of the Ethiopian variety, or the red color of the American, united with any set of features but those which characterize their respective varieties. It, however, by no means follows that the hypotheses of different races having been originally formed must be adopted, because climate is not adequate to the production of the radical varieties of complexion which are found among mankind. Man, as well as animals, has a propensity to form natural varieties; and the variations may in process of time involve all the tissues so as to yield permanent differences in color and quality of hair, color of skin, size and form of bones, especially those of the skull and limbs. See EPIDERMIS; HISTOLOGY; MALPIGHI; RACES, ORIGINS OF.

COMPLINE, the last or seventh of the daily canonical hours in the Roman Catholic breviary; the complement of the Vespers or evening office. Saint Benedict, in the 6th century, added Compline to the hours, thus making the number seven, answering to the praises of which the psalmist speaks of "seven times a day." Matins and lauds were classed as one hour.

COMPLUTENSIAN POLYGLOT, the earliest complete polyglot edition of the Bible compiled and printed in Alcolá. It was made by seven scholars under the auspices and at the expense of Cardinal Ximenes. It was begun in 1502, and finished in 1517, but was not actually published till 1522. It consists of six folio volumes. In the Old Testament, on the left hand page, are the Hebrew original, the Latin Vulgate and the Greek Septuagint; and on the right hand page, the Vulgate, the Septuagint, with Latin translation above, and the Hebrew, with primitives belonging to that language on the outer margin. At the lower part of the page are two columns used for a Chaldee paraphrase and a Latin translation. The Greek Testament, constituting part of the Complutensian Polyglot, was the first complete edition of that part of Scripture printed.

COMPOSING-MACHINES, a general title for all classes of machines that compose or set either type or matrices, arranging them in lines and columns for printing. There are four prominent types of these: (1) Those that set matrices in line and cast therefrom a solid line or slug, as the Linotype, Intertype, Linograph and Monoline; (2) those that cast and set type, as the Monotype and Graphotype; (3) those that set and distribute ordinary founders' type, these being the only ones properly styled type-setting machines, as the Thorne (or Unitype), McMillan, Empire, Dow, Fraser, Kastenbein, etc.; and (4) those that impress male dies into soft material and cast lines from these impressions.

Historically, the type-setting machine comes first, William Church of Connecticut devising a machine, which was patented in England in 1822, that was the first practical effort in this direction. He employed a keyboard, and stored the type in channels. From 1842 to 1872 there were 57 United States patents granted on composing machines, and from 1822 to 1872 a like number were patented in Great Britain. The

The linotype.

most noteworthy of these were the Mitchell and the Alden machines in the United States, and the Kastenbein, Hattersley and Fraser machines in England. These machines all came into use during the period between 1853 and 1872, and a few may still be found in operation in England. The difficulty with all of them seems to have been that they required several persons to operate each machine, and that the consequent cost was very nearly the same as for composition by hand. From 1872 up to 1880 there were invented or constructed over 50 different machines designed to supersede the compositor, practically all of which failed of commercial success. During the period between 1880 and 1890 the Thorne type-setting machine, originating in Connecticut, came into considerable use, being employed by many newspapers throughout the United States, and beginning to find a market abroad. During this period the Burr and McMillan machines also found some sale in the United States, and the Fraser, Hattersley and Kastenbein in England and Germany. In 1898 the Thorne was remodeled and renamed the Simplex, and later the Unitype.

Of all the machines devised for setting founders' type, the Unitype was most successful, but its manufacture was practically discontinued about 1914. The types are contained in 90 channels, set radially in the periphery of an upright cylinder. As the operator fingers the keys, the types called for are pushed out of the lower ends of the channels and carried around on a circular raceway to the point where they are brought into line. A second operator draws to him from the composed type thus emerging enough to form a line of the desired length. This he puts in the galley and justifies, or spaces out to length, by hand. The leads, or spaces between lines, are also inserted by this operator. The type is distributed by an upper grooved cylinder, this being performed automatically in the later machines. In the last models of this machine one operator did (or could do) all the work.

The Empire machine, first known as the Burr, was a modification of the Kastenbein. It was produced in New York, and required three operators. It therefore fell into disuse as the one-man machines became common. Nickel type was employed, and a machine would handle only one body size of type.

The McMillan machine, developed in Ilion, N. Y., was provided with automatic justification, thus dispensing with the labor of one operator. The distributor was a separate machine, operating quite simply at a speed of about 10,000 ems an hour. These machines were used for some years by the New York *Sun* and the DeVinne Press.

The Cox type-setting machine attracted considerable notice in the printing trade in Chicago and New York in 1898. The most unique feature of Cox's machine was the employment of crimped or corrugated spaces made of lead. The line was overset in length, and then squeezed down to measure by compressing the corrugations. This justification was satisfactory in some respects, but the crimped spaces created difficulty in many others, and its use was abandoned.

The Calendoli type-setting machine, developed in France by a priest of that name, attracted much attention because of the wonderful claims made for its speed. Though exploited for several years, it was never perfected for the market. It employed short types grooved so as to slide on rails, and the keyboard had numerous combinations to enable the operator to strike whole words or syllables at a single motion of the hand.

There was exhibited at the Pan-American Exposition in Buffalo, in 1901, a one-man type-setting machine that appeared to work successfully. It was the invention of Alexander Dow, and handled founders' type, being adapted to use the several sizes in one machine. The justification or spacing out of the lines was entirely automatic, requiring no thought by the operator. Had this machine been brought out at an earlier date, doubtless it would have secured a large sale.

Among other composing-machines that have been built in the United States, and attracted the attention of the printing trade at one time or another, are the Converse, projected about 1894, which did good work, but was obstructed by previous patents; the Paige, on whose development nearly $2,000,000 was spent, and which proved too costly to construct for the general market, the two machines built being now stored with Cornell and Columbia universities as mechanical curiosities; the St. John Typobar, consisting of cold-pressed metal clamped on a steel base, to form a line; the Lagerman Typotheter or Chadwick, a little machine for enabling a compositor to set type with both hands; the Johnson, which justified the lines by sawing a space of the required width; the composite type-bar machine, in which short, notched type were transformed into a line or type-bar by casting metal around their bases and between them; the Sears, in which dies were impressed in a block of wood, and a slug cast from the matrix thus formed; the Risley and Lake, in which the type were impressed in a soft sheet like blotting paper, and a stereotype taken after a quantity had been thus impressed, and the Heath Matrix Typograph, of the same class; and the Goodson Graphotype, which resembled the Monotype, but was much smaller, employing only 100 characters. The Graphotype was later rebuilt, but failed to find commercial sale.

The Scudder Monoline machine produces a slug like that of the Linotype, and was barred out of the United States as an infringing machine. It was much smaller than the Linotype and did a more restricted class of work. Early in the present century it passed into the hands of the Mergenthaler Linotype Company, and was never placed on the American market.

The Linotype is a machine designed to do the work of both type setting and type casting, by substituting for lines of individual type metal bars or slugs with raised letters on one edge. These bars, when arranged in page form, have the same appearance as pages of separate type and may be used either to print from direct or to produce stereotype or electrotype plates in the usual manner. The machine will produce type faces of any kind desired, from 5 to 36 point, some up to 60 point; requires but one operator, and gives a product equal to five or six hand compositors, furnished with ordinary type.

The Linotype was invented in 1885 by Ottmar Mergenthaler, a German by birth, then liv-

ing in Baltimore, and first put into practical use by the New York *Tribune* in 1886. Since then it has come into general use by newspapers and printing offices throughout the world.

The machine contains as fundamental elements several hundred brass matrices. Each matrix consists of a flat plate having in one edge a female character or matrix proper, and in the upper end a series of teeth which are used for distributing the matrices to their proper places in the magazine of the machine. Matrices are also made having two characters, Fig. 1, as for instance, a Roman and Italic letter, either of which may be used at will. There are in the machine a number of matrices for each letter, and also matrices representing special characters and spaces.

The general organization of the machine is shown in outline in Fig. 2. A represents an inclined fixed magazine, containing channels in which the assorted matrices are stored and through which they slide, entering at the upper and escaping at the lower end, one at a time. Each channel in the magazine has at the lower end an escapement B, connected by a rod C with a finger key D, representing the letter or character of the matrices in the corresponding channel. There is a key for each character, and also keys for quads and for the wedge spacers.

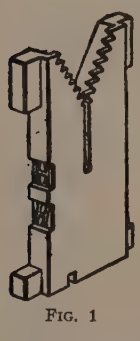

FIG. 1

The operation of the various keys results in the selection of the matrices and spacers and their collection in assembler G, until it contains all the characters to be represented in one line of print. After the line is thus composed, it is transferred mechanically, through the path indicated by dotted lines in Fig. 2, to a position in

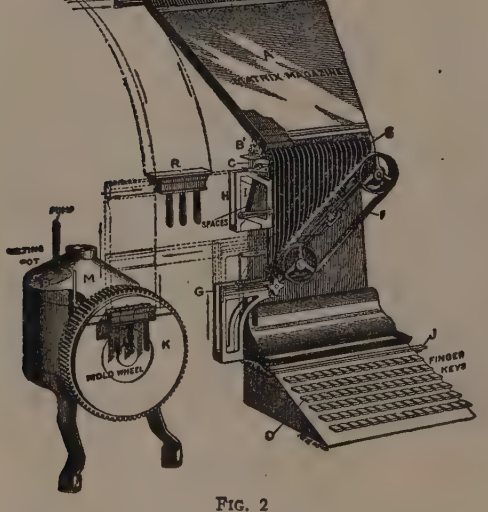

FIG. 2

front of a mold or slot extending through the wheel K, from its front to its rear face. This mold is of the size and shape of the slug or line of type required, and it determines both the measure and the body of the line. While the line is in place in front of the mold, the wedge spacers are pushed up through the line, which is instantly and exactly justified thereby.

Behind the mold, there is a melting pot M, heated by flame from a gas, gasoline or electric heater. After the matrix line is in place against the front of the mold, as shown in Fig. 2, a pump forces the molten metal through the pot mouth into the mold, against and into the characters in the matrix line. The metal instantly solidifies, forming a slug having on its edge raised characters formed by the matrices. The slug is then automatically removed from the mold, being trimmed to the proper length and thickness by knives. The line is then lifted from the mold and shifted laterally, until the teeth in the upper end of the matrices engage the horizontal ribs on a bar which rises, as shown by dotted line at R, lifting the matrices to the distributor at the top of the machine. The matrices pursue a circulatory course through the machine, starting singly from the bottom of the magazine, passing thence to the line being composed, thence to the mold, and finally back to the top of the magazine. This circulation permits the operations of composing one line, casting from a second and distributing a third to be carried on concurrently, and enables the machine to run at a speed exceeding that at which any operator can finger the keys. There are a dozen or more models of Linotypes in present use with a wide latitude of accomplishment. The modern models handle all type bodies from 5 point to 36 point, and assemble matrices from all magazines in one line. All machines set from 4 to 30 ems pica measure. Wider measures are obtained by assembling two or more slugs end to end. The later models have many added conveniences, and the larger machines carry two or more simultaneously acting distributors. From one to four interchangeable magazines are supplied with individual machines. Each magazine contains two-letter matrices representing 180 characters. On models 16 and 17, each having two magazines, the mere touching of a key brings either magazine into operation, rendering available 360 characters from one keyboard of 90 keys. In other models an auxiliary magazine is added with keyboard of 28 keys representing 56 characters, making a total of 416 characters in the machine.

The quadruple magazine Linotype carries eight faces, and gives the operator 720 characters from one keyboard. In 1915 the quadruple magazine head-letter machine was brought out for setting newspaper display heads in 48-, 54- or 60-point. It will be apparent that the modern machines can set the great majority of advertising and display composition, as well as the straight body reading matter, to which they were originally confined. Among recent improvements is an electrically heated metal-pot for heating the metal. This not only reduces the nuisance from lead fumes, but permits extremely close regulation of the temperature of the metal. In 1928 there were over 60,000 Linotypes in actual use all over the world.

The Monotype Composing Machine, type-and-rule caster, is so named because it casts each character on a separate body and auto-

matically assembles them into lines and columns ready for the press. The system consists of two separate mechanisms, a keyboard and a casting machine, frequently looked after by one operator. The equipment is arranged to make production continuous, for both keyboard and caster are busy on the same job, but should either be temporarily stopped it does not interfere with the other, which keeps right on producing. The composition is done on the keyboard, which perforates the paper controller ribbon for the casting machine. This keyboard, consisting of 225 keys, has the same arrangement of characters for every alphabet as any standard typewriter. The keys are coupled by means of keybars with valves, which admit air beneath small pistons, which in turn drive the punches through the paper controller ribbon when a key is depressed by the operator. When the key is released, the punches withdraw from the paper and the controller ribbon feeds forward ready to receive the perforations for the next character. The punches are so arranged that certain combinations of perforations across the paper ribbon will position the matrix for the desired character over the mold at the casting machine.

In addition to the key and perforation mechanisms, the keyboard has a counting and justifying mechanism. The counting arrangement counts the width of each character as struck and adds it to the width of the characters previously struck in the line, so that the operator can tell at a glance just how much has been put into the line and how much space still remains. The justifying mechanism consists of a pointer which rises one notch each time the space bar is struck, to put a justifying space between words, and a cylinder (the justifying scale) which revolves automatically when the operator has put sufficient characters and spaces in the line to bring it within four ems of the end of each line. The surface of this scale is divided into small rectangles, each containing numbers which refer to the justification keys on the keybank. The keys corresponding to the two numbers indicated by the pointer are struck by the operator, when sufficient characters have been put in the line, and the perforations produced by these keys set the wedges at the casting machine to produce spaces the correct width to exactly justify the line.

The casting machine is entirely automatic in its operation and is controlled by the controller ribbon perforated at the keyboard. Two hundred and twenty-five matrices are carried in the matrix case; and, for different combinations, characters may be substituted, or the matrix case removed and a new case inserted in the machine. The face of the type is cast in the matrix, but the body of the type is cast in the mold on which the matrix seats while the type is being cast. The type comes out on the casting machine in automatically justified lines, as previously described, and these lines are assembled on an ordinary galley ready for the make-up man. It composes type in any measure up to 60 picas and in sizes from 5- to 24-point; when required, measures up to 120 picas may be composed at the keyboard. The duplex keyboard unit composes simultaneously the same matter in two different faces, point, sizes and measures; the same keystroke that produce the ribbon for magazine columns in 8-point, for example, also produce the ribbon for the same matter in 10-point for book pages, etc.

When operated as a type-and-rule caster, the Monotype casts type for the cases, borders and space material, both high and low, in sizes from 5- to 36-point. An ingenious new unit casts rules and both high and low leads from 2- to 12-point in continuous strips, and automatically cuts them to any required measure from 6 picas to 25 inches in length.

The versatility of the Monotype and the ability to supply practically everything needed in the composing room has made possible the non-distribution system now in use in many newspaper and book and job printing offices. The machine-set matter as well as the hand-set matter, when used, is simply pushed off the imposing stone into the melting pot and recast into new material for every job — type, borders, leads, slugs, etc.— this new method proving more economical than distribution by hand for re-use. The Monotype thus, while a composing machine, also brings to the printing office a practicable, small type foundry which supplies the greater part of the material needed in the composing room.

The Intertype composing machine, introduced in 1913, is manufactured on the expired patents of Ottmar Mergenthaler, combined with many modern improvements. The operator manipulates a keyboard of 90 keys, and matrices are arranged in lines, automatically spread to column measure, and carried to the mold, where a line-slug is automatically cast, while the matrices are returned to their original position by an automatic distributor. Either the matrices supplied by the manufacturer or linotype matrices may be used. One standard machine is built, on the unit principle, to which every improvement can be added by the purchase of more units. Thus the purchaser of a low-priced machine does not have to discard it to secure the conveniences of the higher-priced machines. From one- to three-magazine machines are made, and the one-magazine machine is readily changed into a three-magazine outfit, which will supply 540 characters from the one keyboard. A simple lever movement brings a new magazine to operating position. The Intertype is remarkable for its scientific design and the small number of parts used in its construction; the escapement has only two parts. All Intertypes produce from 5 to 36 point body, and 5 to 30 ems pica measure.

The Linograph machine is manufactured in Davenport, Iowa. It is very similar to the 1900 style of Linotype, plus a number of modern additions. It is designed to supply the needs of the small newspaper desiring a low-priced machine. The Stringer composing-machine supplies a product either in single type or in line-slugs, at the choice of the operator. It was brought out in England in 1914, and is not yet in general use. Several inventors have tried to produce a one-man machine that would cast and set single type at one operation, at a speed commercially profitable. Such a machine is theoretically possible. The Goodson, Wicks, Pierson and other type-casting and setting machines have been developed more or less experimentally, at great expense, but have not found general sale. The Wicks machine cast type at a speed of 60,000 an hour, and was used for some years on a London newspaper.

CHARLES H. COCHRANE,
Of the Staff of Newspaperdom.

COMPOSITÆ (Lat. "compound," "put together"), a family of dicotyledonous plants, the greatest order in the vegetable kingdom, usually herbaceous in temperate and colder climates and shrubby in dry and hot regions, and seldom, apparently only in tropical zones, growing as trees. The leaves are never accompanied by stipules; they most commonly are alternately arranged, and sometimes opposite or whorled. But the true mark of the order is the compound flower, from which it gets its name and which makes it one of the simplest orders to identify, the daisy or aster being the commonest type and the name aster family or sun-flower family being sometimes used. The true blossom is a head made up of many florets, flat as in the aster or approaching a conical shape as in the black-eyed-susan. This head is set in an involucre of leafy bracts, which to the lay observer resemble petals and give the compound flower the appearance of a single bloom. The calyx, joined to the ovaries, crown them, save in a few cases, with the pappus, which is usually hairy, toothed or bristly, and coming to maturity at the time of fruition frequently furnishes the seed with a sort of wing facilitating dispersion by the wind. The corolla, tubular, ligulate or labiate, divides into five lobes at the summit. The anthers are united in a tube by which the five stamens are also joined into one. The ovules at fruition dry up and become achenes (q.v.). Among the florets, which naturally fall into two classes, the fertile ones of the disc and the sterile ones of the ray, grow bracts called paleæ or chaff, except where the receptacle is naked. The classification of the order *Compositæ* is difficult, if for no other reason because it contains about 1,000 genera and more than 11,000 species, that is, about one-tenth of the higher vegetable forms. The simplest division is into *Liguliflora*, with all florets ligulate or strap-shaped, and *Tubuliflorœ*, with disc florets not ligulate. The latter class is by far the larger. The *Liguliflorœ* contains only the one tribe, *Cichorieæ*, often classed as a distinct family, of which the food-plants, lettuce, salsify and chicory, are the best known members. In the other sub-order, the *Tubuliflorœ*, are 12 tribes: *Vernonieæ*, with 41 genera, ironweed being a common member; *Eupatorieæ*, with 35 genera, including the medicinal plants, ayapana, bitterbush, boneset and hemp agrimony; *Astereæ*, including the typical asters, dahlias, etc.; *Heliantheæ*, with the artichokes and other tuberous plants; *Inuleæ*, of which elecampane may be mentioned as an example; *Helenieæ*, sneezeweed being an American member; *Anthemideæ*, including the different varieties of camomile, the chrysanthemum and the marguerite; *Senecioneæ*, with four sub-tribes, and the old-fashioned foliage plant called dusty miller; *Calendulaceæ*, including the marigolds; *Arctotideæ*, with only one genus, occurring in South Africa and Australia; *Mutiseæ*, another scantily diffused tribe; and *Cynareæ*, including the thistles.

The *Compositæ* may be regarded, especially from a consideration of their flowers, as the highest order in a scale of vegetable evolution. Their peculiarly efficacious methods of pollination, this process being simplified by the close set florets which permit of insect-fertilization or wind pollination, and by a peculiar action of the style which in the individual flower pushes itself in the way of wind or insect. Dissemination also is highly developed, there being three prominent types, the plumose pappus, as in dandelion and thistle, which is wind-sown; the hooked achenes, as in the burdock and tickseed, which fastens to passing animals, and the gummy seeds of other plants, which are dispersal adaptations. On the order in general consult Bentham, 'On the Classification, History, and Geographical Distribution of the Compositæ' (1873).

COMPOSITE ORDER, a term denoting the last of the five orders of architecture. As its name implies, it is composed of two orders, the Corinthian and the Ionic. Its capital is a vase with two tiers of acanthus leaves, like the Corinthian; but, instead of stalks, the shoots appear small, and adhere to the vase, bending round toward the middle of the face of the capital; the vase is terminated by a fillet, over which is an astragal crowned by an ovolo. The volutes roll themselves over the ovolo, to meet the tops of the upper row of leaves, whereon they seem to rest. The corners of the abacus are supported by an acanthus leaf bent upward; and the abacus itself resembles that of the Corinthian capital. In detail, the Composite is richer than the Corinthian, but it is less light and delicate in its proportions. Its architrave has only two fasciæ and the cornice varies from the Corinthian in having double modillions. The column is 10 diameters high. The principal ancient examples of this order are the temple of Bacchus at Rome, the arch of Septimius Severus. The Composite order differs from the Corinthian in the design of its capital and in no other way. The capital is made up of the foliage of the Corinthian and the volutes of the Ionic capital. Most of the Byzantine capitals were based on the Roman Composite in its varying forms. The Italians, in their attempts to follow the ancient Roman Composite, have vitiated the true Composite forms, and in this they have been followed by some famous foreign architects, notably by Inigo Jones.

COMPOSITION, in law, an agreement between debtor and creditor or creditors, by which the latter accepts part of the debt due in satisfaction of the whole. Composition also bears the secondary meaning of the sum or rate paid or agreed to be paid in compounding with creditors.

COMPOSITION OF FORCES AND MOTIONS. See MECHANICS.

COMPOST, any mixture of decomposed organic matter with earth, used as a fertilizing compound. A compost is most frequently made by alternating layers of sods and stable manure in piles three or four feet thick and sprinkling them with lime, kainit and some potash salt, such as the sulphate or muriate. After several weeks, during which they are kept moist by applications of water or, better, liquid manure, they are cut with a spade and turned over to form a new heap in which the various substances are mixed as much as possible. They may be turned several times to ensure the decay of the various organic materials. By varying the pro-

portions of manure and fertilizer to soil and organic matter composts may be obtained suitable for various purposes; rich ones for succulent crops and less rich for plants that must be kept stocky. In a general way the term compost is also used for any heap of decaying vegetable or animal matter which is to be used as a manure. Thus stable manure and litter become compost heaps; also the piles of leaves, etc., from which leaf mold is obtained for greenhouse use. Directions for making composts for particular kinds of plants may be found in all books on gardening, floriculture, etc., and many of the works dealing with manures and manuring also devote space to composting. A mixed dish is called a compost or compote; and the term is also applied to a composition for plastering the exterior of houses. In this latter use it is often popularly contracted to compo.

COMPOSTELLA, kŏm-pŏs-tā'lą, **Order of Saint James of,** an order of Spanish knights formed in 1175 to protect from the Moors the Christian pilgrims who had flocked in vast numbers to Santiago de Compostella Galicia, Spain, where the relics of Saint James the Great were preserved. At first there were but 13 members of the order, but it grew rapidly in numbers and they became not only strong defenders of the relics of their patron but champions of Christianity against the invasion of the Moors. In time this order attained great wealth, thereby exciting the jealousy of the Crown, which succeeded in securing the grand-mastership in 1522, after which the order rapidly declined. On the overthrow and expulsion of the Moors from Spain in 1492 the excuse for the existence of the Society ceased, and the following year Ferdinand and Isabel, who then ruled Spain as joint sovereigns, took possession of the abbeys, villages, towns and landed property of the Compostella order and held them until 1522, when a papal bull vested the grand-mastership permanently in the Crown.

COMPOUND ALCOHOL, rectified spirits to which has been added one or more flavoring ingredients. They are called also compounds. The chief compounds are gin, British rum, British brandy, and some grades of American whisky, cordials and liqueurs, such as curaçao, lovage, cherry brandy, noyeau, rum shrub, etc., are also denominated compounds. These are prepared by adding to clean rectified spirits various essences or oils and sweetening with sugar or syrup. Sweetened compounds usually contain from 20 to 35 per cent of proof spirit.

COMPOUND AMMONIAS, or **AMINES,** a large and very important class of complex substances derived from ammonia by replacement of the hydrogen with an organic radical. They are termed primary, secondary or tertiary, according as one-third, two-thirds or the whole of the hydrogen is replaced by an organic radical. They are found in nature in the vegetable alkaloids and among decomposition products of animal and vegetable organisms. They are all basic in function, combining with acids to form crystalline salts. They have an alkaline reaction. Some of the lower members of the group are gases and volatile liquids, generally inflammable, with a pungent fishy odor. As the molecular weight increases they become more stable, and the higher members are solid and odorless. They are of great importance in the investigation of the constitution of various organic bodies. See AMINE.

COMPOUND DUTIES. See DUTY.

COMPOUND LOCOMOTIVES. See LOCOMOTIVE.

COMPOUND STEAM-ENGINE. See STEAM-ENGINE.

COMPOUND WORD. See under GRAMMAR, ENGLISH.

COMPOUNDING A FELONY, the act of accepting from a felon, by the person aggrieved, a return of the goods, a consideration or a reward, on the express condition that he will not prosecute the felon. The mere failure to prosecute a person committing a crime is not, even if the goods are returned, compounding a felony; but the essence of the action is the agreement not to prosecute for a consideration of any kind. It is usually illegal to accept the return of money or goods stolen or to hide or condone other illegal acts performed or procured by the offending party or another, in his interest, upon a promise of immunity from prosecution or the withdrawing of evidence. The person aiding the felon is an accessory to the crime and can be prosecuted, although the person committing the crime has never been tried. In English law, to advertise a reward for the return of stolen goods renders the advertiser liable to a fine.

COMPRESSED AIR. Compressed air has a wide application in the various branches of mechanical engineering and in the arts and manufactures. As compared with steam, compressed air transmission of power is valuable and convenient because (a) its loss in transmission through pipes is relatively small, (b) the question of the disposal of exhaust steam underground is avoided and (c) the exhausted air is a help in ventilation. Although electricity has become a rival of compressed air in many branches of work, their spheres of usefulness are not identical. The first cost of an electric plant is lower than that of an equivalent compressed air plant; but a point is soon reached where compressed air transmission becomes the cheaper. In recent years the principles of air compression have become better understood and a substantial improvement has taken place not only in the design of the compressors themselves, but also in the installation of pipe lines and in the operation of the machines. In the production, transmission and employment of compressed air a greater total efficiency is now realized than was formerly thought possible.

Cooling During Compression.— If air at atmospheric pressure and 60° F. could be compressed to 100 pounds gauge pressure and all the heat due to the work of compression taken away as fast as generated, so that the temperature during compression would remain constant, the mean effective pressure during one stroke of the air piston would be 30.2 pounds. If, on the other hand, none of the heat due to the work of compression was taken away the mean effective pressure during the stroke would be 41.6 pounds and the terminal temperature would reach 485° F. As the power required for compression is directly proportional to the mean effective pressure, it will be seen that the additional power required in the latter case is

37½ per cent. In practice neither extreme is reached, for it is impossible to completely cool the air during compression, and, on the other hand, some of the heat of compression will be radiated; but the lower extreme is the ideal, and the nearer it can be approached the more economical the compressor will do its work.

Heat of Compression.— Various plans for taking away the heat generated in compression, such as injecting a spray of water into the cylinder, circulating cooling water through the piston and around the heads and cylinder barrel, etc., have been tried. The use of the cooling spray, or so-called "wet compression," has long since been abandoned, as has also the plan of circulating water through the piston, for the disadvantages more than offset the advantages. Cylinder heads and barrels are still water-jacketed, not so much on account of the heat that can be taken from the air as to keep the cylinder cool enough for proper lubrication. The most effective means for taking away the heat of compression and reducing the amount of power required consists of dividing the compression into two or more stages, depending upon the terminal pressure, and cooling the air as much as possible between stages by means of suitable cooling apparatus; the water-jacketing of the cylinders being retained for the reason above stated. Where the work of compression is done in two or more cylinders, it is customary to so fix the ratio of cylinder volumes as to divide the work equally between the cylinders. By using two-stage compression and cooling the air between the stages to its initial temperature (60° F.), without considering the cooling by water-jacketing, it is possible to reduce the mean effective pressure to 35.5 pounds as compared to 41.6 pounds, which is equivalent to a saving of 15 per cent. At the same time the terminal temperature will be only 245° F. instead of 485° F.

Clearance.— Another factor in compressor design is the clearance in the compressor cylinders. It is not possible to run a compressor without some space between the piston and cylinder head at the end of the stroke, and in addition to this space there is the volume of the inlet and discharge passages between the valves and cylinder bore. The aim of all compressor builders should be to make this clearance space as small as possible in proportion to the volume swept through by the piston; for at the end of the stroke the clearance space is filled with air at the terminal pressure, which must expand back to the initial pressure before the inlet valve is opened. This is particularly important in single stage compression, as at discharge pressures ordinarily used the expanding of the compressed air in the clearance space back into the cylinder seriously affects the volumetric efficiency of the compressor.

Initial Heating.— The capacity and efficiency of a compressor is also affected by the initial heating of the air. Under ideal conditions the cylinder would, on the suction stroke, be filled with air at full atmospheric pressure and at a temperature no higher than that of the outside air, but such ideal conditions are impossible of attainment. Even with an unobstructed inlet passage air will not flow into the cylinder without some indifference in pressure to force it in, and when, as in many compressors, the inlet valves are of the spring weighted poppet type, this difference as to its effect upon capacity and efficiency becomes a serious matter. Then again, the entering air comes in contact with the cylinder walls, cylinder head, piston and clearance surfaces which have become highly heated during the preceding compression stroke, and is heated thereby to a temperature above that of the surrounding air. This not only reduces the volume of free air at the outside temperature which can be handled, but also raises the terminal temperature of compression.

It is essential to economy in air compression: (1) That the percentage of clearance be kept as small as possible. (2) That the inlet and outlet areas should be large in order to reduce friction losses and heating and to ensure the complete filling of the cylinder at all speeds. (3) That the entering air should pass through short ports, in a solid stream, and over as small an extent of heated surface as possible. (4) That the cylinders and cylinder heads should be water-jacketed in order to take away as much of the heat of compression as possible. To accomplish this as well as to facilitate cleaning, all water spaces and pipes should be large and an ample supply of cooling water used, as cold as can be obtained. Suitable hand holes or openings for cleaning out water spaces should be provided and made use of frequently, and the water should be as clear and free from sediment as possible. (5) That multi-stage compression should be used for anything beyond very moderate pressures.

Hydraulic Compression of Air.— The method of compressing air by means of falling water forms a most interesting topic in the subject of air compression. One of the old forms of compressing air is by means of a trompe or water bellows. Many improvements have been made on this early apparatus and distinct types developed from it, prominent among which are the Frizell, Baloche, Krahnass, Taylor and Arthur devices. There are several phenomena in connection with hydraulic air compression that at first sight seem paradoxical. In compressing air by hydraulic means, the air becomes drier during the compression, but whatever may be its initial condition as to humidity at the end of compression it will be saturated with moisture. Again isothermal compression is secured and, generally speaking, at uniform temperature a given *volume* of air implies a capacity for a certain weight of water whether the air is at a pressure of one or 100 atmospheres, but if the air is compressed through a range from one to 100 atmospheres, its volume will be reduced, if the compression is isothermal, to 1/100 part of the original volume, and in consequence 99/100 of the weight of moisture it originally held will be precipitated. In connection with this type of compressor it has been found that the compressor air contains less oxygen than the free air of the atmosphere and in consequence its use in mines is not as beneficial as air from other types of compressors. The losses inherent in hydraulic compression are: (1) The heat expended in impregnating the water with air; (2) a loss which may be called the slip due to the velocity with which the bubbles tend to rise; (3) a loss due to the increasing solution of the air in the water with the increasing pressure as the water and air descend.

Multi-Stage Compression.— It frequently happens that high pressures are demanded for commercial purposes, and in order to satisfy this demand, avoid the danger of explosion due to high temperatures and reduce the losses due to adiabatic compression, engineers have adopted a multi-stage system of compression — compressing the air partly in one cylinder, passing it through an intercooler where its temperature and volume are reduced, then compressing it still further in a second cylinder, and, if the pressures required are high, this compressed air is passed to a second intercooler, thence to a third cylinder and in some cases a third intercooler and a fourth cylinder, and required to secure the desired compression pressure economically. The advantages of this system of compression more than offset the extra expense in constructing the compressor. The larger the volume of the intercooler, the more time is required for the compressed air to cool; for this reason *receiver intercoolers,* as they are termed, are more efficient than those of small volumetric capacity. See AERODYNAMICS; AIR PUMP; CONDENSER; POWER, UTILIZATION OF.

COMPRESSED GASES. See GASES, COMPRESSED; LIQUEFIED AND COMPRESSED GASES.

COMPROMISE OF 1820, in American political history, a national law enacted by Congress 6 March 1820. In 1819 the Territory of Missouri, with a population of 60,000, demanded admission into the Union as a slave State. Arkansas was preparing to make similar demands. Such action would have given the South the balance of power in Congress, and the North made this a national issue. The North controlled the House of Representatives, while the South controlled the Senate. A deadlock was inevitable, and a party of compromise sprang up, which succeeded in producing a temporary arrangement acceptable to both parties. This was the compromise of 1820. It divided the Louisiana Purchase between freedom and slavery by a line drawn at 36° 30′ N. lat. See UNITED STATES — ABOLITION AND THE FREE SOIL MOVEMENT.

COMPROMISE OF 1833, Henry Clay's tariff compromise, to prevent civil war on account of nullification by South Carolina. The tariff of 1828 was regarded by the South as injurious and inequitable, raising its expenses and reducing its income, and laying burdens upon it without compensating advantages. The tariff was borne in the hope that Jackson, a Southern man, would throw his influence against it, but when he signed the amended act of 1832, leaving the duties much as they were, South Carolina took the lead in revolt. On 19 Nov. 1832, a convention called by its legislature declared the act of 1828 and its amendments null and void, forbade its enforcement in the State or appeal to the Supreme Court regarding it, and decreed secession in case the United States should attempt to use force. On 4 Dec. 1832, Jackson's annual message mildly criticised the tariff as overgrown and needing gradual retrenchment to a revenue basis, and apologized for the popular resistance, which he thought the laws adequate to suppress. The nullifiers and their opponents alike thought he had surrendered to the former as in the Cherokee case (see CHEROKEE NATION *v.* GEORGIA); but on the 10th, apparently from a sudden shift of emotional feeling, he issued a powerful proclamation against them, characterizing nullification as an absurdity "incompatible with the existence of the Union," and declaring that it would be resisted by the entire national force. There was great enthusiasm throughout the North, and general approval even in the South, but South Carolina returned a defiant counter-proclamation, and Calhoun resigned the Vice-Presidency, to be immediately returned to the Senate as the champion of nullification. To remove the grievance the House Committee of Ways and Means on the 27th reported the Verplanck Bill, reducing the tariff within two years to the standard of 1816, the primitive basis. But the President, angered by the new South Carolina threat, asked for a bill to enforce the law by military power, and extend Federal jurisdiction over revenue cases — called by the people the Force Bill, and by the South Carolinians the "Bloody Bill." All parties were perplexed and unable to act. South Carolina had relied on Southern support, which was not forthcoming; the House could not agree on the Verplanck Bill nor the Senate on the Force Bill. On 12 February, 20 days before the final adjournment of the 22d Congress, Clay undertook a compromise. He introduced a bill into the Senate which reduced the duties to a general 20 per cent by a sliding scale to end in 1842, enlarged the free list, etc. Clay's assigned motive was, that without some such measure the protective system was likely to be abolished altogether, but not before there had been civil war, in which the South would not let South Carolina stand alone. A further motive was, that he dreaded to see Jackson made a virtual dictator with a large army in his hands, as none could tell what he might do with it. Calhoun struck hands with Clay, though the pending Verplanck Bill was a far greater relief to the South. But Calhoun was far more anxious for a triumph of nullification and the consequent mastery by the South of her own destinies, than, for mere lightening of material burdens, and the compromise bill would be notoriously a concession wrung from the North by the threat of nullification while the Verplanck Bill, even if passed (which was dubious), would be only a bill like any other. The compromise bill was referred to a select committee with Clay for chairman. The manufacturers' lobby insisted on amendments, of which the chief was very obnoxious to the South — that for computing ad valorem duties on the basis of valuation at the home ports. As they made this an ultimatum, Clay supported it in the Senate, while Calhoun denounced it as both oppressive to the South and unconstitutional. Finally Clayton of Delaware, a strong Protectionist, threatened for his party to lay the whole on the table unless the Calhounists and their leader voted for the amendment, which they did. Meantime the Force Bill had passed the Senate; and Clay urged it to pass the compromise tariff bill also, so that the bill for violence should have that for harmony to counteract it. The objection was raised that the bill was one to raise revenue, and could not

originate in the Senate. This was met by the shrewd device of moving the House to strike out all but the enacting clause of the Verplanck Bill and substitute Clay's bill, and send it to the Senate for concurrence, — which it did the next day, and the Senate adopted it. South Carolina, which had appointed 1 February for the nullification ordinance to go into effect, repealed it, and the country hailed it as a great deliverance. Clay himself later confessed, however, that he doubted whether he had done wisely. The nullifiers denied that they had abandoned a jot of their contention; hailed the result as a proof that it was the only means by which the South could obtain justice; and professed to have postponed the date of its operation only out of friendship to Virginia, which sent a commissioner to deprecate it. It is certain that the South won both the material and the moral fruits of the victory. Consult Schurz, 'Life of Henry Clay' (Vol. II, Chap. 14); also other lives of Clay and biographies of Jackson and Calhoun.

COMPROMISE OF 1850. The Missouri Compromise of 1820 (q.v.) had divided the Louisiana Purchase between free and slave territory at 36° 30′ (the general boundary between Arkansas and Missouri), except that Missouri was to be slave. The extreme pro-slavery members, about one-fifth of the House and one-fourth of the Senate, based their opposition on the ground that Congress had no power to legislate on slaveholding in the Territories, it being a fundamental right implied in the Constitution; but the majority admitted the jurisdiction by passing the bill. The joint resolution for admitting Texas in 1845 extended the same line to any new bodies formed out of that State; and was supported by the most ultra slavery men, as taking the merest sliver from them and securing solidly the enormous remainder. When the Mexican War seemed likely to add new territory, the Wilmot Proviso (q.v.) of 8 Aug. 1846, attempted to bar slaveholding from it, as did existing Mexican law; and the struggle to prevent this transformed political parties. After the annexation had taken place, 2 Feb. 1848, bills for organizing the Territories of New Mexico and California were introduced: at first in an omnibus bill with Oregon (the Clayton Compromise), to force all of them to permit slaveholding; then to extend the Missouri compromise line to the Pacific (including in slave territory nearly all the present New Mexico and Arizona and the entire southern half of California); then the Democratic Senate receded from the Oregon «hold-up,» and the House repeatedly attempted to organize the other bodies as territories with the proviso; while the Senate regularly killed the bills, and once attempted to attach its own as rider to an appropriation bill. This went on till the end of 1849, when the gold discoveries in California forced the hand of both the Southern slavery party and its Northern allies. The immense immigrant population there formed a constitution prohibiting slavery and demanded admission of California as a State. Even the deniers of the right of Congress to legislate on slavery had always admitted that the people of a State had the right to live under any constitution they pleased; and the Democrats, to hold their vote in North and South, now took the position that the inhabitants of an inchoate State should be allowed to decide their own destinies. As this meant the immediate reinforcement and ultimate supremacy of the free States, the Southern Whigs and Democrats began to draw together and formulated the doctrine that the people of a Territory had no right to exclude the industrial or social system of any part of the Union; that Congress should force them to rescind such exclusion if made; and that the exclusion, if permitted, was a wrong which justified secession. But California was not a Territory: it was a body of unorganized settlers who would come in as a State from the first, and certainly could be admitted by Congress on their own terms. The Southern leaders, therefore, resolved that they should not be admitted except by passing through the territorial stage, so as to come under the congressional prohibition. Zachary Taylor, a slaveholder, but a moderate and just-minded man, had been inaugurated as President in March 1849, and his first Congress met in December. The Senate had a large Democratic majority; the House was so evenly divided that the few Free-Soilers held the balance, and it required 63 ballots and three weeks to elect a speaker, Howell Cobb, of Georgia. On their meeting Taylor had sent a message recommending California's wish to become a State, to their favorable consideration; on 21 Jan. 1850, he sent a special message, declaring that the people would not sustain them in denying the Californians the right of self-government. The South, nevertheless, was passionately determined not to yield; and Henry Clay undertook one of the great compromises which were the pride of his life, the shortest-lived and most destructive compromise in American history. The difficulty was to find anything that either side wanted badly enough to take as a price for yielding. For the South, this was found in the Fugitive Slave Law (q.v.), which Alexander H. Stephens declared to be the very essence and heart of the whole compromise and the breach of which by the Northern personal-liberty laws was accounted the crowning justification of secession; and in a money indemnity to Texas for abandoning her claim to the Rio Grande as a western boundary, which that State was ready to fight for, but the payment for which would raise the market value of her bonds, largely held in the South. For the North, it was found in the admission of California as a free State and the prohibition of the slave-trade in the District of Columbia — the latter a mere sop, as slavery was not abolished in the District. The sacrifices were, that the South gave up the right of insisting that no free State should be admitted into the Union except as paired with a slave State, and so in her own view gave the North the fruits of the Mexican War; the North gave up the proviso and the right of stopping the interstate slave trade, though this was later stricken out. On 16 January a bill had been brought into the Senate to organize «the Territories of California, Deseret [Utah], and New Mexico»; on the 29th Clay unfolded his compromise, in eight resolutions: (1) admitting California with her free-State Constitution; (2) organizing the remainder of the newly acquired lands as territories, without restriction as to slavery, as it «did not exist [there] by law, and was not likely to be introduced,» — merely staving off

the question till they formed State governments; (3, 4) annulling Texas' claim to New Mexico, but paying her a blank indemnity; (5, 6) non-abolition of slavery in the District of Columbia without the consent of Maryland, but prohibition of the slave trade in it; (7) a more effectual fugitive slave law; (8) non-interference with the interstate slave trade. Clay said that the question with the South was one of interests, with the North one of sentiment, and the latter was easier to sacrifice than the former. The Northern members and their constituents did not agree to this, nor did the South as to the equivalents; and after two months' debate the question was referred to a compromise committee of 13, of which Clay was chairman. On 8 May it reported a bill of four parts, known in history as the Omnibus Bill (*par excellence*, for there have been others), to be passed or rejected as a whole. The essential changes were, that New Mexico and Utah were forbidden to pass laws respecting slavery, that California should not be admitted unless this were granted, that the blank for the Texas indemnity should be filled with $10,000,000 and that no mention was made of the interstate slave trade. It will be observed that the gains in this revised "compromise" were pretty much all by the South. The bill of course embodied the specific legislation needed to make the resolutions effective. Part 1 consisted of the provisions for admitting California, New Mexico and Utah, and indemnifying Texas; parts 2 and 3 were the Fugitive Slave Law of history; part 4 the provisions about the District of Columbia. This bill was stormily debated for nearly three months more, until 31 July, and amended until one item only was left, that admitting Utah, which passed the next day. Meantime Texas was arming and threatening war, and other States proposing to aid it; and Congress saw that the bills must be passed in some shape. The items were therefore voted on as separate bills, and all passed in Clay's form: Texas bill — Senate, 10 August, 30 to 20; House, 4 September, 108 to 97. California — Senate, 13 August, 34 to 18; House, 7 September, 150 to 56. New Mexico — Senate, 14 August, 27 to 10; House (together with the Texas bill), 4 September, 108 to 97. Fugitive Slave Bill — Senate, 23 August, 27 to 12; House, 12 September, 109 to 75; District of Columbia — Senate, 14 September, 33 to 19; House, 17 September, 124 to 47. The Fugitive Slave Law, the vital part of the compromise, was also its assured ruin, as it gradually turned the entire North into abolitionists; but the immediate cause of its collapse was the Kansas-Nebraska Bill (q.v.), which repealed not only the Missouri Compromise, but the present compromise which practically reaffirmed that. Consult Von Holst, 'Constitutional History of the United States' (Vol. III); Benton, 'Debates of Congress'; Stephens, 'War between the States' (Vol. II); and lives of Clay.

COMPROMISES OF THE CONSTITUTION. See CONSTITUTION, FORMATION OF THE.

COMPSOGNATHUS, kŏmp-sŏg-nā'thŭs, a genus of extinct reptiles of carnivorous dinosaurs (see DINOSAURIA) of the Jurassic Period, of very small size, hardly larger than a domestic cat, and slenderly proportioned. A very perfectly preserved skeleton has been found in the lithographic limestone of Solenhofen in Bavaria. It is remarkable as being the most bird-like reptile known. It had a light, bird-like head, very long neck and hind limbs, small forelimbs and many teeth. It is supposed to have walked or hopped in an erect or semi-erect position just as a bird does. In this position it must have resembled a bird very much.

COMPTOMETER, compt-ŏm'ĕ-ter (from Fr. *compter*, to count + Gr. *meter*, a measure), an adding and calculating machine, on which can be performed rapidly and accurately all arithmetical problems involving addition, multiplication, division and subtraction. The name was coined by Dorr E. Felt, inventor of the machine, in 1885. The comptometer is now widely used on all forms of figure work in all lines of business in the United States and throughout the world. It differs from all the earlier constructive efforts directed to the production of mechanical calculating devices in that it was the first successful multiple-order machine to be wholly operated by the rapid depression of keys, an advantageous feature as a time-saving factor. Illustrative of the fundamental principle of direct key operation and its simplicity in practice are the following brief descriptions of how the results are obtained.

Comptometer

Addition is performed by merely depressing the keys according to the numbers to be added. The item 346, for example, is added by striking the 3-key in the third or hundredths column, the 4-key in the second or tens column and the 6-key in the first or unit column, and the answer appears in the register. Subsequent items are added in the same manner, the accumulated total being shown in the register. To multiply, the fingers are placed on the keys representing one factor, which are struck according to the digits of the other factor. For example, to multiply 578 by 463, place the fingers on 578 and strike three times; move one column to the left and strike six times; once more to the left and strike four times and the register shows 267,614. Each key also bears on its top a small figure which indicates the power of that key for subtracting and dividing. These operations are the converse of adding and multiplying and

are likewise performed by simply depressing the keys, but with reference to the small figures on the keytops. The only function of the lever at the side of the machine is to zeroize or cancel the answer registered preparatory to the beginning of a new operation. In its commercial application, the use of the comptometer extends in a practical way to all arithmetical calculations of accounting, including additions; extending and footing of invoices, inventory, payrolls, estimates; making engineering, astronomical and scientific calculations; in all of which, fractions decimally expressed, are as easily handled as whole numbers. Provision for the addition of common fractions is made by inclusion in the keyboard of a special fractional column or columns. By this means fractional values are automatically accumulated and carried forward in progressive order from the lower to the next higher denomination. To meet special requirements, such as the adding of fractional denominations of foreign currency of various kinds, the different unit divisions of weights and measures, and special uses in the various departments of commercial accounting, suitable combinations of fractional columns are employed. Thus the pounds, shillings, pence and farthings comptometer, widely used in England and other parts of the British Dominion for adding British currency, is provided with fractional columns of 20ths, 12ths and 4ths. In a similar manner a model with fractional columns to 12ths and 16ths serves for adding British-Indian currency, consisting of rupees, annas and pies. 12 pies = 1 anna, and 16 annas = 1 rupee. Another model supplied with fractional columns to 40ths is used for adding funts and poods, the Russian measure of weight, in which 40 funts = 1 pood. A combination designed for the use of contractors, engineers and architects has columns for 12ths and 16ths which facilitate the adding of feet, inches and fractions of inches. Fractions in 60ths are provided for adding hours and minutes; and double 60ths for adding hours, degrees, minutes and seconds in the compilation of astronomical and geographical data. The formation of many other combinations is possible on the comptometer.

Mechanical arithmetic, as practiced on the comptometer, being universal in its scope, constitutes in itself a complete system of mathematics.

COMPTON, Arthur Holly, American physicist: b. Wooster, Ohio, Sept. 10, 1892. He received his B.S. degree from the College of Wooster (1913), his M.A. degree (1914) and his Ph.D. degree (1916) from Princeton University, and worked at the Cavendish Laboratory, Cambridge University, from 1919–1920. He has taught at the College of Wooster (1910–1912); Princeton (1915–1916); the University of Minnesota (1916–1917); Washington University, St. Louis (1920–1923); and the University of Chicago, where he became professor of physics in 1923, and chairman of the department of physics and dean of the division of physical sciences in 1940. He has also held visiting lectureships at Punjab University, India (1926–1927); Oxford University (1934–1935); and the University of Washington, Seattle (1940). In 1945, he was made chancellor of Washington University in St. Louis. Appointed head of the Metallurgical Laboratory, University of Chicago, in 1942, he directed research on plutonium for the atomic bomb project. His scientific work has been concerned with X-rays, photons, and gamma rays. He discovered the change in wave length occurring with scattered X-rays, a phenomenon known as the Compton effect, for which he received the Nobel Prize in physics in 1927, jointly with Charles T. R. Wilson, of England. He has also been interested in cosmic rays, directing a world survey of this subject, 1931–1933. He wrote *X-rays in Theory and Experiment,* in collaboration with Samuel K. Allison (1935).

COMPTON, Henry, English bishop: b. Compton Wynyates, Warwickshire, 1632; d. Fulham, July 7, 1713. He was the youngest son of Spencer, 2d Earl of Northampton, studied at Oxford, and after the Restoration became a cornet in a regiment of horse. After he left the army for the Church, he became bishop of Oxford in 1674, and bishop of London in 1675. Charles II made him a member of his privy council, and entrusted to him the education of his nieces Mary and Anne. He was distinguished for his hostility to the Roman Catholic Church. After the accession of James II, Dr. Sharp, rector of Saint-Giles-in-the-Fields, having become highly obnoxious to the court, Compton was required by a royal order to suspend him. His refusal to obey was made the ground of his own suspension. He was restored to his see at the Revolution of 1688, and, together with the bishop of Bristol, made up the majority of two in the House of Lords for filling the vacant throne. He performed the ceremony of the coronation of William and Mary, and was afterward appointed one of the commissioners for revising the liturgy. During the reign of Anne he was put on the commission for the union of England and Scotland.

COMPTON, Calif., city in Los Angeles County; altitude 67 feet; 10 miles south of Los Angeles; has varied industries; fine public buildings; junior college. Pop. (1940) 16,198.

COMPTON EFFECT, The. See QUANTUM THEORY—*The Compton Effect.*

COMPTROLLER, State. An officer—sometimes an auditor—directly responsible to the legislature, who sees that all legal requirements for the payment of State funds are complied with, that claims are valid, that the payment of same have been authorized and that the funds have been appropriated and are available, whereupon bills are paid on his warrant. He supervises the State finances to the extent also of compelling clearness, accuracy and completeness in the accounts, the indication of all receipts and the legality of all disbursements.

COMPTROLLER OF THE CURRENCY, the chief officer of a bureau of the Treasury Department. He performs his duties under the general directions of the Secretary of the Treasury. Under the general supervision of the Board of Governors of the Federal Reserve System, he is charged with the execution of all laws relating to the issue and regulation of Federal Reserve notes.

The Comptroller exercises supervision over national banks through an office and field force of about 1,300, and has charge of the liquidation of national banks for which receivers have been appointed, through an additional office and field force of about 1,900. He renders an annual report to Congress containing a summary of the state and condition of every national bank and a

statement showing the resources and liabilities of all banks in the country. The report, in addition, contains information of a statistical nature regarding the affairs of national banks and the Comptroller's recommendations to Congress for amendments to the national banking laws. The salary of the Comptroller is $15,000 per annum. He is appointed by the President of the United States by and with the advice and consent of the Senate for a term of five years.

COMPTROLLER GENERAL OF THE UNITED STATES. The offices of Comptroller General of the United States and Assistant Comptroller General of the United States were created by an act of Congress known as the Budget and Accounting Act, 1921, which was approved by the President 10 June 1921 (42 Stat. 23). The Comptroller General of the United States and the Assistant Comptroller General are appointed by the President with the advice and consent of the Senate, hold office for 15 years but not after attaining the age of 70 years, and are removable for cause by joint resolution of the Congress. The Comptroller General is not eligible for reappointment. The Comptroller General receives a salary of $10,000 per annum. The Assistant Comptroller General receives a salary of $9,000 per annum (Classification Act of 1923, as amended).

Effective 1 July 1921, the Budget and Accounting Act, 1921, abolished the office of Comptroller of the Treasury, which had been in effect since 1789, the office of Assistant Comptroller of the Treasury, and the offices of the six auditors of the Treasury Department, and created a new independent Government establishment, the General Accounting Office, under the control and direction of the Comptroller General of the United States. The Comptroller General of the United States as head of the General Accounting Office is vested with substantially all powers and duties previously conferred or imposed by law upon the former Comptroller of the Treasury and the six auditors of the Treasury Department, as stated in the Act of 31 July 1894 (28 Stat. 208) and other statutes extending back to the original Treasury Act of 2 Sept. 1789 (1 Stat. 65), together with other specific powers and duties imposed by the Budget and Accounting Act, 1921, and by subsequent legislation. The purpose in creating the General Accounting Office was to secure, independent of the executive departments and other spending and collecting agencies of the Government, the uniform settlement and adjustment of all claims and accounts in which the United States is concerned, either as debtor or creditor, that accounts against the Government conform to law and that payment of the same has been authorized by statute.

R. N. Elliott,
Acting Comptroller General of the United States.

COMPULSORY EDUCATION. See Education, Compulsory.

COMPULSORY HEALTH INSURANCE. See Social Insurance.

COMPULSORY VOTING. See Vote; Voters; Voting.

COMPURGATION, a mode of defense allowed by the Anglo-Saxon law in England, and common to most of the Teutonic tribes. The accused was permitted to call a certain number of men (usually 12), called compurgators, who joined their oaths to his in testimony to his innocence. They were persons taken from the neighborhood, or otherwise known to the accused, and acted rather in the character of jurymen than that of witnesses, for they swore to their belief, not to what they knew; that is, on the accused making oath of his innocence, they swore that they believed he was speaking the truth. Compurgation in the ecclesiastical courts was not abolished till the reign of Elizabeth and it was used in some civil cases as late as 1833. The Assize of Clarendon, 1166, is credited with helping strongly to the doing away with compurgation in the King's Courts as a mode of trial for crime.

COMPUTING SCALES, instruments by which the value is obtained, mechanically, at a given price per pound or kilo, thus avoiding any error of making the calculations mentally, and causing the operation of weighing and ascertaining the value to be more speedily accomplished.

The computing-scale business, as a successful commercial enterprise for the world, was inaugurated in 1891.

Construction of Computing Scales.— Broadly speaking, there are two types of computing scales: first, the variable leverage type, and second, the computed-chart type. The first type consists of a mechanism wherein the leverage of the computing beam may be varied so as to conform to the several units per pound or price per pound.

The computed-chart scale is further divided into two distinct kinds: first, the beam scale with computed chart, and second, the automatic scale with the computed chart. The former, or beam scale with computed chart, is a manually-operated scale, operated as in ordinary scales by the movement of a sliding counterpoise, this sliding poise passing over the computed chart, and when the load is balanced by the movement of the poise, pointers on the poise indicate the total value of the commodity being weighed at the several prices per pound provided for on the computed chart.

The second, or automatic computing-chart scales, are so constructed that when a commodity is placed upon the scale pan the load is automatically counterbalanced by the use of either counterbalancing springs or a pendulum counterbalancing weight, moving either the computed chart past a stationary indicator or moving an indicator past or over the stationary computed chart, the indicator in either instance having placed thereon the several prices per pound, and each price per pound placed adjacent to a pointer or other means of indication showing the total value of the commodity being weighed at the several prices per pound provided for in the construction of the scale.

The automatic-chart scale is further divided into two distinct types of scales with respect to the construction or arrangement of the chart: One type being constructed upon the principle of arbitrarily dividing the pound into as many parts as there are cents in the price per pound as a means of computing weight. For instance, at 11 cents per pound the pound is divided into 11 parts, each part representing one-eleventh of

a pound. The other type is constructed on the principle of dividing the pound into ounces and fractions of ounces on the binary system as a means of computing values. In other words the pound is divided into uniform fractions of the pound as in ordinary pound and ounce scales, and the true commercial value of each subdivision of the pound is indicated on the chart at the several prices per pound provided therefor. See BALANCE; WEIGHING MACHINES.

COMSTOCK, Anna (BOTSFORD), American naturalist and engraver: b. Otto, N. Y., 1 Sept. 1854; d. Ithaca, N. Y., 24 Aug. 1930. After graduation from Chamberlain Institute, Randolph, N. Y., in 1873, and from Cornell University in 1878, she studied art at the Cooper Union, New York city, and under John P. Davis. In 1899 she was appointed assistant professor of nature study Cornell University extension work, 1899–1900 lecturer; Leland Stanford Junior University extension work; assistant professor of nature study, Cornell 1913–20; professor 1920–22. She was awarded the bronze medal for wood engraving at the Pan-American Exposition of 1901. She published 'Problems of the Six-Footed'; 'How to Keep Bees' (1904); 'Confessions to a Heathen Idol' (1906); 'Handbook of Nature Study' (1911); 'The Pet Book' (1914); 'Bird, Tree, and Plant Notebooks' (1914). Editor *Nature Study Review* 1917–23.

COMSTOCK, Anthony, American reformer: b. New Canaan, Conn., 7 March 1844; d. New York, 21 Sept. 1915. In 1863 he enlisted in the 17th Connecticut regiment, served under General Gilmore and was mustered out in July 1865. In March 1873 he became secretary and special agent of the New York Society for the Suppression of Vice and completely identified himself with its work. It is said that largely through his special efforts 2,500 criminals were brought to justice and over 80 tons of indecent literature and pictures seized and destroyed. He wrote 'Frauds Exposed; How the People are Deceived . . . and Youth Corrupted' (1880), an exposure of various schemes operated through the mails; 'Traps for the Young' (1883); 'Gambling Outrages; or, Improving the Breed of Horses at the Expense of the Public Morals' (1887); 'Morals Versus Art' (1887); and minor tracts for the furtherance of his work.

COMSTOCK, George Cary, American astronomer: b. Madison, Wis., 12 Feb. 1855. He was graduated at the University of Michigan 1877 and from the law department of the University of Wisconsin 1883; devoted himself entirely to astronomy and from 1887 to 1922 was professor of that subject and director of the Washburn Observatory, University of Wisconsin; dean graduate school 1906–20; member, National Academy of Sciences. Publications: 'Text-Book of Astronomy' (1901); 'Field Astronomy for Engineers' (1902); 'Method of Least Squares' (1890); 'The Sumner Line as an Aid to Navigation' (1919), and numerous papers upon astronomical subjects. D. 11 May 1934.

COMSTOCK, Harriet Theresa (SMITH), American author: b. Nichols, N. Y., 1860. She was educated in public schools and in the academy at Plainfield, N. J. She married Mr. Philip Comstock in 1885. Since 1895 she has become known as a prolific writer of juvenile stories and is author of 'Molly, the Drummer Boy' (1900); 'Cedric the Saxon' (1901); 'A Boy of a Thousand Years Ago' (1902); 'A Little Dusky Hero' (1902); 'Tower or Throne' (1902); 'When the British Came' (1907); 'The Queen's Hostage' (1907); 'Janet of the Dunes' (1912); 'Joyce of the North Woods' (1913); 'The Place Beyond the Winds' (1915); 'The Vindication' (1916); 'The Tenth Woman' (1923); 'Piper's Price' (1929), etc.

COMSTOCK, John Henry, American entomologist: b. Janesville, Wis., 24 Feb. 1849; d. Ithaca, N. Y., 20 Mar. 1931. He was graduated from Cornell University, 1874; served as U. S. entomologist at Washington, 1879–81, and as professor of entomology and general invertebrate zoology at Cornell, 1881–1914; professor emeritus thereafter. His investigations dealt with the morphology, classification and economic relations of insects. His wife, Anna Botsford Comstock (q.v.), assisted him. He was a constant contributor to the literature of his subject, the following being the more important of his works in book form: 'Report on Cotton Insects' (1879); 'Introduction to Entomology' (1888); 'Manual for the Study of Insects'; 'Insect Life' (new ed., 1901); 'Elements of Insect Anatomy' (3d ed., 1903, with Kellogg); 'How to Know the Butterflies' (with his wife, 1904); 'The Spider Book' (1912); 'The Wings of Insects' (1897).

COMSTOCK, John Lee, American writer on physics: b. Lyme, Conn., 1789; d. Hartford, Conn., 21 Nov. 1858. He received a common-school education, studied medicine and during the War of 1812 was assistant surgeon at Fort Trumbull, Conn., and on the Northern frontier. He settled in Hartford, Conn., practised medicine until 1830, when he became an author by profession and attained remarkable success in the compilation of textbooks for educational purposes. His 'Introduction to Mineralogy' (1832) was used at West Point; of the 'Elements of Chemistry' over 250,000 copies were sold; while the 'System of Natural Philosophy' (1831) had a sale of over 900,000 copies (94th ed., New York 1847) and was translated into the chief European languages. Others were 'History of the Greek Revolution' (1828); 'History of the Precious Metals' (1849); 'Natural History of Quadrupeds' (1829); 'Grammar of Chemistry' (1825); 'Introduction to Botany' (3d ed., 1835).

COMSTOCK, Theodore Bryant, American geologist: b. Cuyahoga Falls, Ohio, 27 July 1849; d. 26 July 1915. He was graduated at Pennsylvania State College 1868, and at Cornell 1870, where he was professor of economic geology 1875–79. In 1873 he was geologist to Capt. W. A. Jones' Wyoming and Yellowstone Park expedition and accompanied Hartt's expedition to Brazil 1870. He was professor of mining engineering and physics in the University of Illinois 1885–89, and assistant State geologist of Arkansas 1887–88, and of Texas 1889–91. He founded the Arizona School of Mines, was its director 1891–95, and president of the University of Arizona 1893–95. He was at various times engaged as manager, engineer and consulting expert to many mining companies and syndicates, both American and foreign. He published 'Outline of General Geology' (1878); 'Classification of Rocks' (1877);

'Notes on the Geology of the San Juan Country' (1882); 'The Geology and Vein Structure of Southwestern Colorado' (1886); the last two in the 'Transactions' of the American Institute of Mining Engineers; and numerous papers in the *American Journal of Science, American Naturalist and Engineering and Mining Journal.*

COMSTOCK LODE, a remarkable vein near Virginia City, Nev., carrying silver sulphides with some native silver and considerable native gold. The wide vein is a faulted fissure following the contact of a basaltic dike with the andesite country rock, the latter of Tertiary Age. The gangue is mainly quartz. The ores are of recent origin, and the waters ascending along the fissure are hot, making mining costly. Some wonderfully rich ore bodies, «bonanzas,» were found in certain of the mines along the lode, and the history of its discovery, the great mining speculations based on it, and the final abandonment of nearly all the mines, reads like a romance. The names of Fair, Flood, Mackay and O'Brien are connected with it. The total yield of the lode from its discovery in 1859 up to 1890 was over $340,000,000; the greatest yield for a single year was $38,000,000 in 1877. The yield has declined since 1890. The Comstock Lode had been of great interest to scientists. In 1868 Von Richthofen studied here the geologic relations of the ore bodies and Van Hise, Becker and others evolved the modern classification of igneous rocks through their studies of the formations here. Barus conducted experiments here to determine temperature variations at different depths. Consult Becker, «Geology of the Comstock Lode and Washoe District,» (in 'Monograph of the United States Geological Survey,' Vol. III, Washington 1882); Lord, «Comstock Mining and Miners,» (in 'Monograph of the United States Geological Survey,' Vol. IV, ib. 1883); Reid, 'Structure and Genesis of the Comstock Lode' (Berkeley, Cal., 1905).

COMTE, kônt, **Isidore Auguste Marie François Xavier,** generally known as AUGUSTE COMTE, a famous French philosopher: b. Montpellier, 19 Jan. 1798, of a strict Catholic family; d. Paris, 5 Sept. 1857. He was very precocious in his intellectual development; in his own words, at the age of 14 he went through all the necessary stages of the revolutionary tendency, and felt the necessity of a general political and religious rebirth. In 1814 he entered the École Polytechnique at Paris. Though the school was broken up by the government in 1816 for political reasons, Comte remained in Paris and developed a close acquaintance with Saint Simon (q.v.), from whom he learned the need of substituting a new spiritual power for the mediæval hierarchy in Church and State. However, a breach developed between these two men, dating from the publication of Comte's «Plan des travaux scientifiques necessaires pour réorganizer la société,» which found the greatest hindrance to the development of society in the continued ascendancy of the revolutionary tendency. In 1825 he married Caroline Massin, but the marriage was unfortunate from the start. The following year he began to lecture on philosophy at his own house, but after his first few lectures he was struck down by an attack of insanity, which resulted in an attempt at suicide. This proved to be temporary, however, and in 1828 he was again able to carry on his intellectual labors and his lectures. In 1832 he became tutor in mathematics at the École Polytechnique, and in 1837 examiner at the same institution. He also engaged in secondary-school teaching. He held the post of examiner for some 10 years, but incurred the displeasure of his colleagues by some reflections on mathematics and lost the position. His British disciples, including among others Grote and J. S. Mill (q.v.) then supported him, sending him $1,200 in 1845. For the rest of his life he lived on the proceeds of a public subscription initiated by Littré in 1848. He was separated from his wife since 1842, and in 1845 he met Clotilde de Vaux, whose husband was serving a life sentence. He became excessively fond of her, and after her death the following year had another, though a less serious, attack of mental aberration.

Besides the book already named Comte wrote 'Cours de philosophie positive'; 'Discours sur l'esprit positif'; 'Calendrier positiviste'; 'Système de politique positive'; 'Bibliothèque positiviste'; 'Catéchisme positiviste'; 'Appel aux conservateurs, par le fondateur du positivisme'; 'Synthèse subjective'; 'Système de logique positive.' Comte believed that knowledge passed through three stages of development, the *theological* stage, in which the imagination plays the greatest part in giving accounts of things. The *metaphysical* stage, in which abstract principles replace the imaginary deities of the theology, and in which the tendency to unification takes the lead; and the *positive* stage, where both imagination and argumentation are subordinated to observation, and agreement with the facts becomes the ultimate scientific criterion. The facts arrange themselves in certain irreducible groupings, which are at least as many as there are distinct sciences, so that the unity of knowledge is subjective, not objective. These sciences Comte classifies according to the order in which they have reached their positive stage, as follows: mathematics, astronomy, physics, chemistry, biology, sociology. This order is also the decreasing order of broadness of scope in the sciences concerned and the order of the importance therein of induction as compared with deduction. Comte devotes special attention to sociology and ethics; he finds the division of the forms of civilization into militaristic, juristic and industrial quite parallel to the threefold division of science. He desires to unite the treatment of the emotional and intellectual needs of man. For this purpose a new religion becomes necessary, the «Religion of Humanity,» and a new political Utopia. See POSITIVISM.

Classification of the Sciences' (New York 1864).

COMTE, Pierre Charles, French painter: b. Lyons, 23 April 1823; d. 1895. He studied at Paris as a pupil and adopted son of Robert Fleury, and exhibited his picture 'Lady Jane Grey,' in 1847, which won him considerable attention. His other works include 'Crowning of Ines de Castro' (1849); 'Henry III Meeting the Duke of Guise' (1855); 'Joan of Arc at the Coronation of Charles VII' (1861); 'A Scene at Fontainebleau' (at Washington, D. C.); 'Gipsies Before Louis XI'; 'The Last Visit of Charles V to the Castle of Ghent,' 'Winter' (1876); 'Don Quixote' (1877); 'Dante' (1878); 'Francis I at Fontainebleau' (1880).

COMTE DE PARIS, dẽ pä-rẽ. See PARIS, LOUIS PHILIPPE ALBERT D'ORLEANS, COMTE DE.

COMUS, kō'mŭs (Greek *kōmos*), in ancient Greece the name given to a kind of festal procession in honor of some of the gods (as Bacchus) and sometimes in honor of victors in the public games. The term had also the wider sense of revel and merry-making. This name was also given to a divinity supposed to preside over such festive occasions, but as his name does not occur in early ancient writers whose works have been preserved, he is evidently a creation of later times. He is first mentioned by Philostratus (about 200 A.D.).

COMUS. This is the title given to a masque by John Milton, produced in honor of the Earl of Bridgewater, upon his entrance on his duties as Lord President of Wales, at Ludlow Castle, on Michaelmas night, 29 Sept. 1634. The young Puritan poet was induced to furnish the words for the entertainment — such things were not in favor with most of his coreligionists — by a family friend, Henry Lawes the musician, who gave instruction to the Earl of Bridgewater's children. Three of these acted in the masque, and Lawes himself took the part of the Attendant Spirit besides furnishing the music. Apparently Milton about a year before had rendered Lawes a similar service by writing for him the less elaborate 'Arcades.' We know little about the production of 'Comus' or about its composition, save that it was written during what is called Milton's "Horton period," but it was evidently talked of admiringly, since in 1637 Lawes, to furnish friends with copies, printed an edition without the author's name, to which was prefixed a very complimentary letter by Sir Henry Wotton. In this edition, as well as in Milton's editions of his shorter poems in 1645 and 1673, the designation is not "Comus," but "A Mask." A manuscript copy in Milton's handwriting and another supposed to be in that of Lawes are extant. 'Comus' has naturally been subjected to much scholarly investigation, and numerous "sources" have been suggested — chiefly, the Circe myth as treated in the Odyssey and by poets drawing on that, notably Spenser; George Peele's play 'The Old Wives' Tale,' which gave Milton the kernel of his simple plot; Fletcher's 'The Faithful Shepherdess'; a play in Latin entitled 'Comus' by the Louvain professor Erycius Puteanus (Hendrik van der Putten); and Ben Jonson's masque 'Pleasure Reconciled to Virtue.' That Milton drew to some extent upon these and other works seems indisputable, but the fact does not impair his essential originality, which is seen, not merely in the unsurpassed charm, purity and philosophical elevation of his poem taken as a whole, but in his developing the shadowy Comus of mythology into a well-defined and not unimpressive character.

Criticism of 'Comus' has been in the main highly laudatory, not a few persons preferring it and the other poems of the "Horton period," 'L'Allegro' and 'Il Penseroso' and 'Lycidas,' to the works of Milton's later years, including even 'Paradise Lost.' On such a point argument seems useless. One who demands the sonorous sublimity of the great epic, the poised dignity of 'Paradise Regained,' the severe strength of 'Samson Agonistes,' will not find these qualities present in large measure in 'Comus.' On the other hand, one who delights in the fascinating style of 'Comus,' in the noble idealism of its portrayal of the power of virtue, in the pure lyrical and pictorial qualities of the closing portion beginning with the invocation to "Sabrina fair," is not likely precisely to renew his delights in the later poems. It is more catholic and profitable to enjoy the great poet both in this product of the graceful strength of his early genius and in the more powerful achievements of his riper years. We shall do this the more certainly if we avoid a tendency observable in some critics to deal with 'Comus' as though it were a regular drama. In its use of blank verse, its comparatively long speeches, its diminished insistence upon the more spectacular elements of the typical masque, 'Comus' does approximate a play, and thus Milton may be said to give some handle to those critics who demand from him a more realistic and convincing handling of his characters. One can, therefore, understand how some people regard the great speeches as fine poetry put into the mouths of uninteresting puppets, and how one biographer actually has the heart to call the elder brother a prig. But after all 'Comus' is not a play but a masque developed into a philosophical poem, and in this more or less unique capacity it should be judged. One may doubt whether the ideals of personal purity have ever been more inspiringly set forth than in this poem, in which exquisiteness and nobility seem to be perfectly blended. From such a point of view one does not need to realize the plight of the lost lady exposed to the wiles of the enchanter, or to enter into the feelings and watch the actions of the two brothers who seek to rescue her, with the intensity of conviction and sympathy that would be required if 'Comus' made the same demands as a regular drama. What one has to do is rather to give one's self up to the beauty of the style and the nobility of the thought, more or less leaving the action and the characterization to take care of themselves.

WILLIAM P. TRENT,
Late Professor Emeritus of English Literature, Columbia University.

COMYN, kŭm'ĭn, **John,** THE ELDER, Scottish noble: d. about 1300. He was one of the commissioners sent to confer about the marriage of the Maid of Norway to Prince Edward of England. On the competition for the Scottish throne in 1291 Comyn put in a claim as a descendant of Donald Bane.

COMYN, John, Scottish noble: d. Dumfries 1306. He was called the Red Comyn, was chosen one of the three guardians of Scotland and defeated the English at Roslin in 1302. He submitted to Edward I in 1304 and was killed by Bruce in the Convent of the Minorites at Dumfries in 1306, a well-known episode in the life of the great Scottish king. A sort of vendetta followed and many of the Comyns of succeeding generations perished in attempts to avenge the death of the Red Comyn.

CON, kŏn, an Italian preposition signifying with, and of frequent occurrence in musical phraseology; *con amore,* with feeling; *con brio,* brilliantly; *con gusto,* with taste.

CONANICUT, an island of Rhode Island, situated in the lower part of Narragansett Bay. It is about nine miles long and one mile wide. The town of Jamestown is near the east shore and there is a lighthouse at the north end. Pop. of township about 1,600.

CONANT, Alban Jasper, American artist: b. Chelsea, Vt., Sept. 24, 1821; d. New York, Feb. 3, 1915. He settled in St. Louis in 1857 and during the Civil War visited Washington and painted portraits of President Lincoln, Secretary Stanton and Attorney General Bates. He was a curator in the University of Missouri for eight years and made valuable studies of the archaeology and antiquities of the Mississippi Valley. In 1880, he was appointed Délégué Correspondant de l'Institution Ethnographique of Paris. He published *Footprints of Vanished Races in the Mississippi Valley* (1879, 4 to 1); *The Archæology of the Missouri Valley; My Acquaintance with Abraham Lincoln,* etc.

CONANT, Charles Arthur, American economic writer: b. Winchester, Mass., July 2, 1861; d. New York, July 5, 1915. He was for some years after 1880 a journalist in Boston, from 1889–1901 was Washington correspondent of the New York *Journal of Commerce* and, in 1903, became treasurer of the Morton Trust Company. He did important work for the gold standard and the gold-exchange standard and aided in the development of a monetary system in the Philippines. He was a member of the New York Chamber of Commerce committee on currency reform (1906), which recommended a central bank. In 1910, he was American delegate to The Hague Conference on Bills of Exchange. He wrote many articles for periodicals and encyclopaedias on American banking and on Latin-American finance and trade.

CONANT, Hannah O'Brien Chaplin, American author: b. Danvers, Mass., 1809; d. Brooklyn, N. Y., Feb. 18, 1865. In 1830, she married Thomas Jefferson Conant (q.v.). She was a woman of versatile talent, having an excellent knowledge of Oriental tongues, which enabled her to share in the biblical studies of her husband. She frequently contributed to the literary and religious periodicals of the day, and, in 1838, became editor of the *Mothers' Monthly Journal* at Utica, N. Y. She published many books of a religious nature.

CONANT, James Bryant, American chemist and educator: b. Dorchester, Mass., March 26, 1893. His entire academic life has been connected with Harvard University, where he received his B.A. degree in 1913 and his Ph.D. degree in 1916. He progressed from instructor in chemistry (1916) to professor of organic chemistry (1927), and on June 21, 1933, became the 23d president of Harvard University. During World War I, he served as a major in the Chemical Warfare Service of the United States Army. His scientific researches have been concerned with free radicals, superacid solutions, reaction rates, hemoglobin, and chlorophyll. In 1941, he was made chairman of the National Defense Research Committee, coordinating the original American effort on the atomic bomb project. When responsibility for this work was assumed by the War Department, he acted as scientific adviser to the Manhattan District and to other government agencies concerned with atomic energy.

CONANT, Thomas Jefferson, American biblical scholar: b. Brandon, Vt., Dec. 13, 1802; d. Brooklyn, N. Y., April 30, 1891. He was graduated from Middlebury College in 1823, and between 1825 and 1857 taught the classics and biblical literature in Columbia College, Waterville (now Colby) College, Maine, Madison, now Colgate University, Hamilton, N. Y., and Rochester Theological Seminary. Taking up the studies that soon gave him a wide reputation, he was appointed by the American Bible Union one of a committee to prepare a revision of the English version of the New Testament. He was also a member of the American committee on the English revision of the Old Testament, and his revisions were highly esteemed and constantly used by the English revisers. His numerous publications include translations of the 11th and 17th editions of Gesenius' *Hebrew Grammar; Job; Revised Version, and Notes* (1856); *Matthew, Revised Version* (1860); *The Meaning and Use of Baptizein* (1860); *Genesis, Revised Version* (1868; 1873); *The New Testament; Common Version Revised* (1871); *Psalms, Revised* (1871); *Proverbs, Revised* (1872); *Greek Text of the Apocalypse, as edited by Erasmus* (1873); *Prophecies of Isaiah, Chapters 1–12* (1874); and *Historical Books of the Old Testament, Joshua to 2 Kings* (1884).

CONATION (from Lat. *conari,* to attempt), a term in its original sense used simply to express the idea or to designate the act of attempting or undertaking something. In present usage it is appropriated by psychologists to the expression of desire and volition as manifested in or constituting voluntary agency, although as a factor in consciousness and effort its precise implications appear not to have been finally determined. In the exertion of the muscles, and in direct conscious attention, the agency of conation in an individual finds its two representative aspects. Attention, desire and endeavor, with their accompanying states of thought and feeling, are held by some psychologists to be the completing aspects of conation; while others maintain that its function is limited to the sensations of straining, with consequent states of consciousness, pleasurable or otherwise, attendant upon contraction of the muscles. Whether conation is to be regarded as simple or complex in its psychological aspects remains therefore a question for further research and experiment. Consult James, 'Principles of Psychology' (New York 1890); Titchener, 'Experimental Psychology'

(New York 1901); 'Text-book of Psychology' (ib. 1910); Hyslop, 'Syllabus of Psychology'; Stout, 'Analytic Psychology' (London 1896).

CONATY, Thomas James, American Roman Catholic prelate: b. Ireland, 1 Aug. 1847; d. Coronado Beach, Cal., 18 Sept. 1915. In 1850 he came with his parents to America, the family settling in Taunton, Mass., and in the district schools of that city he received his primary education. He entered the college of Saint Sulpice, Montreal, in 1863, completed his humanities in 1867, and spent the following two years at Holy Cross College, Worcester, Mass., being graduated in 1869. His ecclesiastical course was pursued at the Seminary of Saint Sulpice, Montreal, where he was ordained priest 21 Dec. 1872. First named assistant at Saint John's Church, Worcester, Mass., and afterward chosen pastor of the church of the Sacred Heart in that city, Father Conaty was actively interested in the advancement of Catholic education. He was likewise an ardent promoter of the temperance cause, being first president of the Springfield Diocesan Temperance Union, and, in 1887, national president of the Catholic Abstinence Union of America. Father Conaty was also prominent in establishing the Catholic Summer School in 1892 — the same now flourishing at Plattsburg, N. Y. — being its president from 1893 to 1897. In 1889 Georgetown University conferred upon him the title of D.D., and in 1896 Laval University, Quebec, bestowed the same honor. He was chosen rector of the Catholic University in 1896, made a domestic prelate in 1897, consecrated titular bishop of Samos, 24 Nov. 1901, and appointed bishop of Monterey and Los Angeles, 27 March 1903. He was a frequent contributor to various periodicals, and is the author of 'New Testament Studies' now used in many Catholic schools.

CONCENTRATION CAMP, sometimes applied to rendezvous near an intended point of departure of troops; but generally to a camp into which non-combatants are gathered in time of war. During the Cuban rebellion of 1895–98 many peaceable and defenseless people were forced to abandon their homes in the agricultural regions and were imprisoned upon the barren waste outside the residence portions of the cities, and within the lines of entrenchment. It is estimated that at least 400,000 persons, mostly old men, women and children, were thus subjected to concentration under Weyler's administration. They were known as reconcentrados. The British also carried on a scheme of concentration of non-combatants — men, women and children — during the Great Boer War, and in which provision was made for the education of Boer children. Provision was made at Mindanao, in the Philippines, in 1902, for the accommodation of non-combatants during the military measures undertaken by the American government. In 1914 about 5,000 Mexican revolutionists, driven across the border into American territory by government forces, were disarmed and interned temporarily in concentration camps.

CONCENTRIC, similar figures having a common centre are called concentric.

CONCENTRIC WEATHERING. See EXFOLIATION.

CONCEPCIÓN, Bolivia, a lake in the central portion of the department of Santa Cruz.

CONCEPCION, Chile, province lying between the provinces of Ñuble and Bio-bio. Area 4,334 square miles. Its area was increased in 1928 when the number of provinces was reduced. The importance of its capital, its commercial activity and its numerous ports make this the most interesting province in the south of Chile. Two of the largest bays in the republic are on its coast, those of Talcahuano, which is defended by fortifications, and Arauco, which includes the ports of Lota and Coronel, notable for their coal mines. The city of Concepción (64,074 inhabitants) is the capital. Talcahuano (22,084 inhabitants) is a military port, with a dry-dock for repairing warships and mercantile vessels, and at the same time an active commercial port. Products of the whole southern region are brought to it for exportation, and it supplies cities of the interior with a large part of their merchandise. The port of Tomé (5,000 inhabitants), situated near rich agricultural districts, exports a large quantity of wine and has a woolen mill, etc. Penco, a small port 10 miles by rail from the city of Concepción, is a favorite seaside resort and has a sugar refinery and coal mines in the neighborhood. The population of the province is 337,000.

CONCEPCION, Chile, the capital of the province of the same name. It is situated on the banks of the Bio-bio River, and is connected by a short railway with its ports of entry, Tomé and Talcahuano, eight miles distant on the Bay of Concepción. In the latter city a United States consular agent resides. The streets and squares of the city are wide, well paved, well lighted and clean. An electric railway traverses the principal streets. Concepción is the seat of a bishop. The chief buildings are the city hall, the cathedral, theatre, the agricultural school and the normal school. The city is in a fertile agricultural region and has an active trade in agricultural products, hides, tallow, wine, flour, beef, etc.; very little manufacturing is carried on, the largest establishment being breweries, furniture and carriage factories, saw-mills, flour-mills, distilleries, etc. It is in importance the third city of Chile. Concepción was founded in October 1550 by Pedro de Valdivia, and was originally situated on the site of the present city of Penco. In 1555 the place was pillaged and destroyed by Araucanian Indians; and in 1557 was refounded by Garcia Hurtado de Mendoza. In 1730 the town was totally ruined by an earthquake, and in 1751 suffered from a like catastrophe in consequence of which the site was removed and the city rebuilt in its present location in the fertile plain on the north side of the Bio-bio, 270 miles southwest of Santiago. At the time of the Spanish occupation Concepción was the second largest city in the country. In 1818 the declaration of Chilean independence took place here. In 1835 another disastrous earthquake visited the city and for a long time the place was almost entirely desolate, but it was afterward resettled and from that time the buildings have been more substantially and pretentiously erected, the streets reconstructed and the area of the city greatly extended. Pop. 64,074.

CONCEPCIÓN, Paraguay, also called Villa Concepción, the second city of the republic in commercial importance, though not in the number of its inhabitants. It is situated on the left bank of the Paraguay River, 125 miles from Asunción. It is a port of entry and delivery, where the steamers navigating the upper Paraguay regularly touch. The principal buildings are the city hall, custom-house, parish church, market and some fine private residences. It has a line of street-cars, telephone service, two banks, and several commercial houses that trade directly with Argentine and European cities. Yerba-maté or Paraguay tea and cattle are the principal items of the city's commerce. Pop. 15,000.

CONCEPCION, Philippines, former district of the island of Panay, now part of the province of Iloilo, situated on the northeast part of the island; area 683 square miles. The former capital, Concepción is a pueblo situated on the east coast of the island, 47 miles northeast of Iloilo; pop. 4,565. Pop. of the district about 20,000.

CONCEPCION, Philippines, town (pueblo) in Tarlac province in the island of Luzon, 12 miles south of the town of Tarlac. It has an important sugar industry; rice, tobacco and corn are also raised in the surrounding country. Pop. 12,593.

CONCEPCION DEL URUGUAY, Argentina, city in the province of Entre Rios, on the Uruguay River about 160 miles north of Buenos Aires. It is connected by railway with Paraná, and the river is navigable for large vessels, thus rendering the city an important shipping point. It is in an extensive and fertile agricultural region and the trade consists chiefly of these products and cattle and packed meat. There are also some salting establishments in the city. A national college and a normal school are located in the city. Concepción del Uruguay was founded in 1778 and was originally called Concepción-del-de-la-china; was formerly the capital of the province and is now the episcopal city. Pop. 25,000.

CONCEPT. A concept is an idea which has been formed by thinking, and which is permanently embodied in language by a word or other definite symbolic expression. There are two main differences between a concept and a percept. In the first place, the latter seems to be directly presented through the senses and does not imply any conscious reflection. And again, a percept as presented has always a particular individual form, while a concept is an ideal construction, and, as such, has universal significance. For example, I may perceive through my senses the particular object which I call my watch; but to form a concept of «watch» is to think in general terms the relation of the mechanism of the parts to the purpose of the whole. The concept must also be distinguished from the mental image which appears in memory or imagination when the object is not directly present in sensation. The latter is always a particular psychological process, and therefore cannot adequately represent the general relations of the concept. We must not confuse the presence of images in the mind with thinking. It is true that a concept cannot be represented in terms of psychological content except by a particular image, and it probably always is represented by some such image. But the concept is a universal mode of thinking, and the psychological imagery which accompanies it is largely individual and indifferent. The universal relations of the concept of triangle, for example, are not limited by the form of the particular figure which I represent to myself mentally, or draw upon paper, though the latter may aid me in comprehending those relations. The concept is ideal in character; it is a universal significance, and must never be confused with a particular psychological image.

Socrates was the first to bring this universal element of knowledge into clear light. When the Sophists pointed to the differences and variations of perceptions and feelings in individuals, and drew the conclusion that objective knowledge was impossible, Socrates showed that concepts which are true for all men can be discovered and defined, and that this is the true quest of thought. Amid the flux of individual opinion, science is still possible, since it is constituted by this system of universal concepts. Plato and Aristotle developed further the Socratic doctrine of concepts and gave it an ontological application. By means of the concept, the true form or permanent essence of things is said to be apprehended, as opposed to the accidental and changing appearances. The question as to the nature of the concept played an important part during the Middle Ages. (See NOMINALISM; REALISM; CONCEPTUALISM.) The view that is perhaps most commonly held to-day regards the concept as derived by abstraction (q.v.) from perceptual experience, by selecting out what is common in a number of instances and combining these common elements into a general idea. It must not be forgotten, however, that concepts are not formed by the piecing together of psychologically common elements in a mechanical way, but are the products of thinking; and that thinking is itself judgment or interpretation of significance in universal terms. It is true, as Kant said, that concepts without percepts are empty; our thinking does not go on in a vacuum apart from concrete experience. But the concept is not universal because it has been compounded out of elements that are common to a number of objects, but because it is the mind's expression in terms of ideal significance. Concepts, however, can attain to any degree of elaboration only through the aid of language. The relation between thought and the words which express it is of the closest and most intimate kind. The word sums up in itself the results of the conceptualizing process, thus giving to it a reality and permanence which make progress possible. It is through learning the words of a language that we are able to share in the concepts of other men and other generations. Language is thus a permanent record of thought's achievements, and its development is not something external to the evolution of thinking, but in one aspect may be said to be a different side of the same process. The concept then cannot be defined apart from its expression in language; for this expression is no mere external and accidental feature of the idea, but is organically and necessarily connected with it.

JAMES E. CREIGHTON,
Late Professor of Logic and Metaphysics, Cornell University.

CONCEPTION. This is a term signifying the beginning of the life of the child following fertilization, which latter is brought about by the union of the chromatic elements of the spermatozoon with the ovum. After orgasm (see COITUS), the male elements, or spermatozoa, many thousands of which are discharged in coitus, commence to move toward the mouth of the uterus, largely attracted by alkaline chemical substances which characterize the mucus membranes of the cervix and uterus. On entering the uterus they swim against a current there at a rate of about one eighth of an inch a minute. The entire length of the uterus can thus be traveled in about an hour or less. The ovum may be met in the uterus or in the Fallopian tube when fertilization takes place. The spermatozoan may live from five to eight days in the uterus or tube—the ovum a similar length of time—and impregnation may take place at any period between menstruations, although it is more likely when coitus precedes or follows within seven to eight days of the menstrual period. See also EMBRYOLOGY.

CONCEPTION, Immaculate, of the Blessed Virgin Mary. A dogma of the Roman Catholic Church, defined as such by Pope Pius IX in 1854. See IMMACULATE CONCEPTION.

CONCEPTION OF OUR LADY, Sisters of the, an order of nuns, founded in Portugal in 1484 by Beatrix de Sylva, in honor of the Immaculate Conception. It was confirmed in 1489 by Pope Innocent VIII, and the Cistercian rule was adopted. In 1489 Cardinal Ximenes put the nuns under the direction of the Franciscans, and imposed on them the rule of Saint Clara. The order subsequently spread into Italy, Belgium and France. The Sisters of the Immaculate Conception of the order of Franciscans were established at Little Falls, Minn., in 1891 by sisters from Italy. They now have several hospitals, an orphanage, an extensive school and nearly 100 teachers.

CONCEPTUALISM, kŏn-sĕp'tŭ-ăl-ĭzm, in metaphysics, a doctrine in a sense intermediate between realism and nominalism. Conceptualism assigns to universals an existence which may be called logical or psychological, that is, independent of single objects, but dependent upon the mind of the thinking subject, in which they exist as notions or conceptions. Thus, for instance, according to conceptualism, the meaning of a general class-name as horse, red, can be fully represented in thought or be actually present to the consciousness. Locke was the best known advocate of this psychological doctrine, which is little known outside of English-speaking countries. See also NOMINALISM; REALISM.

CONCEPTUALIST, one of a metaphysical sect—if indeed it has coherence enough to be called a sect—which arose in the Middle Ages during disputes between the nominalists and the realists; or one who holds the views of conceptualism. The conceptualist school sought to occupy an intermediate position, but is approximated much more nearly to the nominalists than to the realists.

CONCERT, a public performance of musical compositions without the aid of scenic representation. They were unknown before 1672 when the first concerts were established in London by John Banister. England continued the practice after Banister's death in 1679 and in 1725 the *concerts spirituels* were established in Paris. The organization of the latter was soon copied by organizations in France, Germany and England. The foundation of the Berliner Singakademie in 1790 inaugurated public performances of large choral works with orchestra. Consult Hanslick, E., *Geschichte des Konzertwesens in Wien* (Vienna 1869); Pohl, K. F., *Mozart und Haydn in London* (Vienna 1867); Schering, A., *Geschichte des instrumentalkonzerts bis auf die Gegenwart* (Leipzig 1905).

CONCERT PITCH, the pitch of a certain note in the musical scale adhered to by musicians generally. A commission of well-known composers, comprising Hector Berlioz, Giacomo Meyerbeer, Giacomo A. Rossini, and Ambroise Thomas, and several distinguished physicists, was appointed by the French government in 1858 to consider the subject, and in the following year they reported that the note A (above middle C) was produced by 435 vibrations. This standard gradually spread thereafter throughout most of Europe. In the United States, however, concert pitch for the note A is 440 vibrations. See also MUSICAL ELEMENTS AND TERMS; PITCH.

CONCERTINA, kŏn-sĕr-tē'nà, a musical instrument invented by Sir Charles Wheatstone in 1829. It is generally polygonal in shape, is held between the hands so that the fingers drop naturally down on studs which raise the valves and allow the air (supplied by the bellows between the finger-boards) to act upon a series of metal tongues of the same construction as those of the accordion or harmonium. The usual range of the instrument is from the lowest G on the violin to the C three and a half octaves higher, including the chromatic tones.

CONCERTO, kŏn-chĕr'tō. The concerto is frequently defined as a composition in sonata form (q.v.) for solo instrument, or instruments, with orchestral accompaniment; but as both orchestra and solo instrument, or instruments, now usually participate equally in most concertos, it would doubtless be more accurate to describe a concerto as a duet in sonata form for solo instrument, or instruments, and orchestra. Originally, the word concerto was used to denote an instrumental composition intended primarily to display the skill of a solo executant accompanied by an orchestra. James Gibbons Huneker once said ironically of this type of composition that Franz Liszt wrote cadenzas with orchestral accompaniment and called them concertos. Certainly since Liszt's time, concertos have been written with more purely musical purposes in view.

A double concerto is a composition in concerto form for two solo instruments and orchestra; while a *concerto grosso* is written for a group of solo instruments and orchestra. Of piano concertos, those of Beethoven, Brahms, Schumann, Grieg, and Tchaikovsky are perhaps the most popular, while other frequently played piano concertos have been written by Bach, Mozart, Liszt, Mendelssohn, Gershwin, Stravinsky, Prokofiev, and Shostakovich. Violin concertos of great popularity include those of Bach, Vivaldi, Mozart, Beethoven, Brahms, Sibelius, Bruch, Tchaikovsky, and Prokofiev. There are innumerable compositions for piano and orchestra not in

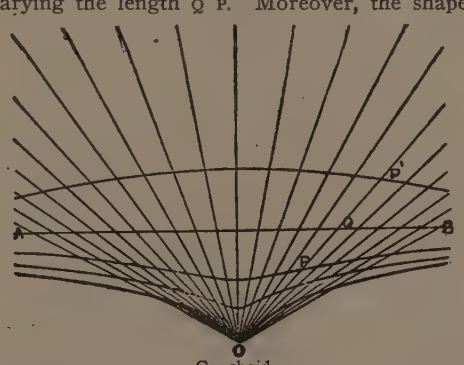
sonata form, and therefore not true concertos, which are frequently played, such as César Franck's Symphonic Variations. Similarly, there are compositions other than concertos for violin and orchestra which are frequently heard in the concert hall, as for example Chausson's *Poëme,* Chabrier's rhapsody *España,* and Lalo's *Symphonie Espagnole.* And there are innumerable concertos for practically all other solo instruments and orchestra, including especially concertos for flute, clarinet, cello, harp, harpsichord, viola, and oboe, with the orchestra.

CONCH, kŏnk (univalve mollusks), a name of certain large marine gastropods, especially of the king conch (*Strombus gigas*), abundant in the southern United States and parts of the West Indies. In Florida the shells are made into horns used for calling the farm hands, as is still done in the East Indies with shells of the genus *Triton.* Conch shells were in use over a large extent of territory in Mexico, Central and the northern part of South America for the manufacture of beads many centuries before the discovery of America by Columbus. This is one of the shells used for making cameos, and great quantities are collected in the Bahamas and shipped to Liverpool for this purpose to some extent, but more for conversion into buttons and similar small articles, in allusion to which industry the native whites of the Bahamas are called "Conchs." Conch shells are also used very extensively in the manufacture of lime and porcelain. The name is also applied to two large sea-snails, the *Fulgur carica* and *Sycotypus canaliculata,* common on most parts of the Atlantic coast.

CONCHA, José Gutierrez de la (Marques de la Habana), Spanish general: b. Cordova, Argentina, 4 June 1809; d. Madrid, Spain, 5 Nov. 1895. He went to Spain in childhood, entered the army, took part in the struggles in South America, and against Don Carlos, was appointed lieutenant-general in 1839, and officiated as captain-general of the Basque provinces 1843–46. He was captain-general of Cuba 1849–52, when he was replaced by Cañedo. Joining his brother Manuel (q.v.) in opposing the government, he was banished from Spain in 1854, and fled to France, where he was detained at Bordeaux. After the July revolution of 1854, he was reappointed captain-general of Cuba, and, with the exception of a short suspension of his functions by Narvaez's administration in 1856, when Lersundi was appointed as his successor, he continued to hold office until December 1858, when he tendered his resignation. Returning to Spain he was at various times Minister to France, president of the Senate and Minister of War, and captain-general of Cuba again 1874–75.

CONCHA, Manuel de la (Marques de Duero), Spanish general and statesman: b. Cordoba, Argentina, 25 April 1808; d. Muro, 28 June 1874. He was a brother of José Gutierrez de la Concha (q.v.), fought in early life against Napoleon and the revolted Spanish colonists in South America, and afterward against Don Carlos. In 1847, during the complications with Portugal, he was put in command of 6,000 men, and took possession of Oporto. Having issued at the end of 1853, in concert with O'Donnell and Bravo-Murillo, the famous protest against the policy pursued by the government, he was banished from Spain after the revolution of July 1854, and repaired to Paris; but was soon recalled to Madrid by the outbreak which terminated in the exile of Maria Christina, the downfall of Narvaez and the restoration of Espartero. Concha was now made inspector-general of cavalry, and marshal; but on 12 Oct. 1856, when Narvaez came again into power, he was compelled to relinquish these posts. He was killed in the battle of Muro while serving in the republican army against the Carlists.

CONCHOID, kŏng'koid, a curve, shell-like in flexure (whence the name), invented by Nicomedes in the 2d century B.C., and used by him for finding two mean proportionals. If a straight line always passes through a fixed point O, and a point Q, fixed into the revolving line, always moves along the line A B, then any point P in the revolving line always at the same distance from V will trace out a conchoid. And, since the length Q P can in any position of the revolving line be measured either toward or from O, it is evident that, corresponding to any given length assigned to Q P, two conchoids can be described, one above and the other below the line A B. These are known as superior and inferior conchoids. Moreover, with a given point O, and a given straight line A B, any number of pairs of different conchoids can be described by varying the length Q P. Moreover, the shapes



Conchoid

of all such curves will vary according to the length of Q P. Thus, if Q P is less than the perpendicular from O on A B, the shape is as given in the adjoining figure, and this isolated point O is also a point on the curve.

The equation of the conchoid is

$$x^2 = \frac{(b+y)^2\,(a^2-y^2)}{y^2}$$

when a denotes the length of the modulus and b the perpendicular distance from O to the line A B.

CONCHOLOGY, kŏn-kŏl'ō-jē, the science of shells. See Mollusca.

CONCHOS, kŏn'chōs, or **CONCHAS,** Mexico, river in the state of Chihuahua; rises high up in the Sierra Madre, flows southeast, northeast and then north through a beautiful country, comprising rich table-land, and empties into the Rio Grande near Presidio del Norte, after a course of about 350 miles. It is the largest tributary of the Rio Grande, and very little inferior in size to that river itself. Its principal branches are the Florido, Buenavista, San Pedro, Chihuahua and Balleza,

which, with their lesser tributaries, water more than one-third of the state.

CONCHYOLIN, kŏn-kī'ō-lĭn, an organic base allied to chitin (q.v.), which enters into the composition of the shells of mollusks. The conchyolin forms a thick cuticular layer of organic matter containing carbonate and a slight proportion of phosphate of lime. In dead shells the conchyolin soon disappears, leaving the shell much more brittle than when it was alive.

CONCIERGERIE, La, lä kôn-sē-ĕr-zhĕ-rē. A noted prison in Paris, which was a part of the Palais de Justice. Many royal prisoners were there confined, and during the Reign of Terror it was the scene of fearful butcheries, 328 prisoners being put to death in one week. Marie Antoinette went from her cell in this prison to her execution.

CONCILIUM IN TRULLO, or **CONCILIUM QUINISEXTUM** (Council in Trullus, Fifth-Sixth Council). A council or synod of the Church convened in a hall (called the Trullus) of the Imperial palace at Constantinople in the year 692. It was an assembly of Eastern and Western bishops called for the purpose of enacting canons of Church discipline; this the council did, adding to the existing canons 102 new ones and confirming ancient canons that had fallen into desuetude. Its work was to supplement the decrees of the 5th and 6th councils of the Church: hence it is known as the Quinisext Council.

CONCLAVE, the closed room or hall set aside for the cardinals when electing a Pope; also the assembly of the cardinals for the election. In the early ages the election of the successor of Saint Peter was most probably restricted to the clergy of Rome. After the 4th century the people were admitted, and the emperors were often represented. The clergy resented the influence of the emperors, and the clash of interest often resulted in long delays, sometimes in violent disputes. A decree of the Synod of the Lateran in 769 forbade the laity to have part in the election and in 1059 Pope Nicholas II placed power of election in the hands of the cardinals and conceded to the lower clergy and laity only the ceremony of assenting to the election. Finally the Lateran Council in 1139 placed the matter entirely in the hands of the cardinals, and for election required two-thirds majority of the cardinals present. When Clement IV died in 1268 the cardinals met for election at Viterbo. The election and consequent vacancy of the Holy See lasted two years and nine months. The local authorities lost patience in the end and shut the cardinals in a room with orders to elect a Pope at once. The action was effective and Gregory X was elected. Under him the second Council of Lyons decreed that thereafter the cardinals should assemble 10 days after the Pope's death, in the city where he died, and shut off from all outside influence proceed at once to the election. To prevent undue delay the decree ordered that if the cardinals came to no agreement within three days their food should be lessened and after a further delay of five days it was still more restricted. The decree of Gregory X is the beginning of the idea of conclave, and there we find the word first mentioned. The fundamental principle has lasted. Various changes were made from time to time till Pius X published his regulations in 1904. Pius XI completed the legislation by certain modifications during 1922. The constitution of Pius X (25 Dec. 1904) preserves the conclave idea of Gregory X. Before the conclave begins certain formalities must be observed. First the death of the Pontiff must be verified by the Cardinal Camerlingo, head of the papal household. He with three other cardinals arranges for the obsequies of the Pope and prepare for the conclave. Finally there is a "Congregatio" or meeting of the cardinals actually in Rome at which the laws governing the conclave are read, and the cardinals take oath to observe them. A commission is appointed to select and examine the officers of the conclave such as masters of ceremonies, confessors, physicians, servants of various kinds and the official marshal of the conclave. In the meantime the date is set for the opening of the conclave, and the place is appointed and made ready. In modern times the conclave is held in the Vatican palace. A large part of the palace is walled off and divided into apartments each with three or four rooms or cells. These are occupied by the cardinal with his secretary and servant. All are sworn to secrecy. Communication with the outside world is shut off. Cardinals may leave in case of illness, or enter if they arrive after the beginning of the conclave. Only cardinals have a right to vote. Even if the Pope should die during the progress of a general council the right of election is restricted to the cardinals. The law of Pius X clearly stated that the conclave should begin 10 days after the death of the Pope. However because of the inability of certain foreign cardinals to reach Rome within this time limit it was decided that 10 days were not sufficient. Hence by a decree dated 1 March 1922, Pope Pius XI decided that the conclave should not begin until 15 days after the death of the Pope. Election is by vote, which is taken by secret written ballot. Two-thirds are necessary for election. Ballots are usually taken twice a day till some one receives the number required. When the election is complete the other cardinals do reverence to the new Pope.

CONCORD, Mass., town in Middlesex County, alt. 135 feet, on the Concord River and on the Boston and Maine Railroad, 20 miles northwest of Boston; settled in 1635, the first inland town. The Massachusetts Reformatory is here. The Massachusetts Provincial Congress met here in 1774 and 1775 in the First Parish Church (now restored). General Gage sent a body of British soldiers to destroy arms and stores here (19 April 1775), but they were driven back to Boston. In Sleepy Hollow Cemetery are buried the «Concord authors»—Emerson, Thoreau, Hawthorne, and Alcott (father of Louisa May). D. C. French's statue of the Minute Man and his Melvin Memorial in the cemetery; the Antiquarian House, a museum; the Emerson House; the Old Manse, made famous by Hawthorne; the Orchard House where 'Little Women' was begun; and Grapevine Cottage, where Concord grapes were first raised (1840)—these are all tourists' shrines. Near by is Walden Pond, associated with the name of Thoreau. Municipal matters are decided upon at town meetings. Pop. (1940) 7,972.

CONCORD, N. C., city and Cabarrus County seat, alt. 704 feet, on the Southern Railroad, 21m. NE. of Charlotte. Once the center of a rich gold-mining region where gold was discovered in 1799, Concord is now a thriving cotton textile center. The city also manufactures foundry and machine-shop products and beer and soft drinks. Pop. (1940) 15,572.

CONCORD, N. H., city, Merrimack County seat, and capital of the state; alt. 288 feet; on the Merrimack River and the Boston and Maine Railroad; 73m. NW. of Boston. It has a municipal airport with airline service. Industries include granite works, textile mills, and factories producing a miscellany of products such as electric motors and instruments, stoves, sinks, wheels, organs, leather beltings, and novelties. There are city and state libraries in Concord; two general hospitals, a state hospital, and a state prison. The state house and other government buildings are in mid-city, enclosed by the business section. The state house, with the city and state library buildings, the National Guard armory, the building of the historical society, and the city hall, constitute an imposing civic center. The state house was built in 1819; an annex added in 1911. In front of it are statues of Franklin Pierce, Daniel Webster, Gen. John Stark, and U. S. Senator John P. Hale. (qq.v.). The New Hampshire Historical Society has preserved many interesting and valuable relics of New Hampshire's past: paintings (some by Samuel F. B. Morse), old pewter and glassware, tools, uniforms, and weapons. Mary Baker Eddy's birthplace, St. Paul's School, the famous granite quarries, and many fine old houses are points of interest near by. The city stands on land covered by a Massachusetts Bay Colony grant of 1659. The city's history begins with a re-grant of 1725, and settlement in 1727, by colonists from Haverhill, Mass. Originally called Penacook, it was incorporated as Rumford (town) in 1733, and reincorporated as the town of Concord in 1765. It became the state capital in 1808. It is governed by mayor and aldermen. The water supply system is municipally owned. Pop. (1930) 25,288; (1940) 27,171.

CONCORD, an expression used in music denoting the combination of two or more sounds pleasing to the ear, and requiring no further combination before or after it to make it so. Concords are the eighth (or octave), the fifth, third and sixth. Their ratios are 2:1, 3:2, 5:4, 5:3. The two first are called perfect, because as concords they are not liable to any alteration by sharps or flats. The two last are called imperfect, as being alterable. The fourth is considered as a discord by some authorities; as a component part of an inversion of the perfect chord it may be classed among the concords. See COUNTERPOINT.

CONCORD, Book of (*Liber Concordia*), the name given to a collection of confessions of faith which are generally accepted by the Lutheran Church. The Formula of Concord (1580) was the result of a series of conferences and discussions upon the following subjects: The Rule of Faith and the Creed; Original Sin; Free Will; Justification; Good Works; The Law and the Gospel; The Third Use of the Law; The Lord's Supper; The Person of Christ; The Descent of Christ into Hell; The Customs of the Church; Predestination and Election; Heresies and Sectaries. The whole received the sanction of a large number of the Germans. Other subjects treated in the Book of Concord are The Three Ecumenical Creeds—Apostles, Nicene and Athanasian; The Six Particular Confessions of the Lutheran Church — Augsburg, Apology of the Augsburg, Schmalkald Articles, Catechisms of Luther (larger and smaller). Consult Schaff, 'Creeds of Christendom' (Vols. I and III, New York 1878).

CONCORDANCE, a book in which the more important words of a volume or collection of writings are arranged alphabetically, part of a passage being extracted with each and the place of its use specifically given. The first known concordance of the Bible in any language was that of Saint Anthony of Padua, who was born in 1195, and died in 1231. His work was called 'Concordantiæ Morales,' and was of the Latin Vulgate. It formed the basis of a more elaborate concordance, also of the Vulgate, that of Hugo de Santo Caro, better known as Cardinal Hugo. This was published in 1244 A.D. The first Hebrew concordance was that of Rabbi Mordecai Nathan, begun in 1438 and finished in 1448. The first Greek concordance to the New Testament was that of Xystus Betuleius, whose real name was Birck; it came forth in 1546 A.D. The first English concordance to the New Testament was that of Thomas Gybson, before 1540 A.D.; the first to the whole English version of the Bible that of Marbeck, 1550 A.D. These, of course, preceded the appearance in 1611 A.D. of the authorized version of the Bible. The elaborate and well-known work of Cruden appeared first in 1737. All these works, with the exception of the last named, have been superseded by vastly improved works by modern scholars. Of the Septuagint the standard is that by Hatch and Redpath (London 1897); of the Vulgate, that by Coornaert (Bruges 1892), and that by Peultier, Etienne and Gantois (Paris 1902); of the Hebrew Bible the best is that by Furst and Delitzsch, in Latin (Leipzig 1841) and also that by Davidson, Tregelles and others, in English (London 1873); of the Greek New Testament are those of Bruder (Leipzig 1842; 5th ed., Göttingen 1900); in English Moultrie and Gedden (New York 1897); of Luther's Bible the best is that of Büchner (Jena 1740; 23d ed., Berlin 1899); of the English Bible in addition to Cruden are those by Young (Edinburgh 1879), Walker (Boston 1874) and Strong (New York 1894).

Scholars have also compiled concordances of the works of several great authors. The first known concordance to Shakespeare was that of Ayscough, in 1790. Mrs. Mary Cowden Clarke's elaborate and most useful work was first published in London in 1845, and in 1894 appeared a still more excellent one, that of John Bartlett, published in New York. A concordance to Milton was published in Madras in 1856 and 1857, and one to Tennyson in London in 1870 and another in 1912. Others of this kind are 'Dante's Works,' by E. A. Fay (Boston 1889); 'Omar Khayyam,' by J. R. Fultin (London 1899); 'Chaucer,' by the Chaucer Society (London 1872–); 'Pope,' by E. Abbott (ib. 1875); 'Cowper's Poetical Works,'

by J. Neve (ib. 1887); 'Gray,' by A. S. Cook (ib. 1909); 'Dickens,' by G. A. Pierce (ib. 1898); and by Williams (ib. 1907); 'Browning,' by Molineux (New York 1896).

CONCORDAT, kŏn-kôr'dăt (*concordatum,* or, plur., *concordata*), a compact or convention entered into by the Holy See and a secular government to determine their respective powers and rights in the regulation of ecclesiastical affairs within the jurisdiction of the state which is a party to the compact. The earliest example of such compacts is the convention between Calixtus II and the Emperor Henry V, concluded at Worms in 1122: it marked the end of the great dispute about investitures. In 1448 was concluded the so-called concordat with the German nation, or with the Emperor Frederic III, under which the patronage of ecclesiastical dignities in the empire was divided between the Imperial Crown and the Holy See.

A more comprehensive compact is that of which the foundation was laid at Constance in 1448, and subsequently modified by the Frankfort Concordat, and by that of Vienna, which last continued in use till the end of the Holy Roman Empire in 1803. Its place was supplied, under Pius VII and his successors, by separate concordats with Bavaria, 1817; Prussia, 1821; Baden, Würtemberg and several small states in 1818; Hanover, 1824; Saxony, 1827, and the Netherlands, 1827. A concordat was concluded at Vienna in 1855. Its chief provisions were that the Pope should have direct communication with the bishops, clergy and people; and archbishops and bishops with their priests and people, and the right to govern their sees according to the canon law. Education was put under the control of the Church. The bishops were to settle what books should be used. All questions of marriage, except so far as they involved civil consequences, were reserved exclusively to the ecclesiastical courts. The emperor had the power of choosing bishops, but with the advice of the existing bishops. The Church might acquire new property; but once acquired, it should not be sold or mortgaged without the consent of both Pope and Emperor. In 1868 this concordat was set aside in all the dominions of the Emperor of Austria.

In Italy, an agreement regulating the election of bishops was concluded with Nice and Savoy in 1451, and a formal concordat was made with Sardinia by Benedict XIV in 1740, and with Naples in 1741, and a new concordat was entered into with Naples by Pius VII in 1818. Charles V of Spain concluded a concordat with Adrian VI and Clement VII, and a further concordat was made by Clement XII and Philip V in 1737. A concordat with Portugal was made by Benedict XIV in 1741. Memorable is the concordat of 1515 between Leo X and Francis I; the King agreed to annul the pragmatic sanction of Charles VII, which restricted the right of appeal to Rome; and in return the Pope conceded to the king the right of nomination to all Church benefices within the realm, with a reservation of the *annates* to the Holy See, and with the proviso that the nominees should be acceptable to the Pope. Another celebrated concordat is that concluded 15 July 1801 between Pius VII and Napoleon as First Consul; it recognized the legal existence of the Catholic Church in France which had been annulled by the Revolution. The ecclesiastical topography of France was altered, the number of episcopal sees being reduced from more than 100 to 80. The confiscation of ecclesiastical property by the republican government was to pass for *fait accompli* and *res judicata* and the Pope and his successors were not to move to disturb purchasers or grantees of such properties. The government was to have the right of nomination of bishops, but the Pope that of canonical institution. Provision was to be made by the state for the support of bishops and clergy in lieu of their property, which had been appropriated by the Revolutionary government. This Concordat was abrogated finally in 1906. On 11 Feb. 1929, the Holy See concluded the Lateran Treaty and a Concordat with the Italian government, under which the sovereignty of the Pope over Vatican City was recognized.

CONCORDIA, or **CONCORD,** personified and worshipped as a goddess in Rome, where she had several temples, the most important of which was that in the Forum, erected by Camillus in 367 B.C. An annual feast was celebrated in her honor 16 January. She was represented with wreaths of flowers on her head, and in one hand a cornucopia, in the other an olive branch or a *patera.*

CONCORDIA, Argentina, town of the state of Entre Rios, on the Uruguay, 302 miles north of Buenos Aires by river. It has oil mills and slaughter-houses. It has a custom-house and a river trade exceeded only by that of Buenos Aires and Rosario, exporting salted meat, leather and Paraguay tea. It has railway connection with Paraná, Uruguay and South Brazil. Pop. 20,107.

CONCORDIA, Kans., city and Cloud County seat; alt. 1,362 feet; on the Republican River and on the Burlington; the Missouri Pacific; and the Union Pacific railroads; 137m. NW. of Emporia; has a municipal airport. It is the trading center of agricultural and stock-raising region. Concrete and mill products are manufactured. Concordia has good schools, a Carnegie public library, and active civic organizations. The North Central Kansas Music Festival is held each April at Concordia. The city has mayor and council; the water works are city-owned. Pop. (1930) 5,792; (1940) 6,255.

CONCORDIA COLLEGE, a co-educational institution under the auspices of the Lutheran Church, founded on 31 Oct. 1891 and located at Moorhead, Minn. In 1938 it reported a teaching staff of 41 members, 513 students; grounds, buildings, etc., valued at $690,158 and an income for the year of approximately $131,760.

CONCRETE (from Latin *concretus,* "that which is grown together"), an artificial stone, a composition of hydraulic cement, sand and broken stone, used for a long time for submarine foundations, and since 1890 more and more in place of building stone. In place of hydraulic cement pure lime was originally used and the name concrete applied only to this compound, "beton" being the proper term for the composition based on hydraulic cement until it became the only method. The mixture of sand

and cement is termed the matrix, and the broken stone or other addition is styled aggregate and is composed usually of local crushed stone, but may be slag, coke, broken bricks, gravel or pebbles. The ideal aggregate is broken, sharply angular and irregular stone, as this material mixes better with the matrix than rounded pebbles, minute particles of gravel or the more spongy brick shell or coke, although broken stone or gravel may be used advantageously in connection with pebbles, even in such small proportion as three to five. Broken limestone is considered especially efficacious as an aggregate, possibly because of an affinity between the molecules of carbonate of lime in it and the matrix. The proportions of the various parts approximate 1 part of cement, 3 parts of sand and 4 to 6 parts of aggregate, but no fixed norm is to be followed, the true rule being that the cement paste is to be thoroughly incorporated with sand coating each particle and that the matrix thus formed shall fill all interstices in the aggregate. In the process of mixture there are two extreme methods of watering, one very wet and the other scarcely more than moist. The spraying is followed by a mixture by shovel or by mixing machines. These machines are of two types: continuous, a trough or cylinder with a revolving screw shaft which works until the mixture is complete; and intermittent, a box being rotated slowly. The concrete may either be made into blocks, one layer of comparatively small depth being made at a time. By the newer method it is applied to its place on the building or foundation in the soft state and allowed to harden there. The world is indebted to Germany for the revivification of the concrete industry. They diffused a wider knowledge of the artificial manufacture of cement from lime and clay (see PORTLAND CEMENT), and demonstrated that the degree of expansion and contraction of structural steel and concrete under changes of temperature were the same. The United States was very prompt to make use of this development, which has so greatly altered building construction throughout the civilized world. While the large use of concrete is a comparatively modern development, it was employed in ancient times and in some of the most renowned works of history. The factitious stones employed by the Babylonians and the early Egyptians, as well as among the Greeks and Romans and at the present day in Barbary and among the nations of Malabar, were all a species of beton. Pliny mentions that the columns which adorn the peristyle of the Egyptian labyrinth were of this material, and the great length of time it has existed (over 3,600 years) shows the durability of this mode of construction. Puzzuolana, a volcanic earth, formed the basis for an excellent natural hydraulic cement used by the Romans. The aggregate consists of broken stone and was poured in wooden molds. In Rome the pyramid of Ninus is formed of a single block, as was also the square stone that formed the tomb of Porsena, which was 30 feet wide by 5 feet high. The Romans made free use of this material in constructing their walls, aqueducts, piers and roads, many portions of which exist at the present day. The mole which shelters the harbor of Algiers is so much exposed to the effect of winds that breaches were continually being made in it by the force of the sea, and to such an extent that in former times the Moors were compelled to employ a large number of workmen constantly repairing it, at an annual expenditure of over $60,000. Between 1833 and 1840 the French rebuilt this with concrete, or beton as it was then called, this being among the earliest of modern successful use of artificial cement-made stone. The action of the sea is so tempestuous here that the engineers calculated that stone blocks would have to be of about 350 cubic feet to remain in place. The impracticability of quarrying and transporting such enormous blocks of stone led to the employment of artificial stone or beton. Two kinds of blocks were manufactured: the first in the water, in the place they were intended to occupy, and the second on shore, to be afterward thrown into the sea. In the process of reconstruction, these blocks were used as follows: Those of the first kind, made in lined caissons, formed an outer sea line; on these blocks molds were placed filled with beton, and after these second blocks had set, they were launched into the sea, forming a line in front of the first; the intervening space was then filled up with blocks of natural stone. Behind this embankment thus formed, the ground was dredged to a depth of over six feet, and the whole of this space filled up with a continuous mass of beton. The entire work was performed in five years, at a cost of less than $420,000, notwithstanding that the mole, at the time of the occupation of Algiers by the French army in 1830, was in a state of complete dilapidation, in spite of the extensive repairs which had been annually executed upon it by the Moors during a period of two centuries. Marine works of the above character present numerous advantages over constructions in which natural stone is employed, of which the following are some of the most prominent: (1) immediate stability, while ordinary *pierre perdue* is never secure; (2) incomparably greater facility in transportation, which is always expensive and troublesome when blocks of stone are to be quarried exceeding 100 cubic feet; (3) a considerable reduction in the sectional area of the pier, and consequent economy of cost; and (4) that the system can be applied in every locality, now that our advanced knowledge of the subject of hydraulic mortars enables us to manufacture beton in any place where it may be needed. See BRIDGE; CONCRETE CONSTRUCTION.

CONCRETE CONSTRUCTION.—Concrete is a compound of gravel, broken rock or other aggregate, bound together by means of hydraulic cement, coal tar, asphaltum, or other cementing materials. Generally when a qualifying term is not used, portland cement (q.v.) is understood. (Definition adopted by the American Concrete Institute in 1923.)

Generally the aggregates are separated into coarse (diameter of particles more than ¼ inch) and fine (diameter of particles less than ¼ inch) aggregates. If fine aggregates only are used, the material is termed *mortar*.

Ordinary or plain concrete is a brittle material, not suitable to resist tension. It is used in massive members (masonry structures) subject primarily to compression. Concrete into which steel bars are placed to supply strength at places where the strength of the concrete alone would not be sufficient to perform the function

required of it is termed *reinforced concrete.* In reinforced concrete members, the reinforcing steel and concrete act as a unit, complementing each other in strength while the concrete protects the steel from fire and corrosion. Only structural members where both materials participate in resisting loads should be properly termed reinforced concrete.

Typical examples of plain (not reinforced) concrete structures are gravity dams and gravity retaining walls. Columns, slabs, and girders can be built of reinforced concrete, while tie beams and steel columns encased in concrete for fire protection, although utilizing both steel and concrete, cannot be considered in the sense of the above definition as reinforced concrete members.

History.—Concrete construction was known to the Romans; cement used at that time was a material known today as puzzolan (pozzolana) cement. Only since the invention of portland cement, first patented in 1824 by Joseph Aspdin of Leeds, England, did concrete as a basic material of construction gain great importance. The name "portland cement" was used because of the similarity which the hardened cement has to the stone found on the Isle of Portland. The term "concrete" dates back to the first quarter of the 19th century. Natural cements were made and used as far back as 1756 in England and 1818 in the United States. Large-scale manufacture of portland cement began with the invention of the rotary kiln in 1892.

The direct forerunners of reinforced concrete construction were masonry walls and arches reinforced with iron bars and ties to prevent cracking and opening of the joints. Joseph Monier, the French gardener, is usually named as the inventor of reinforced concrete. In the year 1861 he used metal pieces for the reinforcement of concrete pots and shortly afterward patented this method as the "Monier Construction." However, as early as the year 1850 the first reinforced concrete boat was built by the Frenchman, Joseph Louis Lambot and four years later a reinforced slab construction was patented in England by W. B. Wilkinson. In 1861 the principles of reinforced concrete systems were described and published by François Coignet, which although in a crude form, agree with modern notions on this material. Systematic scientific investigations were carried on by the son of Coignet, by François Hennebique in France, and by G. A. Wayss and Johann Bauschinger in Germany (1877). Similar investigations were undertaken by the American pioneers W. E. Ward, who built his first reinforced concrete house in 1872 and by Thaddeus Hyatt who published in 1872 the results of his experiments on beams, slabs, data on fireproofness, modulus of elasticity and strength of this new material. The Austrian engineer, Joseph Melan, published methods for the design of large span reinforced concrete arches. By the end of the 19th century the theory of reinforced concrete was well developed; theoretical investigations and practical solutions existed for highly complex structures, and for all traditional elements such as columns, beams, girders, arches, frames, and slabs. All these elements corresponded to similar elements found in other construction systems employing lumber, steel, and masonry. However, reinforced concrete construction had some inherent properties, not characteristic of traditional methods, which had to be further exploited and developed.

The first step toward this was the introduction of the flat slab construction by the American, C. A. P. Turner in 1906 and by the Swiss engineer Robert Maillart in 1908. The flat slab system takes full advantage of all properties of the concrete slab rigidly connected to columns, dispensing with the use of separate girders, and making the slab itself the main carrying element of the structure. The advanced methods of analysis introduced at the beginning of the 20th century allowed full utilization of the continuity of reinforced concrete column and girder combinations. A further step in the active utilization of thin slabs was the introduction of the various shell type constructions. Taking full advantage of the continuity and the ease with which the dimensions and shapes can be adapted to satisfy specific conditions and functions permitted by the use of reinforced concrete, an entirely new type of construction has been developed which bears but little similarity to other systems.

At the end of the 19th and the beginning of the 20th century a number of disastrous failures of reinforced concrete structures instigated the improvement of design methods. Further development was spurred by the improved technique of mixing, controlling, and placing of concrete.

Reinforced concrete construction developed all over the world into an important part of the building industry. In Europe, especially in countries poor in iron, this construction method provided means of great savings in steel, and therefore became popular sooner than in the United States, where after a forceful beginning, great resistance was encountered against its general acceptance, but during World War II the scarcity of steel gave impulse to the general acceptance of reinforced concrete.

Ingredients of Concrete.—When the ingredients of concrete are mixed with cement the addition of water forms a paste. This paste surrounds the particles of the aggregates and binds them together to form concrete. Only through the use of proper types of ingredients mixed in the necessary proportions can suitable concrete be obtained. Through the control of ingredients the quality of the obtained concrete can be controlled and adapted to various types of uses. Ordinary concrete consists of the following ingredients: portland cement, fine aggregate, coarse aggregate, water, and sometimes special admixtures. Each of these materials must conform to rigid specifications.

Portland Cement.—This is the actual binding agent of the ordinary concrete. Cement and water form a paste in which chemical reactions take place and cause the paste to harden. The most important compounds in portland cement with regard to its strength are: tricalcium silicate (C_3S) and dicalcium silicate (C_2S). These two make up usually 72 per cent of all other compounds found in portland cement. The rest of the compounds present are mostly less essential and desirable but unavoidable materials. Variation of the compounds results in various types of portland cement as: high early strength, standard, modified, sulphate-resisting and low-heat types. Besides portland cement, some other types, especially aluminia cements (also called

bauxite cements) are used especially in France and central Europe.

Cement is a finely pulverized material and should be kept dry at all times prior to use. It is usually shipped in the United States in bags of standard weight of 94 pounds; it is usually measured in barrels equivalent to four bags. In countries where metric units are adopted, the standard weight of a bag is 50 kilograms.

Aggregates.—Aggregates serve as filler in the concrete, reducing the amount of cement paste required for a given volume of concrete, thereby reducing its cost. Aggregates make concrete durable and decrease the change of its volume due to variation of the moisture content. The aggregate constitutes the bulk of the concrete (around 80 per cent of the volume in standard mixes). Therefore proper attention has to be given to its chemical and physical characteristics. Standard aggregates consist usually of natural sands and gravel, crushed rocks or mixtures of these materials. Artificial aggregates consist usually of crushed, air-cooled blast furnace slags and specially burned clays. Lightweight aggregates are used to reduce the weight of the concrete. They are manufactured by vitrifying and expanding clays, shales, cinders, and like materials, or are natural materials like crushed minerals, lava, and tufa.

Aggregates are required to be clean (free of dirt, deposits like mica, clay, coal and other organic matter, chemical salts, surface coating), hard, strong, and durable. The shape of the aggregate particles should be rounded. The presence of excessive quantities of flat, elongated, and sharp angular fragments is objectionable, although the latter are admitted in aggregates obtained from crushed rock. The specific gravity of aggregates is a fairly reliable index of its soundness and strength. The permissible lower limit of the specific gravity of aggregates is usually set at 2.50.

To obtain economic and dense concrete various sizes of aggregates are required. The separation of different sized particles is called grading, which is usually obtained by passing the aggregate through different sized screens or sieves. Fine aggregate includes all particles from very fine (exclusive of dust) up to those which will just pass through a screen having meshes ¼ inch square. Coarse aggregate includes all particles above the size of fine aggregates. The maximum dimension of the aggregate depends on where the concrete is employed. In thin slabs and walls it is recommended that the largest piece of aggregate should not exceed ⅓ (or even ⅕) of the thickness of the member in which it is used, nor ¾ of the clear spacing between reinforcing bars. In thick foundation walls and footings, aggregates ranging to 1½ inches and above are used; in solid masonry structures, like gravity dams, whole rocks are sometimes included.

Water.—In general, water that is fit to drink is suitable for mixing with cement. It especially has to be free from alkali, oil, and acids.

Admixtures.—Admixtures are usually powdery siliceous or clayey products or hydrated limes and are employed mainly for the purpose of improving workability of the concrete and should not be considered as replacement for cement. Calcium chloride is sometimes employed for the purpose of increasing early strength, as an admixture, in amounts up to 2 per cent of the cement by weight.

Reinforcement.—Besides the above listed ingredients, reinforced concrete contains a varying amount of reinforcing steel in the form of bars, rolled structural sections, or wire mesh. Reinforcing bars are usually of round or square cross section, ranging from ¼ inch to 1¼ inches in diameter. In Europe, plain bars are commonly used, while in American practice the deformed bars are preferred, that is, bars which are rolled with small projections to engage the embedding concrete. The bars or reinforcing wire mesh are usually graded according to the steel used, such as structural, intermediate, and hard grade. Besides ordinary plain and deformed bars, a number of other patented bar shapes are available.

The use of steel as reinforcing in concrete members is made possible by the facts that: (1) concrete adheres or bonds to steel in a great degree, which insures a complete participation of both materials in transmitting stresses induced by exterior forces; and (2) the temperature expansion coefficient of steel and concrete is very nearly equal, and therefore steel and concrete contract or expand the same amount.

Proportioning of Ingredients—Design of Concrete Mixes.—As mentioned previously, the proportioning of the ingredients has a very great influence on the concrete. Its basic qualities, like strength, workability, permeability, durability, fire resistance, volume change, and specific weight depend on the type and proportions of ingredients used. This fact was recognized early in its development, but not fully understood and utilized until about 1930. Fundamental discoveries and developments have made the proportioning of ingredients an exact engineering procedure, in contrast to earlier haphazard methods. The procedure of determining the proportions and types of ingredients is therefore referred to as "the design of concrete mixes." The ultimate aim of this process is to obtain a "good uniform concrete." The *uniformity* of a given type of concrete mix is the basic factor, which allows the assumption that every batch of a mix will result in concrete of the same uniform quality. This uniformity is obtained and ascertained by proper control, mixing, handling, and continuous tests. The good qualities of concrete can be classified basically as *strength, durability, and economy.* These qualities, besides being influenced by the same factors as the uniformity, depend on the design of the mixture, and the treatment of the concrete after having been placed, which is referred to as curing. The design of the mixture can also influence to some extent the uniformity, as for instance, certain aggregate types and proportions tend to give uneven concrete. The meaning of strength is self-explanatory. Durability of concrete is determined by its resistance to weathering (temperature variations, moisture variations, freezing and thawing), to chemical attack (leaching, chemical corrosion), resistance to wear (running water, mechanical abrasion). Economy, besides its obvious implications, includes workability of the mix. It should be easily handled during placing; that is, the concrete has to flow easily into the sometimes complex shapes of the formwork, filling out completely and uniformly all corners and also the space between reinforcements. Workability, be-

sides having its economic implications, has great influence on the final quality of the whole structure and therefore it is often treated as an independent requirement, not included under the heading "economy."

Before the modern theories of proportioning of ingredients were established, a number of methods were generally in use. All these methods had the aims stated above which were attained in varying degrees. Although with the use of these earlier methods a very great number of important constructions were built, they do not satisfy the present day requirements of economy, safety, and efficiency of engineering design. Therefore, the description of these methods is only of historical importance, although some dated procedures are still being used, without valid justification.

One of the most popular methods was the one using arbitrary proportions. This was based on the principle that the volume of voids in the coarse aggregate makes about 50 per cent of its total volume (measured by loose volume). In order to obtain a dense concrete, all these voids are filled out with a corresponding amount of fine aggregate. This leads to a ratio of 1 to 2 between the volumes of the fine (sand) and coarse (gravel) aggregate. The amount of the cement is determined by judging the quantity necessary to obtain the desired strength. The amount of water is determined mainly by its influence on the workability of the mixture. This method resulted in the familiar concrete proportions like 1:2:4, giving the proportions of the volumes of cement, sand, and gravel. Further refinements of this method led to specifying the minimum amount of cement required per unit volume of finished concrete and to determining with more exactitude the volume of the voids and specifying that the fine aggregate has to fill out completely the voids between the coarse aggregate, while all remaining voids shall be filled out by the cement paste.

Other methods aimed at the determination of the proper grading of the aggregate. They led to the development of the grading of aggregates by various techniques of mechanical analysis, establishing standard sieves for the grading. Also trial mixes were used to determine the combinations of aggregates of a given volume which would produce the heaviest and therefore the densest concrete. The principles on which most of these methods were based are still valid. Modern theories apply them with precise methods of procedure.

The cornerstone of the modern theory is the fact that using the same type and amount of cement and aggregates, *the mix which has the highest concentration of cement in the cement paste, will have the greatest strength.* This theory was first stated and proved by the American, Duff A. Abrams in 1918 and probably is one of the most important contributions to the development of concrete construction techniques. The measure of the concentration of cement in the cement paste is the ratio of the mixing water to the amount of cement used in the paste. It is usually expressed in the United States in U. S. gallons of water per sack of cement, commonly referred to as the water-cement ratio. The surface water or moisture carried by the aggregates has to be included as part of the mixing water. Designing of the concrete mixture can be reduced to (1) selection of the water-cement ratio which will produce the required strength and durability; and (2) selection of the combination and types of aggregates which will give the desired workability and economy.

The influence of the water-cement ratio on the strength of the concrete can be formulated in a variety of types of equations and can be represented in its simplest form as: $f'_c = M + N(c/w)$, where f'_c is the compressive strength of the concrete, M and N are empirically determined constants and c and w are relative weights of cement and water. The above formula leads to the so-called simplified design method of concrete mixes, whereby to any selected water-cement ratio a certain compressive strength at the 28th day after placing the concrete can be assumed. The following table gives the assumed compressive strength of concrete in pounds per square inches at 28 days for various generally employed water-cement ratios in U. S. gallons per 94 pounds sack of cement:

Water-cement ratio	Assumed compressive strength
7.50	2,000
6.75	2,500
6.00	3,000
5.00	3,750

Another method of determining the proper water-cement ratio, which is more precise, is based on tests made with various trial mixes. This method relies on the fact that the workability of a mix, by maintaining the same type and graduation of aggregates and amount of water, does not change considerably by varying the amount of cement.

The water-cement ratio also has great influence on the durability of the concrete. The following table gives recommended water-cement ratios for different types of structures and various degrees of exposure. The data are valid only if the concrete is cured; that is, it is protected from loss of moisture for at least seven days after having been placed.

The classification of various degrees of exposures means the following conditions: *Ex-*

Exposure	Class of structures		
	Reinforced piles, thin walls, light structural members, exterior columns and beams in buildings	Reinforced reservoirs, water tanks, pressure pipes, sewers, canal linings, dams of thin sections	Heavy walls, piers, foundations, dams of heavy sections
Extreme	5½	5½	6
Severe	6	6	6¾
Moderate	6¾	6	7½
Protected	7½	6	8¼

treme: in severe climates, as in northern United States, exposure to alternate wetting and drying, freezing and thawing, as at the water line in hydraulic structures; exposure to sea and strong sulphate waters in both severe and moderate climates. *Severe:* in severe climates as in the northern United States, exposure to rain and snow, and freezing and thawing, but not continuously in contact with water; in moderate climates as in southern United States, exposure to alternate wetting and drying, as at water line of hydraulic structures. *Moderate:* in climates like southern United States, exposure to ordinary weather, but not continuously in contact with water; concrete completely submerged, but protected from freezing. *Protected:* ordinary enclosed structural members, concrete below the ground and not subject to action of corrosive ground waters or freezing and thawing.

The workability and economy of concrete are determined by the types and grading of aggregates. Usually the workability alone is a good measure of the efficiency with which the concrete can be placed. This, in connection with the amount of cement used, will determine the cost of the concrete. The workability of the concrete depends on the consistency of the mix, which can range from fluid to stiff plastic mixtures. The usual field measure of the consistency is the amount of slump measured in inches, of a 12-inch high truncated cone-shaped concrete mixture, after the enclosing metal form is lifted.

The following table gives recommended slump values in inches:

Type of structure	Minimum slump	Maximum slump
Massive sections, pavement and floors laid on ground	1	4
Heavy slabs, beams, or walls	3	6
Thin walls and columns, ordinary slabs or beams	4	8
Mortar for floor finish		2

To obtain a desired consistency the procedure is this: First, a cement paste is made in the water-cement ratio which will give the required strength. Then the aggregates are added to the paste in the amount and proportion which with the paste will produce the required slump. *The total amount of aggregates* used with a given paste will determine the consistency of the mix. A stiffer mix uses more aggregates and therefore is economical in material requirements. Stiff, dry mixes, on the other hand, increase the cost of handling and placing, while the placing of well-lubricated fluid mixes is relatively less costly. Excessively wet mixes are also difficult to place, because such mixes have the tendency to be segregated during pouring into the original ingredients of paste and aggregate, thus producing an uneven concrete. Increasing *the relative amount of coarse aggregate* up to a certain limit reduces the amount of cement per cubic yard of concrete. Above this limit the saving in cement is very slight, while the deficiency in the mortar again decreases the workability, for the lack of the lubrication. On the other hand, increasing the proportion of fine materials (that is, fine aggregate and cement) results in smoother mixes, which can be easily placed. Excessive amount of mortar requires greater proportions of cement and therefore it is again uneconomical. The following table gives the recommended proportions of aggregates, which should be used with the various sizes of coarse aggregates:

Maximum size of coarse aggregate in inches	Ratio of fine to total aggregate on basis of dry compact volumes, measured separately	
	Minimum	Maximum
⅜	0.55	0.70
¾	0.40	0.60
1 and over	0.30	0.50

The finer the sand, the lower will be the percentage required.

All aggregates used ordinarily in concrete contain some moisture. This moisture has to be counted as part of the mixing water, and therefore should be determined to make the proper correction in the actual quantity of water added to the mixture to obtain the desired water-cement ratio. In correction for moisture only the free or surface water has to be considered. If dry aggregate is used, allowance may be made for the absorption for a certain amount of water during mixing and handling.

Approximate quantity of surface water carried by average aggregates

	Gallons per cubic foot
Very wet sand	¾ to 1
Moderately wet sand	½
Moist sand	¼
Moist gravel	¼

Absorption of aggregates in per cents by weight

Average sand	1.0
Pebbles and crushed limestone	1.0
Tap rock and granite	0.5
Porous sandstone	7.0
Very light and porous aggregate as high as	25.0

Weights and Quantities of Materials.—The apparent specific gravity of cement is 3.1; of the common aggregates 2.65. The absolute volume of a loose material is the actual total volume of solid matter in all the particles. The unit weight is the weight of the material per unit volume. Unit weight cement is 94 pounds per cubic foot, of aggregates about 100 pounds per cubic foot, depending on dimensions and moisture content. With this data, if the amounts of ingredients in a given mix are known, the total volume of concrete can be determined by adding the absolute volumes of all ingredients.

The total volume of concrete produced from certain amounts of ingredients is a measure of the economy of the mix. The absolute volume of the ingredients can be calculated from the following formula: $V = w/G \times 62.5$, where V = absolute volume, w = unit weight, G = apparent specific gravity. The coefficient 62.5 is the unit weight of water in pounds per cubic foot. This formula will give the absolute volume in cubic feet if the unit weight of the aggregates is given in pounds per cubic foot, measured in surface dry state. The following example will give an illustration for the computations which are made to determine the concrete produced from a given trial mixture: The batch consists of one bag of cement (94 pounds), 2.2 cubic feet of dry fine aggregate, having a unit weight of 110 pounds per cubic foot and 3.6 cubic feet

of dry coarse aggregate with a unit weight of 100 pounds per cubic foot. The water-cement ratio is 7 gallons per sack.

Cement: 1 cubic foot:

$$1 \times \frac{94}{3.1 \times 62.5} = 0.49 \text{ cubic foot absolute volume}$$

Fine aggregate: 2.2 cubic feet:

$$2.2 \times \frac{110}{2.65 \times 62.5} = 1.46 \text{ " feet " "}$$

Coarse aggregate: 3.6 cubic feet:

$$3.6 \times \frac{100}{2.65 \times 62.5} = 2.18 \text{ " feet " "}$$

Water: $\frac{7.00}{7.50} = 0.93$ " foot " "

Total volume of concrete produced = 5.06 cubic feet

The yield of above ingredients, that is the amount required to produce one cubic yard of concrete, can be calculated from the above values and gives 1.33 barrels of cement, 0.43 cubic yard of fine and 0.71 cubic yard of coarse aggregates per cubic yard of concrete. These values neglect absorption or losses during manipulation.

Fabrication of Concrete.—Once the selection of ingredients and the design of the mix is accomplished, the following processes are required before the fabrication of concrete is accomplished: (1) control tests for suitability of materials and uniformity of concrete; (2) measurement of materials; (3) mixing; (4) transportation; (5) placing and finishing; (6) curing as regards moisture and temperature; (7) follow-up tests of concrete to confirm quality.

Control Tests.—Before and during concreting operations, it is necessary to make sure that the materials used are generally suitable and conform to specifications established during the design of the mix. Most of these tests are made in accordance with some established and adopted testing procedure. In the United States, test procedures established by the American Society of Testing Materials (ASTM) are most frequently used and adopted.

Cement.—A number of tests have been established by the ASTM to insure dependable and satisfactory concrete. These testing procedures are adopted as a standard by the United States government and enforced by the manufacturers of cement; therefore, no other tests on cement are usually required.

The aggregates are usually tested for a number of qualities, but it is important that the test samples shall be really representative of the bulk of the materials used. Standard methods of sampling are established for this purpose. (ASTM designation: D75-39T). The most important tests to which aggregates should be submitted are the following: (1) test for organic impurities (ASTM C40-33); (2) test for objectionable fine material (ASTM C117-37); (3) test for grading (ASTM C136-39); (4) test for moisture and bulking (ASTM C29-39); (5) test for consistency (ASTM C143-39). This latter test consists of measuring of the slump, as described previously.

Measurement of Materials.—The accurate measurement of the ingredients is necessary to produce economic and uniform concrete. Volumetric measurements have been used in the past, but modern requirements connected with the accurate design and control of mix have produced weighing devices which are now used extensively. The weighing devices eliminate the bulking corrections but adjustment for the moisture content of aggregates must be made. The cement is usually measured in sacks of standard weight and it is convenient to determine the quantity of the other ingredients in relation to multiples of one sack of cement. The correct measurement of the quantity of mixing water is especially important. The water is measured by weight or volume and many concrete mixers are equipped with water-measuring devices.

Mixing.—In order to produce uniform concrete, all ingredients have to be thoroughly mixed. The hand mixing of the past has been replaced almost exclusively with machine mixing. Mixing machines have been brought to high efficiency producing concrete at minimum cost of labor and power, and eliminating loss of materials. The drier and harsher the mix, the longer will be the necessary mixing time. Tests show that the strength of the concrete increases with the period of mixing time. One minute of mixing is usually sufficient; sometimes two minutes are specified. From the point of view of economy, it is important that the mixing shall not be unnecessarily prolonged. The mixing is either accomplished on the construction site or the ready-mixed concrete is transported there from central mixing plants. In these plants, usually proportioning and mixing are accomplished and the mix is shipped to the site in special agitator trucks, which prevent the segregation of aggregates during the transport. The ingredients can also be placed in the trucks without mixing, and then the mixing takes place during the shipping.

Transportation.—The design of the mix is also governed by the means and type of equipment which are used to transport the mix from the plant into the formwork. The simplest means of transportation are buggies and wheelbarrows, but more extensive and complex constructions usually require chuting equipment. The workability of the concrete, the character of the materials used, and the design of the chute determine the most suitable slope of the chute. It is recommended that the slope of the chute shall be not less than 1 to 3 and not more than 1 to 2. Concrete should not fall freely more than a few feet; neither should it be shot out at an angle. The purpose of the above recommendations is to prevent the segregation of ingredients during the transportation.

Placing.—This element of the cycle of concrete fabrication requires great care. Here again caution must be exercised to avoid segregation of the mix. It must be ascertained that the concrete fills out the whole framework uniformly and densely without forming honeycombs. Constant supervision during the entire operation is essential. Flowing over long distances will cause segregation of the water and the mortar. In placing concrete in deep layers a gradual increase in the water content of the upper portions as the result of the increased pressure on the lower portions is unavoidable. This excess water should be brought to a low point and removed. Light tapping of the forms or spading of the concrete will prevent honeycombing and also make surface finishing easier. The so-called layer of laitance should be avoided, because this is a sign of excess water. If it cannot be

avoided, it should be removed to prevent poros concrete. Vibrators are quite frequently used, but it has to be kept in mind that vibration in itself does not increase the strength of the concrete. The effect of the vibration increases the workability; therefore the use of vibrators permits the use of stiffer mixes and lower sand content and thus allows the use of either less water or leaner mix. The convenience of vibrators for placing concrete under adverse conditions is important. It permits the concrete to flow through small openings or around closely placed reinforcement. If stiffer and harder mixes than ordinarily practicable are used with vibrators, the following benefits can be obtained: increased strength; increased density; lower absorption; increased resistance to weathering; better bond between successive layers and also between concrete and reinforcement; less volume change, especially from plastic to hardened stages. Most of the high frequency vibrators give not less than 3,600 impulses per minute. They may be electrically operated or by gasoline engine or air compressor. They are of three general types: internal, form, and surface vibrators.

Concrete is usually placed into formwork, the purpose of which is to support the concrete and keep it in its desired shape until it is sufficiently hardened and has gained sufficient strength. The cost of the formwork might represent as much as 15 to 40 per cent of the total cost of the concrete structure. The material most commonly used in the formwork is spruce and pine wood in such forms as boards and studs. Besides ordinary lumber, the following materials are used: plywood in panel forms, panels of compressed wood fibers, steel, plaster, and glue forms. The formwork has to be carefully designed in order to support the plastic or semifluid concrete without great deformations; it has to be tight enough to prevent leakage. Sometimes a coating of mineral oil is used to improve the surface of the finished concrete to prevent the absorption of the mixing water and to facilitate the removal of the form itself. The time that the formwork has to remain in place depends on the following conditions: the type of the structural members; the character of concrete and weather conditions, such as relative humidity and especially temperature. The rule to follow for the removal of forms is that they should be removed after the concrete has hardened sufficiently to support its own weight. The actual time the formwork is left in place varies from one to two days for walls and columns to seven or more days for slabs and girders and for members which at the time of stripping carry other loads besides their own weight.

Besides the placing of concrete, in reinforced concrete work the placing of the reinforcement presents special problems. It is of great importance that the reinforcing bars be placed accurately and held in place securely during the placing operation of the concrete. Small errors in the position of the reinforcement might increase considerably the stresses in a member above those calculated. There are several devices to hold the steel securely and at proper distance from the forms. The components of the reinforcement should be secured to each other by wires or by welding. The reinforcement should not be placed directly on the formwork but on precast concrete blocks or steel "chairs."

Curing.—The process of hardening in the concrete continues indefinitely as long as moisture is present and temperature is not low. As continued hardening of concrete increases its strength, water-tightness, and wear resistance, it is important to keep newly placed concrete as long as possible under conditions which permit this process. The maintaining of this process is called curing. As the fresh, or as it is often called "green," concrete contains an excess water above what would be required for hydration, the process of curing essentially consists in the preventing of the evaporation of this water for a certain time. Exposed surfaces should be protected from drying out for at least seven days. This can be accomplished by placing wet burlap, straw or canvas covering on finished surfaces, and by wetting it or even keeping it flooded with water for a certain period. Vertical surfaces are protected by leaving the forms as long as possible, or by sprinkling or hanging wet canvas over the surface. The temperature has a great influence on the success of the curing. At temperatures near freezing concrete gains very little in strength and the hardening process stops, but if the concrete is heated again to normal temperatures, the strength will increase and if kept moist, the whole potential strength might be regained.

Follow-up Tests.—The purpose of these tests is to determine the effectiveness of the field control methods. The test can be classified into tests made on specimens of concrete used on the job and load tests. Tests made on concrete specimens are usually compression tests, that is, the determination of the compressive strength of the concrete. These tests have to follow procedures established by the ASTM and consist of preparing specimens of concrete in a form of a cylinder usually 6 inches in diameter and 12 inches high. These cylinders are then subjected to compression in a testing machine until breaking. The load required to break the test cylinder is used as the measure of the compressive strength of the concrete. It is usually required that not less than three specimens shall be made from each test and one test for each 250 cubic yards of concrete. The average strength of the test cylinders should not fall below the minimum ultimate compressive strength called for in the plans.

Load tests are sometimes required for certain portions of the building when the strength of the test specimens falls below those specified in the plans or, if for other reasons, doubt exists about the soundness of the structure. The load test consists of superimposing on a portion or on a member of the finished structure loads, which are left in place for 24 hours. The structure is considered having passed the test if the deflections observed at the end of the test period do not exceed certain specified values, and the load set, that is, the permanent deflection, after removal of the loads does not exceed a certain precentage of the total deflection. The American Concrete Institute in its *Building Regulations for Concrete* specifies that the superimposed load shall be equal to one and one-half times the live load plus one half of the dead load. The maximum deflection shall not exceed the value expressed in the following formula: $D = 0.001 \times L^2/12 \times t$ where D is the deflection, L the span of the member, and t the total depth of the member

tested. The structure should show a recovery of at least 75 per cent of the observed deflection.

Physical and Chemical Characteristics of Concrete.—The main value of concrete as structural material is its relatively high compressive strength and shear strength, and its bond strength. Besides its strength qualities, its durability, resistance to weathering and fire-resisting properties, and its low permeability are its most important positive characteristics. Fairly good thermal and accoustical insulating properties can also be attributed to concrete. The weakness of concrete consists in its low tensile strength, its elastic and plastic action under loads, and the volumetric changes which it suffers when subjected to moisture and temperature variations. Concrete is properly used if its advantageous characteristics are fully exploited and the effect of its negative characteristics reduced to a minimum. Most of the physical characteristics of concrete are interdependent and the compressive strength can be conveniently used as a measure of its general qualities.

Compressive Strength.—This depends as previously stated on the following: quality and proportioning of ingredients (especially water-cement ratio), and aging under favorable conditions. The ultimate compressive strength of concrete at 28 days varies between 2,000 and 3,750 pounds per square inch for ordinary concrete or reinforced concrete work. In unimportant mass work it is sometimes used with a strength as low as 1,500 pounds per square inch, and for columns carrying heavy loads, compressive strength as high as 6,000 pounds per square inch might be required.

Tensile Strength.—Concrete is weak in tension. Its tensile strength is one fifth to one tenth to its compressive strength. In reinforced concrete design the tensile strength is usually completely disregarded, by taking up all tension through reinforcing bars. The tensile strength sometimes is expressed in the form of the modulus of rupture which is the computed tensile stress at the outer fiber at the time of rupture of a plain concrete beam loaded transversally.

Shear Strength.—Concrete is only rarely used to resist pure shear. It is also difficult to be tested for such conditions. Available test results indicate that its shear strength is normally not less than half of its compressive strength. The term "shear" is often used in concrete design in a meaning which can be misinterpreted. The diagonal tensile stresses existing in members subjected to flexure are numerically equal to the shear stresses computed for those conditions. These tensile stresses are often referred to as shear.

Bond Strength.—The adhesion of concrete to the reinforcing bars makes the use of reinforced concrete possible. This adhesion is referred to as bond, that is, the resistance against slipping between steel and concrete when subject to loads. Tests indicate that slip between reinforcing bars and concrete occurs when the bond stress reaches a value up to 15 per cent of the compressive strength of the concrete, but the maximum resistance is reached after a certain amount of slip has occurred. The bond strength can be substantially increased by the use of deformed bars. Slipping is also resisted by hooking the ends of reinforcing bars. Square bars offer lower resistance than plain round ones.

Elastic Properties.—Concrete subjected to compression does not deform in direct proportion to the amount of compressive stresses; that is, the stress-strain relation is curvilinear. As the curvature of the stress-strain curve at low stresses is very small for ordinary working stresses, a straight line stress-strain relationship can be assumed with sufficient exactitude. Therefore as the slope of the stress-strain curve represents the modulus of elasticity, this value is usually taken as constant, and set by some authorities at 3,000,000 pounds per square inch. Actually there exists here again a direct relationship between the ultimate compressive strength and the modulus of elasticity. This relationship based on tests can be expressed as follows: $E_c = 1{,}800{,}000 + 460\ f'_c$ in which E_c is the modulus of elasticity of concrete and f'_c is the ultimate compressive strength of concrete at the age of 28 days. The American Concrete Institute recommends for design purposes the following formula: $E_c = 1{,}000\ f'_c$.

An important elastic property of concrete is its plastic flow. When concrete is subjected to sustained loading, it continues to deform or flow plastically for a long period. Experiments indicate that the amount of plastic flow is approximately proportional to the stress to which the member is subjected, and that it gradually decreases and approaches a constant rate after the load has been applied. Plastic flow depends also on the following factors: age of concrete, humidity of the air, amount of cement paste in concrete, and characteristics of aggregates. The importance of plastic flow has been recognized since about 1936.

The strength of concrete decreases under repeated stresses. The fatigue limit of plain concrete is about one half of its ultimate static compressive strength.

Permeability and Durability.—The permeability of concrete is affected by the cement paste composition in the same way as the compressive strength. Also, the following factors influence it: curing, placing, amount of cement paste and special admixtures to decrease permeability, such as pulverized sand and fine clay. Durability is closely related to the permeability of concrete.

Volumetric Changes.—One of the most adverse properties of concrete is that it shrinks during the process of hardening. It is of great importance to reduce this shrinkage to a minimum. It has to be understood that the shrinking of concrete, although it takes place mostly during the hardening, is not necessarily caused by the hardening. The change of volume due to the variation of moisture content results either in shrinkage or in quelling. Cracks are formed in restrained concrete as a result of shrinkage and insufficient tensile strength, while it can easily withstand compressive stresses due to quelling. Durability is also affected by cracking as it permits the easy ingress of percolating waters and brings about leaching, corrosion of steel and concrete. Volume changes due to moisture are increased by increasing the amount of cement paste in the concrete. Rich mixes and mixes of high water content are conducive to great volume changes. The disintegrating effect of volume changes due to temperature variations is materially not different from that caused by wetting and drying. However, the volume changes due to temperature are affected by both aggregate and cement paste.

The thermal coefficient of expansion and contraction increases slightly with increasing cement content and decreasing water-cement ratio. The thermal coefficient varies considerably with the type of aggregate used. In general, tap rock and granite have lower thermal coefficients than quartz and sandstone. Concrete made from aggregates in which the particles are not of uniform thermal characteristics or which have a thermal characteristic different from hardened paste, is more subject to the destructive effect of temperature variations. The average value of the linear thermal expansion coefficient of concrete is 0.0000055 per degree Fahrenheit of temperature difference per unit length. This value is very close to the coefficient of steel and therefore temperature changes do not cause appreciable bond stresses between steel and concrete.

Fire Resistance.—There are two important criterions of fire resistance: (1) the cement content, and (2) the characteristics of the aggregates. The same factors affect the fireproofness as affect the compressive strength—concrete of greater strength has also greater fireproofness. However, the effect of the aggregates is more prominent. Artificial lightweight aggregates and water-cooled slag are especially well suited for fire-resistant concrete. In general, lightweight porous aggregates are more favorable than ordinary gravel or limestone.

Resistance to Chemical Attack.—The following table prepared by the Joint Committee on Standard Specifications for Concrete and Reinforced Congrete gives the effect of chemicals on unprotected concrete:

Substance	Effect
Petroleum oils—heavy, light and volatile	None
Coal tar distillates	None or very slightly
Inorganic acids	Disintegration
Organic Materials:	
Acetic acid	Slow disintegration
Oxalic and dry carbonic acids	None
Carbonic acid in water	Slow attack
Lactic and tannic acids	Slow attack
Vegetable oils	Slight or very slight attack
Inorganic Salts:	
Sulphates of calcium, sodium, magnesium, potassium, aluminum, iron	Active attack
Chloride of sodium, patossium, calcium	None
Chloride of magnesium	Slight attack
Miscellaneous:	
Milk	Slow attack
Silage juices	Slow attack
Sugar solution	Active attack

Structural Design of Concrete and Reinforced Concrete Members.—The design of concrete structures is a specialized field. It involves, besides the mastering of the general field of statics and strength of materials, an intimate knowledge of the statics of continuous rigid structures and the resistance of composite sections. Statically concrete structures are, with exceptions, continuous beams, girders, and slabs or rigid bents, and multistory frames and various types of arches, plates and shells, and columns.

The material is composite, that is, it is made up of two distinct materials (steel and concrete), both of which participate actively in resisting loads and therefore the induced stresses are distributed between them in certain proportions. The design is usually based on certain simplified assumptions, which correspond only partially to the true conditions. It is usually also assumed that in portions of members subject to tension, the steel alone will resist all tensile stresses, while in portions subject to compression, either the concrete alone resists the compressive stresses or, if steel is employed, the stresses are resisted in the ratio of the elastic moduli of the materials. This is the usual hypothesis underlying the design of most composite members.

The working of reinforced members can be best understood by studying the characteristics of a plain (not reinforced) concrete beam subject to exterior loads. Under the action of these loads as the beam deflects, cracks will develop at the lower edges of the beam, due to the low tensile strength of concrete. These cracks will run near the center of the beam perpendicularly to its span and near the supports will be inclined toward them under an angle of approximately 45°. In order to diminish these tensile cracks, reinforcing bars are placed in these locations, which are of three types: (1) longitudinal reinforcements—these are placed longitudinally in the lower portion of the beam and they tend to reduce the cracks running perpendicular to them; (2) bent up reinforcement—parts of the longitudinal reinforcement is bent up usually under 45° toward the supports. These bars reduce the inclined cracks which run also approximately perpendicular to their direction. (3) stirrups—these consist of bars bent usually in U-shape, enclosing the longitudinal reinforcement running upward near both vertical sides of the beam. The purpose of these is to tie the longitudinal reinforcement securely to the compressed part of the beam, besides reducing the inclined cracks. In beams which run continuously over more than two supports, longitudinal reinforcement on the top of the beam over the supports is placed in addition to the ones at the bottom near the center of the span, as the upper side of the beam is in tension at these places. Cantilevered beams have longitudinal reinforcement only on the upper side. All the above described types are typical reinforced beam constructions. Reinforced one-way slabs are, in principle, beams the width of which is very large in proportion to its depth. Therefore the reinforcement is in principle similar to the one placed in beams, except that stirrups are omitted but so-called temperature reinforcement is placed perpendicularly to the principal (longitudinal) reinforcement. The objects of the temperature reinforcement are to distribute loads across the width of the slab and to reduce cracks caused by changes of temperature and moisture content. In both slabs and beams sometimes it is found necessary to place reinforcement into the compression zone of the concrete, if the depth of the members has to be reduced. Compression reinforcement is generally not economic and not characteristic to reinforced concrete members. Beams and slabs occur usually simultaneously in reinforced concrete construction and are poured homogeneously. Therefore the beam when subject to a load will be aided in resisting it by a certain portion of the slab. This produces the so-called T-section which is so characteristic of reinforced concrete beams. In the T-section the extended upper part of the T, the flange, is subject to compression, while

the narrow lower part of the web is subject to tension and therefore reinforced.

Slabs can be supported on four edges and the resulting structure is usually termed two-way slab. In this type the principal reinforcement runs both ways parallel to the edges of the slab, thereby reducing its depth.

Slabs can be supported on columns only. The resulting construction is termed flat slab which was previously described. All the above structural members are subject to bending only.

Another typical group is represented by members subject to compression only, and these are usually called columns. In columns, both steel and concrete participate in resisting compression stresses. The reinforcement is placed longitudinally, evenly distributed near the surface of the column and it is held in place by ties which are similar to stirrups in beams, but do not participate in resisting loads. Heavily loaded columns are reinforced besides longitudinal members with so-called spiral reinforcement, consisting of thinner reinforcing bars or wires wound around the longitudinal reinforcement. This type of reinforcement was invented by the French engineer Armand Considère. It was found that the spiral reinforcement is 2.4 times as effective as when the same amount of reinforcement is placed longitudinally.

Besides members which are subject to compression or to bending alone, there exists a group which is subjected simultaneously to action of both types. The resulting reinforcement is essentially a combination of the types described above. The most typical structures of this type are arches, rigid frames, and columns subject to eccentric loads.

All structural members are one of the three types described above, disregarding their function or particular shape, of which there can be a great variety in reinforced concrete structures.

The design of concrete and reinforced concrete structures is regulated by various building codes and regulations. The subject of these codes is to establish the conditions under which these constructions can be safely used. In the following section some of the recommendations of the *Building Regulations for Reinforced Concrete,* adopted in 1941 by the American Concrete Institute (ACI) are discussed.

Allowable Working Stresses.—In order to obtain a safe design, it is necessary to subject the materials to loads which will cause stresses below the ultimate strength of the material. The ACI code recommends that the following working stresses be used, expressed in percentage of the ultimate compressive strength at age of 28 days.

Type of stress	Percentage of ultimate strength
Extreme fiber stress in compression	45.00
Shear—in beams with properly designed web reinforcement and with special anchorage of longitudinal steel	12.00
Bond in beams and slabs with deformed bars	5.00

The actual working stress in compression usually varies between 900 and 1,700 pounds per square inch in ordinary reinforced concrete construction. The allowable unit tensile stress in reinforcing bars varies according to the grade from 18,000 pounds per square inch to 20,000 pounds per square inch; some codes go up to 24,000 pounds per square inch.

The reinforcement in important structural members which are deposited against the ground has to be protected with at least 3 inches of concrete. If the concrete surface is exposed to weather, the protecting concrete is recommended to be 2 inches for bars more than ⅝ inch in diameter, and for bars of lesser diameter a protection of 1½ inches is required. In surfaces not exposed to weather the protection should be ¾ inch for slabs and walls and 1½ inches for beams and columns. The minimum amount of reinforcement which must be placed in various members is also specified. It is expressed in percentages of the total net section of the concrete member: longitudinal reinforcement 0.50 per cent in beams and girders, 0.25 per cent in slabs. The temperature reinforcement in slabs has to be not less than 0.25 per cent if plain bars and 0.20 per cent if deformed bars are used. The reinforcing bars have to be anchored by bond or hooks or mechanical anchors.

In the design of columns the allowable stress is dependent also on the unsupported length of the column, as this influences its stability. Usually columns are such that the unsupported length is not greater than 10 times its least dimension. These columns are termed short columns. Principal columns should have a minimal diameter of 12 inches or, if rectangular, a minimum thickness of 10 inches. In short tied columns, the minimum reinforcement is 1.0 per cent and the maximum 4.00 per cent; in spirally reinforced columns, the area of the vertical reinforcement should be not less than 1.0 per cent and not more than 8.0 per cent.

The above data represents only some of the most important and typical recommendations of the code. All structural design work should be done strictly in accordance with the adopted code.

Chief Technical Consultant, National Housing Agency.

CONCRETE SHIPS. The first example of reinforced concrete ships was a rowboat built in 1849 by M. Lambot, of Carces, France. The process of construction was patented and M. Lambot exhibited his work at the Paris Exposition of 1855. In 1899, Carlo Gabellini, of Rome, Italy, began the construction of concrete scows and barges. His process had been so developed by 1905 that a 150-ton barge was constructed for the city of Civita Vecchia.

Methods of Construction.—In the Gabellini method the first step in "laying down" these vessels consists of placing reinforcement for the keel and ribs. A somewhat thinner coat of mortar is placed on the inside, following which forms for the ribs and keel are put in place and concrete deposited for these parts of the vessel. These ribs run both longitudinally and transversely, pockets being 10 inches deep and the ribs about 2 inches wide. Over

these ribs ½-inch wire mesh is placed with a thin mortar covering plastered on. Finally a third and coarser wire mesh is pressed into the soft mortar and the entire surface troweled over. This completes the hull. Bulkheads are next concreted and the boat finished with a wooden sheer strake and gunwale.

The first concrete boat in Holland was built in 1887 by the Fabrieck van Cementljzer Werken. This firm first built barges up to 11 tons capacity, which proved so successful that plans were elaborated resulting in the building of barges 64 feet long and 14 feet beam, of 55 tons capacity. Briefly, the system of construction consisted of building longitudinal and transverse bulkheads spaced approximately on 6-foot centres, thus providing a cellular construction, which made the ship practically unsinkable. German shipbuilders, in 1909, at Frankfort-on-the-Main, constructed a concrete freighter of 220 tons. Simple forms were set up and concrete placed between them. A concrete sailboat was built in 1912 by Johannes Lescher of Dresden. It embodied the latest principles of sailing vessel construction as to shape of hull, etc. In 1914 the Sydney Harbor Trust had constructed a pontoon of reinforced concrete for use in Sydney Harbor, N. S. W. It is 110 feet long, 53 feet 3 inches wide at the bow, 67 feet 7 inches at the stern, has a draft of 7 feet 9 inches and deck area of 6,000 square feet. The total displacement is 783 tons. Concrete barges have been in use for some years on the Manchester Ship Canal, and one on the Welland Canal has successfully withstood very severe tests since its installation in 1910. Concrete barges built on the Panama Canal in 1911 proved good examples of what service such barges could render under adverse conditions. In this case concrete was selected as the construction material because no skilled labor for steel or wood ship construction was available, nor could steel plates nor suitable seasoned timber be obtained within the time required. Concreting materials were at hand in large quantity and the expediency of using concrete suggested itself as a happy solution of the problem. Concrete barges have been constructed also and placed in successful operation at Baltimore, Md., and Mobile, Ala.

In 1917 a concrete lighter was built at Porsgrund, Norway, and its success led to the construction of larger ships at the same plant. In the same year a 300-ton concrete motorship was built in England for coastwise and channel traffic. At the end of the first half of 1917, 20 or more barges and ships of similar type were in use on the Paris ship canal. Canada came forward in the same year with a concrete ship proposed for lake traffic. A concrete ship approximating 5,000 tons was built for trans-Pacific service at Redwood City, Cal., in 1917, and a New York company in the same year built a 700-ton concrete barge, and in 1918 had contracts in hand and work progressing on a number of similar vessels. Norway came to the forefront in this field in 1917 in the numbers of concrete barges, lighters and ships varying from 200 tons up to 3,000 tons, launched. Some of these are in ocean traffic between Norway and England. The year 1918 saw rapid advances in the construction of concrete ships, due to the great necessity of overcoming the losses in merchant tonnage through Germany's submarine warfare. This development was chronicled at length in the daily press and in the periodicals of the era. Consult 'Concrete Ships' (issued by the Portland Cement Association, Chicago 1918), from which the foregoing account has been compiled; *Concrete and Constructional Engineering* (Vols. XI, XII, XIII, London 1916–18); *Marine Review* (Cleveland, August 1917); *Scientific American* (28 July 1917; 17 Nov. 1917); *Shipping Illustrated* (New York, 23 June 1914; 18 Aug. 1917; 29 Sept. 1917; 20 Oct. 1917); *The London Times* (Engineering Supplement, 25 May 1917).

CONCRETION (the act of growing together), the act of becoming united into one mass. (1) *In a restricted sense* the term is used to signify a solid mass, a clot or a lump formed by a process of growing together, as in animal economy, the hard substances that occasionally make their appearance in different parts of the body, as well in the solids as in those cavities destined to contain fluids; in the former case they are denominated concretions or ossifications; in the latter, calculi. The concretions are named from the parts of the body in which they occur. Pineal concretions, from their being found in that part of the brain called the pineal gland, consist of carbonate and phosphate of calcium with organic matter; salivary concretions, as being discovered occasionally in the salivary glands, also consist mainly of earthy phosphates; pancreatic concretions are hard substances found in the pancreas; pulmonary concretions, which have been sometimes coughed up by consumptive persons, contain mucus and albumen in addition to the salts; hepatic concretions, of which the liver is sometimes full, are composed chiefly of cholesterin, mucus and coloring matter; urinary concretions are found in the bladder, and their constituents are very variable, uric acid, urates, fibrin, oxalates, phosphates and several other bodies being found. Gouty concretions consist of urate of sodium and small quantities of other salts with organic matter. Concretions have been discovered in the intestines and stomach of man, but more frequently in the bodies of other animals. Those found in the intestines of a horse were examined by Fourcroy, and found to consist of magnesia, phosphoric acid, ammonia, water and animal matter. (See CALCULUS). (2) *In geology* concretion signifies an aggregation of mineral matter, in concentric layers and cast in a spherical form which is frequently flattened, (3) *In logic* concretion is the act of rendering a concept more determinate or concrete.

CONCRETIONS, masses of mineral matter, sometimes arranged in concentric layers, sometimes with a radiating structure, sometimes almost structureless, which have been built up particle by particle by circulating waters within the mass of another rock. Most concretions are circular or nearly so, but sometimes they occur in irregular shapes. Concretions of flint are common in limestone, and concretionary masses of iron pyrites frequently occur in coal. They vary greatly in size ranging from a fraction of an inch to several feet.

CONCUBINAGE, the act or practice of cohabiting without a legal marriage; the state of being a concubine; a natural marriage as distinguished from a legal marriage. Among

the Greeks concubinage was allowed even to married men: the number of their concubines, also, was unlimited. Among the Romans concubinage was neither unlawful nor disgraceful. It was, moreover, formally permitted to unmarried men by the Lex Julia, and by the Lex Papia Poppæa, but with the provision that it should be limited to a single concubine, and that only women of mean descent, as freed women, actresses and the like, should be chosen for the purpose. The children begotten in concubinage were not considered as legitimate, but were called natural, and the right of inheritance of the concubine and her children was very much limited. With the introduction of Christianity concubinage ceased; and, indeed, Constantine the Great made laws intended to put a stop to it. Concubinage also signifies a marriage with a woman of inferior condition, to whom the husband does not convey his rank. By French law the presence of a concubine in the house entitles the wife to a divorce. See MARRIAGE.

CONCURRENT JURISDICTION, the jurisdiction of different courts authorized to take cognizance of the same case. In criminal cases the court which first takes up a case has what is called the right of prevention, that is, the right of deciding upon that case exclusive of the other courts, which but for that right would have been equally entitled to take cognizance of it. In civil cases it lies with the suitor to bring his cause before any court he pleases, which is competent to take it up. Concurrent, also called cumulative, jurisdiction is opposed to privative jurisdiction. Where concurrent jurisdiction exists in the United States courts a decision of a State court may be taken up to the Supreme Court for review.

CONCUSSION OF THE BRAIN, a term applied to certain injuries of the brain resulting from blows and falls, though unattended with fracture of the skull. Stupor or insensibility, sickness, impeded respiration and irregular pulse are the first symptoms, and though these may subside there is always for a time more or less risk of serious inflammation of the brain setting in. Although all the conditions attending concussion of the brain have been carefully studied experimentally, yet authorities disagree as to the causes which induce it. These causes have been variously stated as laceration of minute blood vessels, molecular changes in the brain cells or changes in the cerebrospinal fluid. The patient should be put to bed at once with the head low, and kept warm; but stimulants should, except in special cases, be withheld. All excitement should be avoided, and for some time after apparent recovery great care is necessary.

CONDÉ, kôn-dā, the name of a French family, the younger branch of the Bourbons, who took their name from the town of Condé, department of Nord. One Godfrey de Condé, about 1200, was in possession of a part of the barony of Condé. His great-granddaughter, Jeanne de Condé, married, in 1335, Jacques de Bourbon, Comte de la Marche, and the barony of Condé went to their second son, Louis de Bourbon, Comte de Vendôme, whose great-grandson, Louis de Bourbon, Prince of Condé, in virtue of his blood-relationship to the royal family, assumed the title of Prince, and is regarded as the founder of the new house of this name.

CONDÉ, Henri (ŏn-rē) **II de Bourbon,** PRINCE DE: b. 1588; d. 1646. At the request of Henry IV he became a Catholic. In 1616 he was sent to the Bastile, where he remained for three years. After the death of Louis XIII the prince was liberated, and was made Minister of State to the regent.

CONDÉ, Louis (loo-ē) **I de Bourbon,** boor bôn, PRINCE DE, French general: b. Vendôme, 7 May 1530; d. 15 May 1569. He married the grandniece of the Constable de Montmorenci. He served his early campaigns in Piedmont, but first distinguished himself at the defense of Metz, besieged by Charles V in 1552. Affronted at court, and hated by the Guises, he joined his brother, the king of Navarre, at Nérac, and joined the Huguenots in 1559. In 1560 he took part in the Amboise conspiracy to overthrow the Guises. He was arrested and sentenced to death, but was discharged after the death of Francis I and was made governor of Picardy through the influence of Catherine de Medici (q.v.) who was then all powerful in France. He soon after appeared as head of the Protestants, and was defeated and captured at the battle of Dreux, 1562. After being over a year in prison he was liberated, and for four years he kept the peace but fresh persecution of the Huguenots called him to arms again. In 1567 he fought the battle of Saint Denis without decisive result. Two years later the Protestants were defeated, and Condé was taken prisoner, badly wounded, at the battle of Jarnac, 13 March 1569. He was almost immediately assassinated by Captain Montesquieu, a Swiss soldier who was probably acting under orders from the Duke of Anjou. See COLIGNY, GASPARD DE.

CONDE, Louis II de Bourbon, PRINCE OF, French general: b. Paris, 8 Sept. 1621; d. near Fontainebleau, 11 Dec. 1686. He was the son of Henri II, Prince de Condé (q.v.) and during the life of his father bore the title of Duc d'Enghien. He immortalized this name at the battle of Rocroi, in which, at the age of 22, he defeated the Spaniards (1643). The same year he was sent to Alsace to help Turenne. Wherever he appeared he was victorious. He besieged Dunkirk in sight of the Spanish army, and gained this place for France in 1646. The death of his father in this year made him head of the Condé family with all its vast wealth and extensive estates; so that there were in the kingdom only the king himself and the Duke of Orleans who were more important personages than he. He was given command of the army in the Netherlands and appointed captain-general of the French forces. A great victory at Leas in 1648 won him a wonderful reputation. During the troubles of the Fronde he at first took the side of the court against the Parliament and the nobles, and after a siege of a few months brought back the young Louis XIV to Paris (1649); but believing himself ill requited by Mazarin for his services he put himself at the head of the faction of the *Petits Maîtres.* Being captured, however, he was imprisoned by Mazarin (1650), and was not released till after the lapse of a year. He at once put himself at the head of a new Fronde, and entered upon

negotiations with Spain. In spite of several checks he then marched upon Paris, where he was met and opposed in the suburb Saint Antoine (1652). The battle which ensued was indecisive; and Condé, finding himself abandoned by many of his friends, retired to the Netherlands, and joined the Spaniards, who appointed him generalissimo of the Spanish armies. In 1658 he was defeated before Dunkirk, by Turenne, and was only restored to royal favor by the Peace of the Pyrenees in 1659. In 1668 he was charged with the reduction of Franche Comté (then belonging to Spain), which he accomplished in three weeks; and in 1674, at the head of an army sent by Louis XIV against the United Provinces, defeated the Prince of Orange (afterward William III of England) at Senef. He was unable, however, to take advantage of this victory, as he was obliged to withdraw into Alsace to defend it against Montecuculi, to whom it was thrown open by the death of Turenne in 1675. He succeeded in driving Montecuculi across the Rhine. This was his last triumph. Four years later he retired to Chantilly, near Paris, where he devoted himself to the sciences.

CONDE, Louis Joseph de Bourbon, PRINCE OF: b. Chantilly, 9 Aug. 1736; d. Paris, 13 May 1818. In the Seven Years' War he distinguished himself by his courage and skill, and at the outbreak of the Revolution he sided with the monarchy and afterward formed in 1792, at Worms, a little corps of emigrant nobility, which joined the Austrian army under Wurmser. In 1795 he entered with his corps into the English service. In 1797 he entered the Russian service, but in 1800, after the separation of Russia from the coalition, reentered the English service. The campaign of 1800 ended the military career of the prince. He returned to Paris in 1814; where, being appointed president of a bureau of the Chamber of Peers, he remained some time, but at last retired to Chantilly. He published 'Essai sur la Vie du Grand Condé, par L. J. de Bourbon, son 4me Descendant' (1806).

CONDELL, kŭn'dĕl, **Henry,** English actor: d. Fulham, England, December 1627. With John Heming he edited the famous first edition of Shakespeare's plays, 1623. He belonged, as did Shakespeare, to the lord chamberlain's company of players and is named in Shakespeare's will.

CONDENSATION, the reduction of anything to another and denser form, as of a vapor or gas to a liquid, or a liquid to a solid; the passage of gases or vapors from the aëriform to the liquid state. It is sometimes called also the liquefaction of vapors. It may be due to one of three causes: cooling, compression or chemical affinity. Before the first or second of these causes can operate, the vapor must be saturated. Various salts also condense vapors by means of chemical affinity. When vapors are condensed their latent heat becomes free. The condensation of liquids is the reduction of a liquid to smaller bulk, with a proportionate increase in the specific gravity.

CONDENSED MILK as generally manufactured and sold fresh daily for delivery to consumers is pure cow's milk reduced in volume by the evaporation of water in vacuum. No other constituent part of the milk is removed. This article is not put up in hermetically sealed cans nor intended for long-distance shipments.

Sweetened condensed milk is the product resulting from the evaporation of a considerable portion of water from milk to which sugar (sucrose) has been added for the purpose of preservation. It contains not less than 28 per cent of milk solids and not less than 8 per cent of milk fat.

Sweetened condensed skimmed milk is the product resulting from the evaporation of a considerable portion of the water from milk from which the greater part of the milk fat has been removed and to which sugar (sucrose) has been added for the purpose of preservation. It contains not less than 28 per cent of milk solids.

Evaporated milk is the product resulting from the evaporation of a considerable portion of the water from milk and contains not less than 25.5 per cent of milk solids and not less than 7.8 per cent of milk fat.

Evaporated skimmed milk is the product resulting from the evaporation of a considerable portion of the water from milk from which the greater part of the milk fat has been removed. It contains not less than 22.5 per cent of milk solids.

Early Experiments.— The first application of a practical process for condensing milk was made by Gail Borden, who was born in Norwich, N. Y., in 1801, and at the time of his experiments a resident of New York, through his adaptation of the vacuum evaporating process on original lines. Most of the earlier experiments of previous investigators were what might be called «open process.» The earliest known patents for reducing the volume of milk or attempting to preserve it are the following:

Newton, 1835.— For evaporating in " any known mode " alludes to the vacuum pan as affording a good method of introducing warm air through the milk.

De Lignac, 1847.— Evaporating in large, flat, shallow pans, heated by steam bath to 186° F., product put in tins, sealed and again heated to 210° F.

Grimwade, 1847.— Preserving milk by " the mixing of saltpetre with the milk, and then exposing it to heat in vacuo, so as to evaporate and extract the aqueous particles thereof " and then enclosing " in bottles from which the air has been previously exhausted." Never put in practice.

Louis, 1848.— Evaporating in shallow pans, with steam jackets, etc.

Grimwade, 1855.— Carbonate of soda or potash is first added and the milk then evaporated in pans with agitation until a doughlike substance is obtained, sugar is then added, and the mass pressed by rollers into ribbons, further dried and then pulverized. Practised for some years.

Cook, 1855.— Evaporating in steam evaporating pans.

Borden, 1856.— In vacuo, put into successful practice and has superseded all others.

House, 1857.— Substantially like De Lignac's, except evaporating at lower temperature.

Gail Borden's experiments began shortly after 1851 and his first application for a United States patent was made in 1853 which was at first rejected on the ground that it lacked novelty and usefulness. The patent, however (No. 15,553), was granted 19 Aug. 1856, on the following claim:

Producing concentrated sweet milk by evaporation in vacuo, substantially as set forth, the same having no sugar or other foreign matter mixed with it.

This was followed by other patents: No. 1,306 dated 13 May 1862; No. 1,389 dated 10 Feb. 1863; No. 2,103 dated 14 Nov. 1865; No. 2,226 dated 17 April 1866.

Every feature of Borden's various claims as well as the state of the art was carefully and thoroughly investigated by the patent office examiners.

Necessary Sanitary Regulations.— Experience covering a period of over half a century establishes the fact that the sanitary precautions surrounding the manufacture of condensed milk, evaporated milk, etc., are the most stringent, and necessarily so, because the safety of the business depends upon thoroughness. Not only are the cattle inspected by competent veterinaries, but rules and regulations of the strictest kind provide for the cleanliness of these cattle, proper feeding of wholesome, non-fermenting foods, cleanliness of stables, the isolation of the milk room, cooling facilities, in fact every well-tested plan that facilitates the production of pure rich milk handled in the most cleanly manner. While seemingly these rigid requirements involve some extra expense on the part of the dairyman, he is more than compensated by having a steady, firm market for his product at better prices than he can get anywhere else. The consumer is benefited by obtaining a pure and uncontaminated product at a most reasonable price. There are of course, concerns in the business whose facilities and experience do not enable them to perform all of this work as thoroughly as those concerns, which have been established for many years.

The receiving platform is an interesting sight, for as the farmers deliver their cans of milk, each is examined by a trained inspector and tested. If it is not found to be up to the standard of the company, it is rejected. From the receiving room, the milk is drawn into what is called the «well room» where preliminary heating is effected in specially designed heating wells. If sweetened condensed milk is to be made, the necessary amount of sugar is dissolved in the milk at this point. The mixture is then drawn to the vacuum pan where the condensing process takes place in accordance with formula as to temperature, vacuum, etc., as found by the manufacturers to be best qualified for making the highest grades. The concentration is continued until the density indicates the milk to be of the desired composition. It is then drawn from the vacuum pan and cooled to the proper temperature for canning, before being conveyed to the sealing room. In the case of sweetened condensed milk, the product is supplied to the filling machines which automatically deliver the exact quantity desired into the cans. These are in turn capped, sealed and labeled by machines, and are then packed in cases for transfer to the warehouse where they await shipment. If the product made, however, is evaporated milk, it is conveyed to the processing room, where the necessary sterilizing of the sealed package is performed in large steam retorts. After the cans have been cooled, they are packed in cases and sent to the storage room.

A condensed milk plant properly operated buys it supplies in large quantities; milk-sugar, tin cans or tin plate for making its cans (a factory sometimes containing a complete can-making tin-shop); lumber in shooks for making boxes; so that nearly all the work incidental to completing the product is done in the factory. Such a plant represents a large investment.

Chemical Analysis.— As condensed milk forms such a very large and important item of food, especially for the infant, it is proper in this article to incorporate information on the question of analysis that the public may be correctly informed on the subject. For some years past, the methods for the analysis of condensed and evaporated milk products have been very unsatisfactory. Unless operated by analysts of considerable experience, the results were inclined to be decidedly misleading. It is a matter of record that many chemists have erroneously reported samples of superior brands of milk as skimmed or partly skimmed, when in reality, the error was solely in the work of the analyst.

In order to clarify this situation, the Milk Section of the National Canners Association appointed a committee to develop a method of analysis which would prove satisfactory to both the milk trade and the Federal authorities. After an exhaustive survey, the Roese-Gottlieb method was finally selected as being the most accurate and reliable one available. At the same time, collaborative studies were being conducted by the Association of Official Agricultural Chemists for the purpose of finding a method which would give concordant results in the hands of any competent analyst. As a result of this work, this organization adopted the Roese-Gottlieb method at its last meeting. In order, therefore, to secure official recognition, all analysts of condensed and evaporated milk products should be guided by the above recommendation. The fact that such a satisfactory method is now in use should do much to prevent such unfortunate misrepresentations as have occurred in the past.

Food Value.— An analysis of condensed milk (preserved) of high average quality would be about as follows:

	Per cent		Per cent
Fat	9.50	Ash	1.80
Protein	8.18	Cane sugar	40.50
Milk sugar	12.30	Water	27.72

The following analysis is representative of the evaporated milk now sold on the market:

	Per cent		Per cent.
Fat	8.00	Ash	1.51
Protein	7.12	Water	72.98
Milk sugar	10.39		

Of all the foods available to the public, it is doubtful if any rank as high in purity, keeping quality and uniformity. For infant feeding, household uses, for supplying the army and navy, shipping trade, exploring parties or pioneer life, no food article prepared has greater value.

A. W. MILBURN,
Late President, Borden's Condensed Milk Co.

CONDENSER, one who or the thing which condenses. Some of the methods in general use are:

Steam-engine.— An apparatus for reducing to a liquid form the steam in front of the piston, so as to obtain a partial vacuum at that point, and thus utilize the natural pressure of the atmosphere. Watt invented the injection condenser and the separate condenser. The surface condenser has a series of flat chambers or tubes, usually the latter, in which the steam

is cooled by a body of water surrounding the tubes.

In the jet condenser the steam and water meet in an air-tight chamber. A modified form of the jet condenser, known as the siphon condenser, makes use of the Torricellian vacuum. Distilled water for ships' use is obtained by the condensation of steam in a surface condenser. Condensers are always employed on ocean-going steamships, never on locomotives. Elsewhere the practice varies.

Distilling.— The still-condenser is an apparatus generally made of the worm-tube form; the coil containing the alcoholic vapor traversing a tub which receives a constant accession of cold water, condensing the vapor in the coil. The liquid escapes at a cock valve below.

Metal.— An apartment in which metallic or deleterious gaseous fumes are condensed to prevent their escape into, and contamination of, the atmosphere. The device consists of a prolonged duct for the fumes, with showers of water to condense the arsenical, sulphurous and other fugitive volatile matters. It also serves an economical purpose in saving fugitive fumes of lead, zinc, mercury, sulphur, antimony and similar metals.

Electricity.— An instrument for concentrating electricity by the effect of induction. It usually consists of confolded sheets of tinfoil, whose layers are separated by a thin sheet having a non-conducting surface.

Other forms are the Leyden Jar, and the variable condensers made of metal sheets which can be moved in and out through an air gap, that are used in wireless telegraphy and for other similar purposes. With induction apparatus, a condenser may be used as a device for absorption or suppression of the extra current induced by the rapid breaks in the main current. See ELECTRICITY; INDUCTION.

CONDENSING AND NON-CONDENSING ENGINES. See STEAM-ENGINES.

CONDER, Claude Reignier, English army officer: b. 1848; d. 1910. He was educated at University College, London, and entered the Royal Engineers. He was chief of the Palestine survey in 1872–78 and in 1881–82. Later he served in Egypt and Bechuanaland and in 1887–94 was British commissioner at Ordnance Survey headquarters on the Transvaal border. In 1895 he was engaged in relief work in Ireland and served on the Irish Ordnance Survey from 1900 to 1905. He wrote much on the topography and archæology of Palestine. His published works include 'Tent Work in Palestine' (1878); 'Judas Maccabæus' (1883); 'Heth and Moab' (1883); 'Memoirs of the Palestine Survey' (1883; 1890); 'Primer of Bible Geography' (1884); 'Palestine' (1891); translation of the Tel el-Amarna tablets (1894); 'The Latin Kingdom of Jerusalem' (1897); 'The Hittites and their Language' (1898); 'The Rise of Man' (1908); 'The City of Jerusalem' (1909). He was also a contributor to Smith's 'Bible Dictionary' and made a series of illustrations for Bunyan's 'Pilgrim's Progress' in 1869 and made illustrations and maps for his own books.

CONDER, Josiah, Anglo-Japanese architect: b. London, 28 Sept. 1852. He was educated at the Bedford Commercial School (now the Modern School). He studied at the South Kensington Art Schools and Slade Life Classes at University College. He became architectural assistant to the late William Burges and become a student of the Royal Institute of British Architects. In 1876 he was engaged by the Japanese government as professor of architecture to the Imperial Japanese Engineering College, Tokio, and as architect of the Public Works Department. He designed and erected many government buildings and private buildings in Tokio. He also was lecturer in architecture at the Imperial Tokio University. In 1884 he received the fourth class decoration of the Rising Sun and in 1894 the third class of the Sacred Treasure. He is now retired and receives a life pension from the Japanese government, still retaining the position of honorary adviser in architecture to the Home Office and engages also in private practice. His publications include 'The Floral Art of Japan'; 'Landscape Gardening in Japan'; 'Notes on Japanese Architecture'; 'Paintings and Studies by Kawanabé Kyosai.'

CONDILLAC, kŏn-dē-yăk, **Etienne Bonnot de Mably de,** French philosopher: b. Grenoble, 30 Sept. 1715; d. Beaugency, 3 Aug. 1780. He founded an international reputation on 'The Essay on the Origin of Human Knowledge (or Sense Perceptions)' (1746); duly succeeded by the celebrated 'Treatise on the Sensations' (1754), the central standpoint of these and other works being what is, philosophically speaking, sensationalism; a belief, that is, that what we know we know only through the senses, and hence our ideas of deity, love, the soul, etc., are largely modified forms of the objects that impress us in our daily material experience. These standpoints were practically those of French philosophy till the advent of Cousin. Among his other works are 'Traite des Sensations' (1755); 'Cours d'Etudes' (1755); 'Le Commerce et le Gouvernement Considérés Relativement l'un à l'autre' (1776); 'La Logique' (1781); 'Langue des Calculs' (1798).

CONDIMENTS, substances employed at table for the purpose of imparting a flavor to or seasoning ordinary foods. The principal condiments are common salt, butter, oil, vinegar, sugar, honey, ginger, mustard, pepper, pickles, etc. These not only are pleasing to the appetite but also supply various wants of the system, many of them being necessary to the proper functioning of the alimentary system.

CONDITION, in law a statement of terms, a provision or stipulation, as in a contract, by which the parties thereto consent to be bound; or an undertaking to do something, pay money or other consideration, etc., as a proviso in an agreement by which the other parties thereto bind themselves to perform some act in return. Conditions must be made at the same time as the original conveyance or contract, but may be by a separate instrument, which is then considered as constituting one transaction with the original. Unlawful conditions are void. Conditions in restraint of marriage generally are held void; but this is not true of conditions restraining from marriage to a particular person, or restraining a widow from a second marriage. A condition in general restraint of alienation is void, but a condition restraining alienation for a limited time is good. Where

land is devised, there need be no limitation over to make the condition good, but where the subject of the devise is personalty without a limitation over, the condition, if subsequent, is held to be *in terrorem* merely, and void. But if there be a limitation over, a non-compliance with the condition devests the bequest. A limitation over must be to persons who could not take advantage of a breach. Performance should be complete and effectual. An inconsiderable casual failure to perform is not non-performance. Any one who has an interest in the estate may perform the condition, but a stranger gets no benefit by performing it. Conditions precedent, if annexed to land, are to be strictly performed, even when affecting marriage. Conditions precedent can generally be entirely performed, and usually at any rate equity will not interfere to avoid the consequences of non-performance.

The word «condition» also means the situation of every person in some one of the different orders of persons which compose the general order of society and allot to each person therein a distinct separate rank. For instance, at common law, a person under 21 is an infant, with certain disabilities and privileges. Every person is presumed to know the condition of the person with whom he deals.

CONDITIONAL IMMORTALITY, a tenet held by a theological school which denies the inherent immortality of the soul, and the consequent doctrines both of eternal misery and of Universalism as contrary to the teachings both of nature and of revelation. Its advocates maintain that the Bible sets immortality before men as something to be sought after (Rom. ii, 7), as a divine gift offered on certain conditions (Rom. vi, 23; John iii, 15, 16), and as a matter of hope and promise in the present life (Titus i, 2); that this immortality is not a present possession (Mark x, 30), and is to be realized by the assumption of a spiritual body at the resurrection of regenerate men from the dead (Luke xx, 35, 36), an event synchronous with the second coming of Christ (1 Cor. xv, 51, 52). Divine testimony, no less than experience, they say, declares unequivocally that man has the same natural life as all other animals (Eccles. iii, 19), and only those who by faith and obedience are united to Christ have the promise of immortality. The Calvinistic doctrine of eternal misery is untenable, the punishment of sin being death or everlasting destruction, to be inflicted subsequent to a judgment after the Lord returns (2 Thess. i, 9, 10). The dogma of Universalism, the only alternative to endless torment if the soul must live forever, is also, they maintain, unfounded, since the punishment of sin (death) is said to be everlasting, like the life which is the reward of the righteous (Matt. xxv, 46). The Conditional Immortality Mission began in Great Britain in 1878. It has an organ *The Bible Standard,* published monthly by the secretary. Churches have been established in the United States.

CONDITIONAL LIMITATION. (1) A condition providing for the determination of an interest in land upon the happening of a particular contingency. It is a present interest only, lasting until terminated by the happening of the contingency, and is synonymous with a limited or qualified fee, such as a grant of an estate in land so long as the grantee shall remain unmarried or while any of his children are minors. At common law a contingent interest formerly remained in the grantor of such an estate, and upon the happening of the contingency the property reverted to the grantor or his heirs. This rule was abolished in England by statute late in the 13th century, thus making such an estate an absolute fee, but in many States of this country it has been held that the old rule that the estate will revert to the grantor or his heirs remains in effect. However, the grantor of such an estate cannot legally alienate the contingent interest he may possess therein before the happening of the contingency which terminates the estate in the grantee. (2) A use or interest in land *in futuro* effective on the happening of a given contingency.

In this sense the term is synonymous with *shifting use* or *springing use.* For example, a conditional limitation is granted to D in the following clause of a deed: «Said land is granted unto A and his heirs to the use of B provided that, if C lives and reaches his majority, the land shall go to the use of D in fee simple.» Often the estate determines only upon breach of a condition, as where land is devised to A while he remains in a given city or State, and if he fails to do so, the property to vest in B unconditionally. Upon the happening of the prescribed contingency, the estate first limited comes at once to an end, and the subsequent estate arises. . . . A conditional limitation is therefore of a mixed nature, partaking both of a condition and of a limitation: of a condition because it defeats the estate previously limited; and of a limitation because, upon the happening of the contingency, the estate passes to the person having the next expectant interest, without entry or claim. 63 Am. Dec. 725 (at 727). This form of estate is common both in Great Britain and the United States.

CONDITIONED, Philosophy of the, or Philosophy of the Unconditioned. The name given by Sir William Hamilton to certain philosophical views first promulgated by him in an article contributed to the *Edinburgh Review,* in October 1829, forming a critique on Victor Cousin's philosophy, especially of his doctrine of an absolute cause. The Unconditioned is regarded by Sir William Hamilton as a genus including two species: the Infinite, or the unconditionally unlimited, and the Absolute, or the unconditionally limited; and the thesis which he maintains and expounds in the essay referred to, and which forms one of the leading doctrines of his philosophical system, is that the Unconditioned, as thus explained, is entirely unthinkable. In his own words, «the mind can conceive, and consequently can know only the limited, and the conditionally limited. . . . Conditional limitation is the fundamental law of the possibility of thought.» This he illustrates by stating that we can neither conceive an absolute whole, that is, a whole so great that we cannot conceive it also as a part of a still greater whole; nor an absolute part, that is, a part so small that we cannot conceive it as a relative whole, divisible into still smaller parts. And this he declares to hold good as to

space, time and degree. «The Conditioned,» he goes on to say, «is the mean between two extremes — two unconditionates, exclusive of each other, neither of which can be conceived as possible, but of which, on the principles of contradiction and excluded middle, one must be admitted as necessary.» The Unconditioned, on the other hand, being merely negations of the Conditioned in its opposite extremes, bound together by the aid of language and their common character of incomprehensibility, is not even a notion, either simple or positive. It presents no object to the thought, and can afford no real knowledge. From this, however, we are only to learn that our faculties are weak, and that hence we have no right to constitute our capacity of thought into the measure of existence. Although then we are unable to conceive anything above the relative and finite, it is quite competent to us to believe in the existence of something unconditioned beyond the sphere of all that is conceivable by us. This doctrine was adopted by Mansel, dean of Saint Paul's, and applied by him to determine the limits of religious thought. It was combated by John Stuart Mill. Consult Hamilton, 'Discussions on Philosophy and Literature' (1852); Mill, 'Examination of Sir William Hamilton's Philosophy' (1865); Mansel, 'Limits of Religious Thought' (3d ed., 1870).

CONDOM, kôn-dôn, town in southeast France, in the department of Gers, on the Baïse River, which is here crossed by two stone bridges, 25 miles northwest of Auch. It contains an ancient church, a Gothic edifice of the 16th century, and in the outskirts are a number of handsome villas. The manufactures are iron founding, saw milling, porcelain, woolen yarn, leather and brandy. It was formerly the capital of Pays-de-Condomois. Bossuet was appointed Bishop of Condom in 1669, but remained here only one year. Pop. 6,380.

CONDONATON, in law, a forgiveness of injury, such as to restore the person who has committed an offense to the same position which he or she held before it was committed. In an action on the ground of adultery it is a legal plea in defense. If the act is committed anew, the condonation is annulled and the old charges are reconsidered.

CONDOR, the popular name of the great vulture of the Andes, formed by a mispronunciation of the Indian name *kunter,* which, according to Humboldt, is derived from another word in the language of the Incas, signifying «to smell well.» This species (*Vultur gryphus,* Linn., or *Sarcoramphus gryphus*) belongs to the family (*Cathartidæ*) of diurnal rapacious birds, and which is distinguished by the following characters: The bill is elongated and straight at base; the upper mandible is covered to the middle by the cere; the nostrils are medial, approximate, oval, pervious and naked; the tongue is canaliculate, with serrated edges; the head is elongated, depressed and rugous; the tarsus rather slender; the lateral toes equal; the middle toe is much the longest, the inner free and the hind one shortest; the first primary is rather short, the third and fourth are longest.

The natural history of the condor was in a fair way to rival the ancient fables of griffins, basilisks and dragons or even of exceeding the roc of Sinbad the Sailor, in extravagant exaggeration, until Humboldt placed it upon the basis of truth. His careful measurements established the fact that the wonderfully gigantic condor is not generally larger than the lämmergeyer, or bearded vulture, of the Alps, which it closely resembles in various points of character. These birds prefer to dwell above all animal life, and at the extreme limit of even Alpine vegetation, inhaling an air too highly rarefied to be endured, unless by creatures expressly adapted thereto. From such immense elevations they soar upward until their great bulk diminishes to a scarcely perceptible speck, or is lost to sight. The condor is a carrion bird, and is quickly lured to the plains by the sight or scent of a carcass. To such a feast considerable numbers repair, and commence their banquet by first plucking out the eyes, and then tearing away the tongue of the animal; next to these the bowels are eagerly sought for, and devoured with that gluttony which distinguishes the whole vulture tribe. Tschudi mentions one in captivity which ate 18 pounds of meat in a single day and had its usual appetite the day following. The appetite of these birds seems to be limited only by the quantity of food that can be gorged into their stomachs; and when thus overloaded they appear sluggish, oppressed and unable to raise themselves into the air. The Indians profit by this condition to revenge themselves for the robberies which they commit upon their flocks, and, watching while they eat until flight has become exceedingly difficult, attack and secure them by nooses, or knock them down with poles before they can get out of the way. If the condor, thus loaded, succeeds in rising a short distance from the ground, he makes a violent effort, kicking his feet toward his throat, and relieves himself by vomiting, when he soon ascends out of reach. Many, however, are surprised, and are captured or killed before they are able to ascend. But the condor does not exclusively feed upon dead or putrefying flesh; he attacks and destroys deer, vicuñas and other medium-sized or small quadrupeds; and when pinched by hunger a pair of these birds will attack a bullock, and by repeated wounds with their beaks and claws harass him until, from fatigue, he thrusts out his tongue, which they immediately seize and tear from his head; they also pluck out the eyes of the poor beast, which, if not speedily rescued, soon falls a prey to their voracity. It is said to be very common to see the cattle of the Indians on the Andes suffering from the severe wounds inflicted by these rapacious birds. It does not appear that they have ever attacked man. When Humboldt, accompanied by Bonpland, was collecting plants near the limits of perpetual snow, they were daily in company with several condors, which would suffer themselves to be quite closely approached without exhibiting signs of alarm and never showed any disposition to act offensively. The nesting-time of the condor varies with the latitude and the place selected for the nest is usually some inaccessible ledge of rock. It lays two white eggs from three and a half to four inches long, which are hatched in about seven weeks. The development of the young birds is very slow, since they are not able to fly until they are a year old, and they have to remain with the parent

birds for a year or two longer. They are occasionally seen even on the shores of the southern ocean, in the cold and temperate regions of Chile, where the Andes so closely approach the shores of the Pacific. Their sojourn, however, in such situations is but for a short time, as they seem to require a much cooler and more highly rarefied air and prefer lofty solitudes from 10,000 to 15,000 feet above the level of the sea. When they descend to the plains they alight on the ground rather than upon trees or other projections, as the straightness of their toes renders the first-mentioned situation most eligible. Humboldt saw the condor only in New Granada, Ecuador and Peru, but was informed that it follows the chain of the Andes from the equator to the seventh degree of north latitude into the province of Antioquia. There is now no doubt that it ranges from 9 or 10 degrees north of the equator to the Straits of Magellan. The king vulture (*S. papa*) is another bird of the same genus.

The head of the male condor is furnished with a sort of cartilaginous crest, of an oblong figure, wrinkled and quite slender, resting upon the forehead and hinder part of the beak for about a fourth of its length; at the base of the bill it is free. The female is destitute of this crest. The skin of the head in the male forms folds behind the eye, which descend toward the neck and terminate in a flabby, dilatable or erectile membrane. The structure of the crest is altogether peculiar, bearing very little resemblance to the cock's comb or the wattles of a turkey. The auricular orifice is of considerable size, but concealed by folds of the temporal membrane. The eye, which is peculiarly elongated and farther distant from the beak than the eagle's, is of a purple hue and very brilliant. The neck is uniformly marked by parallel longitudinal wrinkles, though the membrane is not so flabby as that covering the throat, which appear to be caused by the frequent habit of drawing the neck downward to conceal or warm it within the collar or hood. The collar in both sexes is a fine silken down, forming a white band between the naked part of the neck and beginning of the true feathers and is rather more than two inches broad, not entirely surrounding the neck, but leaving a very narrow naked space in front. The rest of the surface, the back, wings and tail are of a slightly grayish-black, though sometimes they are brilliantly black; the feathers are triangular and placed over each other tile-wise. Humboldt never saw male condors with white backs, though descriptions of such have been given by Molina and others. The primaries are black; the secondaries in both sexes are exteriorly edged with white. The wing-coverts, however, offer the best distinction of the sexes, being grayish-black in the female, while in the male their tips, and even half of the shafts, are white, so that his wings are ornamented with beautiful white spots. The tail is blackish, wedge-shaped, rather short and contains 12 feathers. The feet are very robust and of an ashen blue color marked with white wrinkles. The claws are blackish, very long and but slightly hooked. The four toes are united by an obvious but delicate membrane; the fourth is the smallest and has the most crooked claw. The largest male condor described by Humboldt was three feet three inches long from the tip of the beak to the tip of the tail; height, when perched, with the neck moderately extended, two feet eight inches; from the tip of one extended wing to the tip of the other, eight feet nine inches. Humboldt states that he never saw a condor which measured more than nine feet across the wings; but a specimen described by Dr. Shaw measured 14 feet. Notwithstanding, therefore, what is said by Humboldt of the general correspondence in size of the Alpine lämmergeyer and the condor of the Andes, we cannot avoid believing that a full-grown individual of the latter species would be much more than a match in every respect for any European species. The condor is peculiarly tenacious of life and has been observed, after having been hung for a considerable time by the neck in a noose, to rise and walk away quickly when taken down for dead, and to receive several pistol bullets in its body without appearing greatly injured. Its plumage defends its body to a considerable degree from the effects of shot. It is easily killed when shot, or struck sufficiently hard, about the head.

A very similar species is the California condor or vulture, which may be easily distinguished from the true condor, which it nearly equals in size, by the lack of the white neck-ruff and of the caruncle of the male. The California vulture formerly ranged on the Pacific coast into British Columbia, but its habitat is said to be shrinking and now reaches only to Monterey on the north. The species may be approaching extinction. Like the condor, in addition to feeding on carrion, it attacks and kills young or sick animals, particularly lambs and calves. The rough nest of sticks, in which two dirty-white eggs are laid, is built on the ground, rock ledges or stumps. Consult Adams, 'The Condor' (Vol. IX, California 1907); Beebe, 'Zoological Society Bulletin, No. 31' (New York 1908); Darwin, 'A Naturalist's Voyage' (London 1860); Lucas, 'Annual Report of the United States National Museum' (Washington 1891); Stejneger, 'Riverside Natural History' (Vol. IV, Boston 1885). For the California condor see Beebe, 'Zoological Society Bulletin, No. 32' (New York 1909) and Finley, 'The Condor' (Vols. VIII, IX, X, California 1906, 1907, 1908).

CONDORCANQUI, kŏn-dôr-kän-kē', **José Gabriel** ("Tupac Amaru"), Peruvian revolutionist: b. Tinta 1742; d. Cuzco, 18 May 1781. He is called "The Last of the Incas," and in 1771 took the name of Tupac Amaru. In 1780 he incited the Peruvian Indians to rebellion against Spain, professing a design of restoring the dynasty of Manco Capac. This rebellion was the most important in South American colonial history. For some time the contest raged with doubtful success; at length, however, the natives fell away from him and he was taken and executed. The cruelty of the Spaniards in this insurrection ultimately led to the independence of Peru.

CONDORCET, kôn'dŏr'sā', **Marie Jean Antoine Nicolas de Caritat, Marquis de,** French philosopher and mathematician: b. Ribemont, Picardy, 17 Sept. 1743; d. Clamat, 28 March 1794. He was educated by the Jesuits and showed a taste for mathematics at a very early age. Later he studied at the College of Navarre at Paris. At the age of 21 he pre-

sented to the Academy of Sciences an 'Essai sur le calcul intégral.' His 'Mémoir sur le problème des trois points' appeared in 1767. Both works were afterward united under the title of 'Essais d'analyse.' The merit of this work gained for him in 1769 the distinction of a seat in the Academy of Science. With astonishing facility and versatility Condorcet treated the most difficult problems in mathematics; but his genius inclined him rather to lay down beautiful formulas than to pursue them to useful applications. He became the friend of D'Alembert, Turgot and Voltaire, whose opinions influenced him greatly. His mind seized upon social problems, which he solved in a manner equally as brilliant as that of his famous contemporaries. In defense of free internal trade in corn, he wrote 'Lettre d'un laboureur de Picardie à M. N.' and 'Reflexions sur le commerce des blés' (1776). Against religious domination he wrote 'Lettre d'un theologien.' He also supported the American Revolution with great enthusiasm. His principal writings on this subject are 'Lettres d'un citoyen des États-Unis sur les affaires présentes' (1788); 'Lettres d'un bourgeois de Newhaven à un citoyen de Virginie' (1787); 'Reflexion sur l'esclavage des nègres' (1781). D'Alembert persuaded him to contribute to the 'Encyclopédie,' to which he responded by his facile and brilliant 'Eloges des academiciens de l'Académie Royale des Sciences morts depuis 1666 jusqu'en 1699' (1773). The ability which he manifested in this work gained for him the life secretaryship of the Academy of Sciences. In 1777 his 'Theory of Comets' gained the prize offered by the Academy of Berlin. The aversion of the minister Maurepas to Condorcet delayed his entrance into the French Academy till 1782. In 1785 appeared a distinguished mathematical treatise on the doctrine of probability. In the following year he married Sophie de Grouchy, a sister of Marshal Grouchy, a talented and beautiful woman. At about this time Condorcet became inspector-general of the mint, and at his residence at the Hôtel des Monnaies, there gathered the "Intellecti" of Paris. His 'Vie de Turgot' and 'Vie de Voltaire' appearing in 1786–87 became popular immediately. In point of style they are the best of his works.

When the Revolution finally came, Condorcet's eager and indefatigable pen rushed to the support of the democracy. He was chosen a member of the municipality of Paris (1790) and later a representative for Paris in the Legislative Assembly, of which he became a secretary. In this capacity he composed the addresses of that body to foreign powers and developed a strikingly comprehensive scheme of public instruction, which, after the turmoil of political strife had abated, was put into effective operation and still remains the basic structure of the French system of education. His program of organization had five steps: (1) primary schools; (2) secondary schools; (3) institutes; (4) lycées; (5) the Society of Arts and Sciences. After the flight of Louis XVI, Condorcet denounced royal authority as an anti-social institution and supported the National Convention. He took his seat in this body for Aisne and directed his first efforts toward the framing of a constitution, which was rejected. The trial of Louis XVI by the Convention was offensive to him, since he did not believe that body right in exercising judicial functions. He voted in favor of the removal of Louis and the infliction of any punishment except death. His critical and independent attitude toward the new constitution and toward the oppression of the Girondists and the terroristic principles of the party of the Mountain brought down on him the suspicion of the revolutionists. He was declared an outlaw. Refuge was found for him at the home of Madame Vernet, who did all in her power to prevent his escape and surrender to his enemies, even at the peril of her own life. Her words were remarkable for their lofty sympathy: "The Convention, Monsieur, may declare you outside of the law, it cannot place you outside of humanity." While at her house he wrote 'Esquisse d'un tableau historique des progrès de l'esprit humain,' by which he is best known. This work is a philosophical treatise on the history of man, tracing his evolution from a barbaric stage to the age of reason. He conceives that the chief errors in civilization have been brought about by the mismanagement by the clergy and monarchs. He outlines the future of man's progress on three lines: (1) The destruction of inequality between nations; (2) the destruction of inequality between classes; and (3) the unlimited improvement of individuals, mentally, morally and physically. Condorcet derives his theories from no spiritual postulates. His appeal is always to reason and to emotion aroused through reason. He finally quitted the house of Madame Vernet, and was captured in a half-famished condition at Clamat by a member of the revolutionary tribunal of that town. His captors threw him into prison, pending trial, and on the following morning he was found dead, either from apoplexy, exhaustion or poisoning.

Madame de Condorcet published a translation of Adam Smith's 'Theory of Moral Sentiments'; edited Condorcet's 'Éloges'; and, with Cabanis, published her husband's complete works (1801–04). Consult Arago, 'Biographie de Condorcet' (prefixed to the edition of 1847–49); Morley, 'Critical Miscellanies' (London 1893); Comte, 'Cours de philosophie positive' (Vol. IV); Cahen, L., 'Condorcet et la Révolution française' (Paris 1904); Guillois, A., 'La Marquise de Condorcet, sa famille, son salon et ses œuvres' (Paris 1897).

CONDOTTIERI, kŏn-dŏt-tyā'rē, class of mercenary adventurers in the 14th and 15th centuries, who commanded military bands, amounting to armies, on their own account and sold their services for temporary engagements to princes and states. The bands under command of the Condottieri were well armed and equipped. Their leaders had in many instances considerable military skill; but, as they took no interest in national contests, except to receive pecuniary advantages, the wars between them became a sort of bloodless contest, in which the only object of each party was to take as many prisoners as possible for the sake of the ransom. This singular system of warfare was put to an end by the more serious military operations of the French, who invaded Italy under Charles VIII. Though many Condottieri acquired much honor as well as emolument, one only attained to high rank and independent power; this was Francesco Sforza, origin-

ally a peasant, who in 1451 made himself Duke of Milan and transmitted that sovereignty to his descendants. Consult Semerau, 'Die Condottieri' (Jena 1909); Block, 'Die Condottieri: Studien über die sogenannten unblutigen Schlachten' (Berlin 1913).

CONDUCTING TISSUE, in botany, the system of vessels by which water and aliment is brought from one part of a plant to another.

CONDUCTION (from Latin *conductio,* bringing together). In botany, this is the technical name for the process whereby water and food-stuffs are transmitted from the roots of a plant to its trunk or stem and leaves. The paths by which these substances traverse the plant are well known. They enter the thin-walled root-hairs by osmosis, the food-salts being in a state of aqueous solution. From this point up, there is good evidence that the path of the water and the salts dissolved in it lies through the tracheids and the long tubular vessels of the fibro-vascular bundles, which are situated in the wood of the roots and stems of the Dicotyledons and Conifers, and form part of the leaf-veins. Only the young wood, however, takes part in this upward flow of sap. The motive force in the process has only recently been understood: the osmotic pressure of the juices of the root unquestionably plays a large part in the matter, but it is alone unable to make the sap rise to the tops of our larger trees. Furthermore, a cut branch with its end dipped in water will still show a flow of sap. Furthermore, if a living twig be divided under mercury, the wood-vessels will be found to contain some of the mercury on microscopical examination. As mercury will not enter a capillary tube of cellulose except under the action of a force, this result indicates that the pressure in the wood-vessels is less than that of the atmosphere. This could not be the case if root pressure were the only agent tending to produce the upward flow of sap; there must be accordingly some force producing a suction from above. This force is furnished by the osmotic attraction for water of the leaf-cells, whose contents are concentrated by evaporation and the consumption of their water in the photosynthesis of carbohydrates. This action is propagated from cell to cell until it reaches the vessels of the stem, each cell being, to put it loosely, sucked dry by its thirsty predecessor. This suction, producing a pressure in the vessels less than that of the atmosphere, causes the sap to give up part of its dissolved gases. This is probably one of the reasons why the vessels of a plant contain gases, which are, of course, in a state of rarefaction.

It has been shown that the path of the carbohydrates and other substances generated in the leaves is quite different from that of the water which comes up from the roots with its dissolved salts. For example, a girdled twig will keep green if its end is immersed in water, which shows that wood transmits water, but it will send down roots only from points above the injured region, because the portion of stem beneath the girdle has lost its power of obtaining food-material from the leaves and of growing thereby. The bark, therefore, and more specifically the bast layer of the bark, as it has been shown, is the path of the sap descending from the leaves. This layer contains the remarkable sieve-cells — elongated cells placed end to end in long chains, with the plates between adjacent cells in these chains perforated with numerous small holes. The mechanism of the transmission of food-stuffs appears to be diffusion.

In addition to the tracheids, vessels and sieve-tubes, we find another system of tubes in the vascular tissue of plants. This system bears the milky juice or *latex* of such plants as the rubber-tree, the dandelion and the milkweed. Though there is evidence that the latex exercises a nutritive function, the nature of this is not thoroughly known. Consult Timiriazeff, C. A., 'The Life of the Plant' (trans. by A. Cheremetieff, London 1912).

CONDUCTION OF HEAT. See HEAT.

CONDUIT, kŏn'dĭt, in a general sense a medium or means of conveying; anything serving as a channel for passage or transmission; in architecture, a long narrow passage between two walls or underground, for secret communication between various apartments, of which many are to be found in old buildings; also a canal of pipes for the conveyance of water, a sort of subterraneous or concealed aqueduct. The construction of conduits requires science and care. The ancient Romans excelled in them and formed the lower parts, whereon the water ran, with cement of such an excellent quality that it has become as hard as the stone itself which it was employed to join. There are conduits of Roman aqueducts still remaining, of from five to six feet in height and three feet in width. Conduits in modern times are generally pipes of wood, lead, iron, cement, reinforced concrete or pottery for conveying water from the main spring or reservoirs to the different houses and places where it is required.

CONDURANGO, kŏn-dŭ-răng'gō, or **CUNDURANGO,** (from the native Peruvian *cundur,* condor, and *ango,* vine), the bark of the Marsdenia Condurango or perhaps *Macroscepis,* a medium-sized twining plant of Ecuador and adjacent states. It is somewhat bitter; at one time it was much vaunted as a specific in the treatment of cancer.

CONDYLARTHRA, kŏn-dĭ-lär'thrą, a primitive order of fossil ungulates of the early part of the Tertiary Period, collateral ancestors of the later hoofed animals and connecting them with the primitive clawed animals, especially with the *Creodonta.* They were mostly of small size, five-toed, omnivorous, with bunodont teeth like those of the pigs, long tail, small brain and other primitive features. *Phenacodus,* of the Lower Eocene, of the size of a wolf, is the largest and best known. Remains of *Condylarthra* are found chiefly in North America, but also in Europe and in South America. They became extinct in the Middle Eocene.

CONDYLE (Fr. *condyle,* Lat. *condylus,* Gr. *kondulos,* knuckle), kŏn'dĭl, in anatomy, a protuberance on the end of a bone serving to form an articulation with another bone, and more especially applied to the prominence of the occipital bone for articulation with the spine; to the distal extremity of both the humerus and femur and to the proximal articular extremity of the lower jawbone of mammals.

CONDYLE, in ancient Greece, a lineal measure one-eighth of a foot.

CONE, Helen Gray, American poet: b. New York city, 8 March 1859. In 1899–1926 she was professor of English in the New York Normal College (now Hunter College). She is the author of 'Oberon and Puck: verses Grave and Gay' (1885); 'Baby Sweethearts' (1890); 'Soldiers of the Light' (1910); 'Chant of Love for England' (1915); 'The Coat Without a Seam' (1919). She assisted Jeannette L. Gilder in editing 'Pen Portraits of Literary Women' (1887). D. 31 Jan. 1934.

CONE, Orello, American educator and author: b. Lincleau, N. Y., 16 Nov. 1835; d. 23 June 1905. He was professor of biblical languages and literature in Saint Lawrence University, N. Y., 1865–80; president of Buchtel College, Ohio, 1880–96; and Richardson professor of biblical theology in Saint Lawrence University, 1900–05. He published 'Gospel-Criticism and Historical Christianity' (1891); 'The Gospel and Its Earliest Interpretations' (1893); 'Paul, the Man, the Missionary, and the Teacher' (1898); edited 'Epistles to the Hebrews, Colossians, Ephesians, Philemon, etc.' (1901); 'Rich and Poor in the New Testament' (1902).

CONE, Spencer Houghton, American clergyman: b. Princeton, N. J., 30 April 1785; d. 28 Aug. 1855. After a varied career as school teacher, actor, journalist and government clerk, he joined the Baptist Church in 1813 and began to preach. He was chaplain of the House of Representatives, 1815–16; pastor at Alexandria, Va., for seven years; of the Oliver Street Church, New York, for 18 years, and of the Broome Street Baptist Church in the same place from 1841 until his death. He was president of the American and Foreign Bible Society, 1837–50, and of the American Bible Union from its formation until he died. For many years he was one of the most popular and influential clergymen of his denomination in the United States. There is a 'Memoir' of him by his son, Spencer Wallace Cone (1819–88).

CONE. (1) *In geometry,* the solid figure traced out when a right-angled triangle is made to revolve round one of the sides that contain the right angle; this is more strictly a right circular cone. A more comprehensive definition may be given as follows: Let a straight line be held fixed at one point and let any other point of the line be made to describe any closed curve which does not cut itself; the solid figure traced out is a cone. The moving line is known as a generating line or generator of the cone. When the axis of the cone, that is, the line joining the fixed point to the centre of symmetry of the closed curve, is perpendicular to the plane of the base, the cone is right; and when in addition the curve which the second point describes is a circle, the cone is a right circular cone. Cones whose axis are inclined to their bases at any angle other than a right angle are known as oblique cones. If a cone be cut in two by a plane parallel to the base, the lower portion is called a frustum or a truncated cone. The geometry of the cone is important on account of the curves called conic sections, which are obtained by cutting a right circular cone by planes in various directions. The cubic content of a cone is one-third of that of a cylinder on the same base and of the same altitude. The cubical content of the cone is therefore found by multiplying the area of the base by the altitude and taking one-third of the product. The area of the slant or curved surface of a right circular cone is obviously equal to that of a sector of a circle of radius equal to the slant height, an arc equal to the circumference of the base. It is therefore obtained by multiplying the slant height by the circumference of the base and taking one-half of the product.

(2) *In botany,* a dry compound fruit, consisting of many open scales, each with two seeds at the base, as in the conifers; a strobilus.

(3) *In geology,* the heap or mountain of ash, cinders and lava piled up around a volcanic vent. Small cones on the flanks of larger ones are called parasitic. The term cone is also applied to the mound of silicious sinter (q.v.) built up around a geyser. See GEYSERS; MOUNTAINS; VOLCANO; and the section on *Volcanism* in the article on GEOLOGY.

CONE-NOSE. A true bug (*Conorhinus sanguisugus*) of the family *Reduviidæ,* related to the bedbugs and having similar habits in the South; it is nearly an inch long and black, blotched with red. In 1898 much excitement was occasioned in the North by newspaper accounts of attacks by "kissing-bugs," which were two related species, *Opisocœtus personatus* and *Melanolestes picipes,* the former frequently found in dirty houses feeding upon cockroaches, bedbugs, etc., and breeding in dusty corners. The bite is painful, but not poisonous.

CONE-SHELLS, or **CONIDÆ,** a family of ctenobranchiate *Gastropoda,* so called on account of their form. All the cones have a similar external outline; the aperture is long and narrow, the head of the living animal is more or less lengthened, the proboscis elongated, the foot is splay and abruptly cut off in front, the tentacles are rather widely separate and the eyes are placed on these organs. All of the species are carnivorous. Several hundred species have been described, about one-fifth of them from tropical American waters. Owing to their beauty and variety the cones are much sought by collectors, who pay extravagant prices for the rarer forms. The textile cone-shells (*Conus textilis*), brought from Mauritius, a handsome species four or five inches in length, are marked with narrow, angular lines of dark brown, variegated with dashes of yellow and irregular white spots. They haunt the fissures and holes in rocks and warmer pools in coral reefs. They all take a moderate range of depth, varying from 1 to 40 fathoms.

CONEPATL, or **CONEPATE,** kō'nĕ-pāt, the name given in Mexico to *Conepatus,* the large white-backed skunk of that region. See SKUNK.

CONES, Pyrometric, or **SEGER CONES,** instruments for measuring heat, consisting of three-sided pyramids about two and a half inches high and one-half inch base. They are composed of fusible substances and are graded so that they melt, each at its own temperature. The cones were invented by Dr. Hermann Seger, of Berlin, for use in pottery kilns and have since been largely adopted. An earlier method of heat measurement was the

fusible alloys invented by Prinsep. Alloys of silver, gold and platinum were so calibrated that they would, as to melting-point, cover the whole range between the two extremes of fusion of the metals. Many objections to these were found in practice, notably the expense and liability to loss. The Seger cones perform the same service and are very inexpensive. The cones range in numbers from 1 to 36 and back from .—1 to .—22. In practice two or three cones, approximating the required temperature, are set upright in the kiln upon a morsel of soft clay. The softer of them will, as the temperature reaches the proper point, bend over and melt, to be followed in regular order by the successive higher numbers. They can be easily seen through the hole left in the kiln wall for the inspection of trials.

CONESSI-BARK, the bark of *Holarrhena anti-dysenterica,* of the family *Apocynaceæ,* a plant of India, used as a tonic, a febrifuge and an astringent in diarrhœa. The plant is a shrub with opposite leaves and terminal cymes of flowers.

CONESTOGA, kŏn-ĕs-tō'gą, or **CONESTOGAS,** a tribe of Indians belonging to the Iroquois linguistic stock, and formerly living on the lower course of the Susquehanna and at the head of Chesapeake Bay. At the time of the settlement of Virginia (1607) the Conestoga were at war with the Mohawks, whom they had almost exterminated. Later they became a source of serious trouble to the white settlers. With the Dutch and Swedes they were more friendly than with the English. By 1675 the tribe was holding land on the eastern bank of the Potomac River in Maryland. Giving way before the Iroquois they retreated southward, committing depredations upon the white settlements. Some of the refugees of the tribe escaped to North Carolina; others after submission to the Iroquois returned to the Susquehanna. In 1701 the Conestoga made a treaty with William Penn.

CONEY, CONY (Lat. *cuniculus*; M. E. *cony, cunig,* rabbit). The word is believed to be of Hispanic origin and to have been borrowed into Latin. The name was formerly given in England to the rabbit. In the western United States, the name is applied to a distant relative, the pika (q.v.), although this creature has little resemblance to the rabbit. The term as found in Scripture is a translation of the Hebrew *shaphen,* the local name for the Syrian species of hyrax, or daman. The word Coney enters into a number of family and local names, as for example, Cunningham (Conyngham), Coney, Coningsby, Conington and Conythorp. The fur of conies or rabbits once much used in England, was called cony. The word also has the signification of a simpleton, dupe, gull. In the 17th century in England the den of thieves, cheats and swindlers was known as their warren, and their victims as conies, which, in this case, has the sense of young, inexperienced rabbits. This is the origin of the term simpleton as attached to the rabbit. See HYRAX.

CONEY ISLAND, New York city, small island in the borough of Brooklyn, about 10 miles southeast of the borough of Manhattan. It is about five miles in length and from half to three-quarters of a mile in width; separated from the mainland by Coney Island Creek, a narrow tidal inlet, Gravesend Bay and Sheepshead Bay. It is connected with the boroughs of Manhattan and Brooklyn by steam and electric railroads and steamboat lines. It is a noted day summer resort and has numerous bathing houses, hotels, concert and other amusement halls, carousels, pavilions, electric lights and fine boulevards connecting it with Prospect Park, Brooklyn. Coney Island is divided into four sections: Sea Gate, the home station of the Atlantic Yacht Club; West Brighton; Brighton Beach and Manhattan Beach. There is a lighthouse at Sea Gate and many summer cottages, besides the Atlantic Yacht Club House. Sea Beach is the site of several charitable sanatoria and is a popular pleasure resort. Brighton and Manhattan formerly had extensive hotels and were the preferred resorts for the wealthier class. Coney Island was one of the first landing-places of the Dutch, and for over 200 years was considered a worthless waste. In 1840 steamboats began making excursions there and for 25 years it was a popular resort. In 1875 steam railroads were built and since then the island has been the most popular resort in the immediate neighborhood of New York. In addition to boats, it is now reached by electric lines and buses and by a great boulevard. As many as 1,000,000 persons have visited the resort in a single day.

CONFARREATIO, kŏn-fâr-ē-ā'tyō, the most solemn of the three ceremonies of marriage used among the ancient Romans. The other forms of marriage were *coemptio* and *usus.* These last are the only ones mentioned by Cicero, which shows that confarreation had fallen into disuse before his time. The ceremony was performed by the *pontifex maximus,* or *flamen dialis.* A formula was pronounced in the presence of 10 witnesses, and the man and woman partook of cake of salted wheaten bread; part of which only they ate, the rest being thrown upon the sacrifice, which was a sheep. The cake was called *far,* or *panis farreus,* hence the term "confarreatio." By this form the woman was said to come into the possession of her husband by the sacred laws, and became a partner of all his substance and sacred rites, those of the penates as well as the lares. If the husband died intestate and without children, the wife inherited the whole property like a daughter; if there were children, she received with them an equal share. The offspring of this form of marriage were called *patrimi* or *matrimi;* and from them were chosen priests and priestesses, especially the *flamen dialis* and vestal virgins. In the reign of Tiberius, he wished for a priest of this pure lineage, but the ceremony had fallen into disuse, so that three patricians thus qualified could not be found. Confarreatio could only be dissolved by a form of divorce equally solemn, called *disfarreatio.* The custom of bride cake is a relic of confarreatio; until within 200 years it was made of wheat or barley, without fruit.

CONFECTIONERY (Lat. *conficere,* "to put together," "compound," "prepare"), a general term for any preparation with sugar as a base, used as a sweetmeat and containing nuts, fruits or other flavoring. In the United States confectionery is commonly called "candy," a

name which suggests etymologically conserved fruits or seeds; in England «boiled sweets» is the usual term, derived from the commonest method of preparation. Historically the earliest use of confectionery was to disguise the taste of unpleasant medicines, a method dating back to the primitive smearing with honey the rim of a cup holding a bitter draught, a practice common with Greek and Roman doctors. The medicinal use was long the commonest, fruit conserves being the first exception. In Italy, even in the Middle Ages, *confetti* were used in the mock battles of the carnival maskers. The true development of the manufacture of confectionery began in the 19th century, and in England, where the trade spread after the great exhibition of English dealers at the Exposition of 1851, to Germany and France. The latter country took the lead in the manufacture of elaborate bonbons and confitures and was especially superior in its chocolate candies. But the greatest growth of the business and especially the greatest increase in the variety of confections has been in the United States. The custom of making «confectionery» without the use of sugar was common in Mexico at the time of the Conquest. Different kinds of fruits were dried, mixed and compounded so as to make sweetmeats. The Indians soon learned the value of sugar in sweetening and preservation of these compounds; and «confectionery» in the modern sense was used in Mexico and Central America before it appeared in Europe where it was probably brought through the medium of Spain.

CONFECTIONERY TRADE. It is doubtful if there is any modern industry that has experienced more radical changes during the past hundred years than the trade of confectionery-making. Prior to the year 1851, the manufacture of «boiled sweets,» as candy was then called, was so largely an English specialty that the manufacturers of Great Britain might be said to have had almost entire control of the industry. In fact, it was not until the time of the great international exposition at London that the confectioners of other countries began to realize just how much their British brethren had achieved, but their unique display of candies and sweetmeats gave such an impetus to the trade that the effect was felt in every part of the civilized world. Germany imitated all its choicest products; France excelled, especially in the making of chocolate bonbons, and the candy-makers of the United States returned from the «big show» with ideas that soon made the importation of English sweets unnecessary.

In spite of the fact that England had long been the great candy-making country of the world, however, there had been confectioners in the United States long before the opening of the London exposition, and there are ample records in proof of the fact that they, too, had produced original creations that other nations were glad to copy. As early as 1816 there were no less than 20 confectioners in the city of Philadelphia, all of whom were engaged in the manufacture and sale of candies. Among these pioneers in the confectionery business one may record the names of Sebastian Henrion, who was succeeded by the firm of Henrion & Chauveau, in 1844, and Sebastian Chauveau, the first candy-maker to manufacture gum-drops, jujube paste and marshmallows in the United States. Another prominent manufacturer of the old time was Paul Lalas, who, in 1831, changed his business from that of candy-making to that of sugar-refining, while the list of Philadelphia confectionery-makers includes the names of George Miller, William N. Herring, S. S. Rennels and J. J. Richardson. Among the many old-time confectioners in the city of New York were Ridley & Company, a firm that was established as early as 1806; R. L. Stuart, James Thompson, John Stryker and Delmonico Brothers. In Boston, as early as 1816, Arnold Copenhagen, Lawrence Nichols and William Fenno were prominently identified with the candy industry, while Joseph Bouvey, Augustus M. Price and John L. Bridges were among the leading manufacturers and dealers in confectionery in Baltimore. Throughout the United States there were some other cities that could boast of candy-makers, but the records of those days are so meagre that but few of the names can be recalled.

In the beginning, of course, the art of candy manufacture was in a very crude state. Prior to 1845, it was almost invariably the rule that the manufacturers themselves sold at retail practically all the candy that they manufactured. As a rule this stock in trade was confined to such ordinary products as the old-fashioned stick candy, sugar plums and the ordinary molasses candy. Finer goods, or candies in fancy shapes, were almost exclusively imported and were sold at a much higher price than the crude candies of home manufacture. About 1825 the foreign manufacturers began to use a little machinery in their factories, but the actual introduction of machinery in the making of confectionery dates from about 1840. The first machine of this character to be brought to the United States was imported by Sebastian Chauveau of Philadelphia, in 1845. This was a revolving steam-pan. In 1846 Oliver R. Chase, who, with his brother, formed the firm of Chase & Company, invented a machine for the making of lozenges. For some years this firm had been engaged in making this once popular confection as a specialty, and it was to meet the constantly increasing demand for their product that this new invention was conceived and constructed to their model. In 1866, a further innovation in the lozenges manufacture was produced by Daniel G. Chase. This was a machine for printing on candies, and it was to this invention that the well-remembered conversation lozenges owed its existence.

Since that day the history of the confectionery trade has been a constant record of development. Year by year new improvements have been made and new and more perfect machinery has been invented, all of which have quickly been adapted to the manufacture of the various kinds of goods that the constantly widening demands of the business have required. While the actual manufacture of candy has extended until it has become one of the nation's greatest industries, it has created around it a number of dependent industries, each of which now represents a special business of no slight importance. Thus, for example, the making of confectioner's machinery is now a separate industry in which a

great amount of capital is invested, and the business of confectioner's supplies represents an annual product that is by no means to be despised.

There are other factors that have played an important part in this extension of the confectionery industry. The low prices of sugar and the other materials used in the making of confectionery have exerted an influence, the effect of which cannot be disregarded, while the introduction of new and improved machinery in all our candy factories has a tendency to reduce the cost of manufacture to such a degree that the American producers have been able to make the best goods at a cost so low as to bring them within the reach of all.

Much of the credit for this satisfactory condition of affairs is due to the labors of the members of the National Confectioners' Association of the United States. This organization, founded in 1884, which includes in its membership all the leading candy manufacturers of the country, has for its declared purpose, "to advance the standard of confectionery in all practicable ways, and absolutely to prevent hurtful adulterations; to promote the common business interests of its members, and to establish and maintain more intimate relations between them; to take united action upon all matters affecting the welfare of the trade at large."

Since this association has been in existence the results of its work have been clearly manifested in the securing of necessary legislation in the several States by means of which the manufacture or sale of all candies containing harmful ingredients or poisonous coloring matters has now been prohibited by law; by effectually stamping out all attempts at adulteration which were once so common among the makers of the cheaper grades of goods, and by the establishment in the mind of the consumer of a degree of confidence in the purity of the American product that is a strong argument for the purchase of such goods. As the result of this happy combination of circumstances we have the great American confectionery industry of to-day.

Candies may be divided roughly into hard and soft grades. The hard candy is made of sugar, glucose, flavoring and coloring, with sometimes additions of nuts, etc. Starch is a leading constituent of soft candies. The hard candies were the first to be made by machine, but gradually mechanism has been developed for making soft and fancy candies largely by machinery, and makers of high-priced, hand-made candies are kept busy devising new concoctions to keep ahead of the machine product. Cane-ground sugar is almost wholly employed, and for hard candy the proportion is usually 85 per cent sugar to 15 per cent glucose. Glucose being a pure product of Indian corn adds to the nutritive value of candy. The hard candy ingredients are mixed in copper kettles and cooked, more heat being required in summer than in winter to ensure a hard candy. When cooked it is poured on a slab and cold water run on. Marble is now seldom used for slabs, steel proving more satisfactory. The product is then kneaded and pulled on a hook until white. It is pulled by hand, the candy-maker wearing buckskin gloves; or it may be pulled by an ingenious machine with continuous cranks that imitate the motions of hand-pulling. When it is pulled white, it is cut into sticks, slabs or rolled into balls or other forms.

In a large candy factory the sugar, glucose, starch and other materials go to the top floor, where all operations are begun. Here are the steam-jacketed cooking kettles. If starch goods are being made, the cooking kettle used is directly over the "depositor" machine on the floor below, so that the mixture may go down by gravity. If hard candy is being made, the first kettle is right over the continuous cooker. If it is cream candy, the kettle is positioned to discharge to a cooler; when cooled the cream goes to a beater and is distributed in trucks. The centres or soft interiors go to a coating-machine, styled an "enrober," which supplies the familiar chocolate coating, and then to the coolers and packers. Traveling platforms are employed where gravity is not available. In the modern candy factory the formulas used are exact, everything is measured and weighed and no guesswork permitted, hence spoiled batches are rare.

Very numerous machines have been developed for performing the different processes and producing the desired varieties of confectionery. The number of machines required for a varied product was so great that an equipment became burdensome to the manufacturer. Therefore in recent years the machine manufacturers have bent their energies to reduce the number of machines required in a candy factory, and to simplify the processes, as well as to eliminate hand labor. One of the most interesting of these machines is the Mogul, which is really a combination of machines grouped in one. It takes a pile of starch trays, filled with candy and starch, hardened to the desired degree, picks the bottom tray from under a pile, carries it to a screen and turns it upside down, delivering the contents to the screen, restores the tray to position, passes it under a cascade of starch, levels off the starch and brushes it up neatly, prints all the starch molds in a tray at one operation and adds the exact amount of candy desired, then delivers the tray to a truck to go to the drying-room. Surplus candy dosed with starch is automatically cleaned by the machine for reuse.

The work of this Mogul machine is done in some factories by three machines, the Simplex starch buck, which cleans molded candy, refills and levels the trays; the Springfield printer, which prints the molds in the leveled trays of starch; the Springfield depositor, which deposits candy into molds. The enrobing machine, which chocolate-coats centres, is often provided with an attachment for making extra heavy bottoms, as for chocolate drops. The enrober has an ingenious decorating attachment. The centre candy is rotated under a fine stream of colored chocolate or other tinted liquid and may thus be decorated with an endless variety of patterns. An enrober will dip 6,000 cream bars in a day.

The old-fashioned vacuum pan is disappearing from candy factories and the continuous cooker taking its place; it uses more glucose and less sugar and gives a glossy product. The disc reducer and disc refiner for chocolates displace a whole line of old machinery. The reducer grinds the chocolate, mixes in the granulated sugar, butter, etc., and the mixture

is pumped as a fluid to a revolving disc operating between two stationary corrugated discs, where the mixture is refined in a few seconds. The candy-maker also uses gooseberry or ball machines for round candies; specially designed packing tables, wrapping machines for doing up the candies in dainty individual wrappers, syrup coolers, cream beaters and a variety of minor conveniences.

Statistics.— Few industries have grown as rapidly and extensively as the confectionery industry of the United States. In the 30 years from 1889 to 1919 the number of wage earners in the business increased from 21,724 to 76,493; capital invested increased from $23,327,000 to $219,635,000; wages paid arose from $7,783,000 to $54,461,000; the value of products arose from $55,997,000 to $447,726,000; the cost of materials from $31,117,000 to $252,434,000 and the value added by manufacture from $24,880,000 to $195,292,000. Between 1889 and 1919 there was a wide variation in the number of industries engaged in the confectionery business. The number reporting in the first mentioned year was 2,921; by 1899 the number had dropped to 962, by 1909 it had risen to 1,944 and when the Fourteenth Census was taken, the number of concerns reporting was 3,149. New York with 414 establishments turning out products valued at $37,068,000 was the leading State in the industry in the year 1919, Illinois came second with 237 establishments and products valued at $26,085,000, while Massachusetts, with an output valued at $25.682.000 from 130 factories was third. The statistics for 1937, as reported by the United States Bureau of the Census, showed 1,226 establishments engaged in the manufacture of confectionery in that year. These employed 53,722 wage earners who received $43,440,677 in wages. The output for the year was valued at $305,839,262; materials cost $182,781,196 and the value added by manufacture was $123,058,066. The output of chocolates alone totaled 297,311,100 pounds, valued at $102,346,113. Bar goods amounted to over 400,000,000 pounds, valued at $71,560,300. There were also manufactured over 175,000,000 pounds of hard candy, valued at $29,614,300; 83,410,000 pounds of caramels and chewing candy valued at $11,715,600; 73,476,000 pounds of worked gum valued at $8,111,400; besides marshmallows, lozenges, other confectionery and salted nuts. The Bureau of the Census lists chewing gum as a separate industry, with a value for its products in 1937 of $58,715,400. (See CHEWING GUM.)

The chocolate and cocoa industry lives mainly on supplying the confectionery trade with materials, producing $102,346,113 of goods in 1937. Consult Jordan, S., 'Confectionery Standards' (New York 1933); Skeats, A. C. E., 'Commercial Confectionery' (London 1937); O'Neil, F., 'Candy Tricks and Treasures' (Greenfield, Mass. 1935).

CONFEDERACY, Daughters of the. See UNITED DAUGHTERS OF THE CONFEDERACY.

CONFEDERATE STATES OF AMERICA. The name adopted by the Southern States which seceded from the Union and formed a government at Montgomery, Ala., 9 Feb. 1861, comprising South Carolina, Georgia, Florida, Alabama, Mississippi and Louisiana, with Jefferson Davis of Mississippi President and Alexander H. Stephens of Georgia Vice-President. Texas, Arkansas, Tennessee, North Carolina and Virginia afterward joined, and Missouri and Kentucky became disputed territory, the Federal Congress and the Confederate each receiving and welcoming delegations claiming to represent those States.

The act of secession was passed by each State in full confidence that the legal right peaceably to secede was assured by the Constitution. And if the interpretation of any ambiguous provisions or expressions in any contract is to be governed by the joint intent of the parties at the time of making it, this right to secede must be conceded by all impartial historians.

Goldwin Smith, the English historian, has written: "Few who have looked into the history can doubt that the Union originally was, and was generally taken by the parties to it to be, a compact, dissoluble, perhaps most of them would have said, at pleasure; certainly on breach of the articles of union."

Henry Cabot Lodge of Massachusetts has written: "It is safe to say that there was not a man in the country, from Washington and Hamilton on the one side, to George Clinton and George Mason on the other, who regarded the new system as anything but an experiment entered upon by the States, and from which each and every State had the right peaceably to withdraw, a right which was very likely to be exercised."

In 1803, at the purchase from France of the Louisiana territory, and again in 1812, at the declaration of war with Great Britain, influential and leading public men in New England not only asserted the right of secession, but urged its exercise, in the celebrated Hartford Convention (q.v.) in 1814–15.

Nowhere, however, until 1860, was the issue actually made. Had it been made in the earlier days, it would doubtless have been accomplished peacefully. But in all human affairs, political, social, moral or commercial, there are silently but forever at work forces which make for the survival of the fittest, and the passing away of the unfit; and these forces, when at last a crisis has been reached, declare themselves, and operate with a volcanic power, against which the barriers of no constitution can prevail.

Within the lifetime of a generation the moral sense of a majority of the civilized world had grown to condemn the institution of slavery; and the invention of steam-power, railroads and telegraphs had begun to knit communities into nations, to their great commercial advantage. The prejudices against slavery gave rise to issues between the sections of the country, which became inflamed by events — such as the raid of John Brown—until certain States were wrought up to the point of seceding.

But now — born, not legitimately of the Constitution, nor of consent between the States (which could never have generated anything more cohesive than a rope of sand), but of inexorable laws of nature — there stood a giant in the path. Perhaps, indeed, it was of origin unsanctioned by legal form. But it was born of proximity and geographical dependency, and it was nourished by the prosperous tide of commerce already beginning to transform the entire world. It already felt itself the natural

heir to the vast and rich territory within its grasp. There it stood in the way of peaceable secession — a young nation, which denied the right of secession and stigmatized it as rebellion.

In vain did President Davis plead his constitutional rights, in a message to his Congress: «We protest solemnly, in the face of mankind, that we desire peace at any sacrifice, save that of honor. In independence, we seek no conquest, no aggrandizement, no concessions of any kind, from the States with which we have lately been confederated. All we ask is to be let alone; that those who never held power over us shall not now attempt our subjugation by arms.»

It needed now but a first blow to precipitate a war to the death. Concerning first blows, Richard Cobden once said: «From the moment the first shot is fired, or the first blow is struck, in a dispute, then farewell to all reason and argument: you might as well attempt to reason with mad dogs as with men when they have begun to spill each other's blood in mortal combat.»

The first blow came speedily, but by deliberate intent of neither party. In Charleston a status quo had been agreed upon by both sides, to permit negotiations. On 25 Dec. 1860, Maj. Robert Anderson seized Fort Sumter. He did so by night, without orders, and contrary to his instructions, abandoning Fort Moultrie and disabling its guns. President Buchanan was about to order him to return to Fort Moultrie; but before the order could be issued the act was approved so enthusiastically by Northern politicians that he did not dare to reverse it. Holding Fort Sumter, he was then constrained to dispatch an armed force to provision and supply it. Thus the Civil War was begun, the Confederates not waiting for the arrival of the armed force, but making their attack.

This breaking out of hostilities brought into the Confederacy the Border States, not so vitally interested in the subject of slavery, but with every tradition and instinct keenly alert to their legal rights under the original Constitution.

This was the real issue of the War, and not slavery, as is often loosely asserted. It is attested, not only by the titles «Union» and «Rebel,» universally applied to the two armies by the North, but by the passionate claim of the Confederates that their struggle was for that liberty of self-government so dear for ages to the Anglo-Saxon race. And at the Fort Monroe conference in February 1865 between President Lincoln and Vice-President Stephens, the South's surrender of her claim to integrity of the Union was the one point upon which Lincoln insisted, and the one which Stephens could not yield, although utter destruction awaited him scarcely 60 days off. It is further shown in the desperate character of the struggle upon both sides, involving, with equal ardor, individuals and communities of most diverse degrees of interest in the question of slavery.

The combatants were very unequally matched, and as each side was in deadly earnest, the final outcome of the contest was inevitable from its beginning. On the Union side was a population of over 20,000,000, with an army, a navy, a treasury, a highly developed system of transportation by land and sea, as well as of manufactures, of commerce and of credit. On the Confederate side was a much scattered population, almost entirely agricultural, of from 8,000,000 to 10,000,000, comparatively destitute of all those elements of military strength. Even their agriculture was so little devoted to food products that actual starvation of men and horses in their armies finally hastened the inevitable end.

In this population there were included about 4,000,000 slaves. It was believed by many at the North that if their freedom was proclaimed by President Lincoln, as a war measure, while their masters were absent in the field, they would rise in insurrection, or at least desert their labor in mass. The experiment, however, being tried, proved a failure. The slaves generally remained faithful everywhere, except in the sections overrun by the enemy. During the four years of the war there were actually mustered into the Union army 2,898,304 men. The Confederate numbers cannot be accurately known, but the total white male population between the ages of 18 and 45 was, by the census of 1860, 984,475. In 1864 the ages of military service were extended to include all between 17 and 50, an act which was described by General Grant as «robbing the cradle and the grave.» Nearly 2,000 battles and skirmishes were fought, and in them the number of killed and wounded on the Union side is officially given as 389,345. The numbers on the Confederate side are not accurately known, no complete records existing, but they are estimated at about 300,000.

Of lives lost in the war from battle, wounds and disease, the official records of the Union army report 316,516. The lives lost in the Confederate army could not have been less than 250,000.

The Confederates appreciated the odds against them, but with firm conviction of the righteousness of their cause they trusted to be able by fortitude and endurance to wear out and discourage their adversaries. The fighting was often very desperate as shown by the casualties upon both sides, which frequently exceeded the casualties of the severest battles of Europe. Upon three occasions, some historians have imagined, the Confederates were within reach of very important results.

At Bull Run, the first battle of the war, the Federals were completely routed and Washington might have been captured, it is supposed, had the victory been followed up. Gettysburg is considered by many to have been the crisis of the war, a desperate attack by the Confederates being repulsed. But there is strong evidence that the greatest period of discouragement on the Union side followed the battle of Cold Harbor, 3 June 1864. It was, however, of brief duration and of no effect. Successes elsewhere soon followed and made it apparent that the Confederate resources were approaching exhaustion.

There are notable parallels between the war for the Union and the war between Great Britain and the Boers, in the issues involved and in the course of their events. Like the Confederates, the whole of the Boer population considered themselves fighting for personal liberty as against subjection to a foreign power. Like the Confederates, the Boers fought practically without pay; and although they were

inferior in numbers their important engagements were generally victories; or, if not victories, were drawn battles. And as the end came to the Confederates, so it came to the Boers only with their utter exhaustion — through their being worn out, rather than defeated in battle.

But a great contrast is to be found in the treatment of the two peoples after their defeat. That of the Boer was liberal and generous, fully in accord with the civilization of the day. To parallel the treatment of the South every effort must have been made to put the political control of the country into the hands of the Kaffirs. Of course the efforts to give the negro political control over the Anglo-Saxon at the South were foredoomed to failure. They prolonged ill-feeling for 10 years; but subsequent events, notably the Spanish War, at last inaugurated a new era in which few traces of it yet linger. And it is due to history to record that it is unlikely that any such effort would ever have been made, but for the assassination of Lincoln. Although for this unspeakable crime and folly the South was in no way responsible, it brought upon her a whirlwind of resentment and at the same time it removed a President who, there is evidence to show, had already risen to the height of his great opportunity as a statesman, and was now planning terms of liberality upon which to reconstruct the Southern States.

Within the few days that intervened between the surrender at Appomattox and the assassination of Lincoln, one in his close confidence prophesied that his plans of reconstruction would «win over the South's good will and affection, and astonish the world.» And in giving his plans effect, no one can doubt that he would have had the cordial as well as powerful aid of General Grant, who had already set the example of magnanimity, and won the gratitude of Lee's army by the generosity of his terms of surrender.

History records no crime greater than that of the assassin, who cheated the civilization and humanity of the world of the great example which Lincoln would have set to all nations, and who sowed bitterness and ill-will between the sections, bringing poverty and distress to the South, to the North the mortifying failure of its political experiment and to the negro only an injury. But in connection with the negro question, as it confronts us to-day, it may be remarked that the problem of the races can be safely committed to time and to the racial instincts implanted by the Creator.

The Constitution which was adopted by the six States in Montgomery, February 1861, and in turn accepted by the others, was modeled closely after that of the United States. It forbade the slave-trade, or the importation of slaves from any foreign country other than the slaveholding States and Territories of the United States. It forbade «bounties» or «trusts» and provided a «tariff for revenue.» It allowed the President to veto any part of a bill and approve the remainder, giving his reasons for such action; and fixed his term of office at six years and made him ineligible for a second term.

The internal history of the Confederate States during the Civil War furnished a most instructive lesson as to the weakness of the bond by which they had associated themselves. Already, before the close of the war, it had proved itself but little better than the federation of the colonies for the Revolutionary War. The last message of President Davis to the Confederate Congress, and the answering report upon the message by a committee of the Senate, contained much crimination and recrimination, and revealed an utter loss of confidence between the executive and the legislative branches, fatally paralyzing all action, and impossible to be healed. In a letter to the Secretary of War, on 5 March 1865, Judge John A. Campbell, assistant secretary, wrote: «The political condition is not more favorable. Georgia is in a state that may properly be called insurrectionary against the Confederate authorities. Her public men of greatest influence have cast reproach upon the laws of the Confederacy and the Confederate authorities, and have made the execution of the laws nearly impossible.» In several of the other States there were also very serious issues between State and Confederate authorities.

In view of these facts, and of the history of all confederations of many small countries, it may now be clearly seen that the prize for which the South contended so strenuously would have proved but a calamity had she won it. There would have been in the country a condition of unstable equilibrium, with many centres of disturbance, which would surely have involved further division and probably further wars. To-day her people are citizens of a nation second to none in military renown or commercial strength, or in its power and influence for peace and civilization among the peoples of the earth. Were the right peaceably to secede, for which the South cheerfully endured all the bitterness of war, now tendered her as a free gift, every State would unanimously reject it as a curse.

Few generations of modern times have confronted sterner problems than did the men of the South in 1861. In the natural world, whenever the climate has changed, the fauna and flora have had to change to conform to new conditions. This is the law of evolution, the one great truth of which mankind may feel assured «Eternal Justice» will alone prevail through «Conformation to Environment.» And the natural resistance to change by all interests in possession makes evolution mean war to the death of the least fit and the survival of the fittest.

Had the South been quick to apprehend these truths, then being first published to the world by Darwin, she might have accepted compensation for her property in slaves and surrendered her constitutional right to secede. Had she done so, over 500,000 lives and $10,000,000,000 of property would have been saved.

But the Anglo-Saxon is not a ready barterer of what he deems his «rights.» Nor would any nation thus founded upon «consent» have commanded confidence, or even inspired the national pride and loyalty which form the greatest treasures of a people. The conflict, with all its death and destruction, its sorrows and its sufferings, was but the necessary baptism of this nation, legitimating its disputed birth by a verdict in the great high court of war, rendered in accordance with the laws of evolution, beyond which there is no appeal.

But while the generation which so lavishly poured forth blood and treasure may rightfully cherish to the last an ardent affection for its «Lost Cause,» with its leaders and its heroes, not only its own children, but all succeeding generations, will enjoy great and enduring benefits and blessings, the very fruit of the desperation of its struggle and of the utterness of its defeat.

And in its influence upon national character, and upon the standing of this nation among other nations, it is no small matter to have made the record for valor and devotion to principle which the South has set; or to have produced such leaders and types as Lee and Jackson and their colleagues.

Briefly it may be said that the rise and fall of the Confederate States of America constitute the most important feature of modern history, marking the sudden birth of a great nation. Such a nation could never have been founded in peaceful debate. The world may eventually reach a stage of development where such an event may be possible, but it had not done so in 1860. Previous to that date there was no assurance of stability to the nation. Since 1865 no convulsion could shake it. Succeeding years only demonstrate to the inhabitants of every section the increasing advantages of living in an undivided and an indivisible country. See UNITED STATES — THE CONFEDERACY.

EDWARD PORTER ALEXANDER.

CONFEDERATE STATES OF AMERICA, Recognition of the. The failure of the Confederate government to secure recognition was not due to lack of confident or persevering effort or deficiency in number of agents sent abroad. Unsuccessful in its effort to negotiate a peaceful separation by a commission sent to Washington, and failing in a plan to form an alliance with Mexico, it continued to press for recognition at the chief courts of western Europe. At the beginning its hope of success was largely based upon the dependence of Europe on the supply of Southern cotton and no serious consideration was given to the possibility of a blockade such as that which became the determining factor in preventing independence. It continued to expect that the need of cotton would force recognition or intervention by England and France or by France and Spain, whose West Indian possessions she offered to guarantee in return for alliance. These hopes were temporarily raised by the *Trent* affair, by the earlier policy of the British government in failing to prevent the escape of Confederate cruisers built in English ports, by Lee's invasion of the North preceding the battle of Gettysburg, and by the later complications of France in Mexico which encouraged Napoleon to favor a counterpoise to the growing strength of the United States. They declined with the progress of events, but were revived by the prospects of an Anglo-American or a Franco-American war and by attempts to impress England and France with the belief that the United States was planning aggression against neighboring possessions or that the restoration of the Union would result in an aggressive war against England and France and finally feeling that European public opinion was opposed to slavery the Confederacy in its last death struggle offered emancipation for recognition and intervention.

Attempts to secure recognition of independence failed because of conditions over which the Confederate government had no control and could not fully appreciate. Recognition was prevented largely by the diplomacy of Seward, the proclamation of emancipation, the increasing success of Federal military operations, and the obstinate persistency of the Federal government in avoiding any official communication which might be interpreted as a recognition of the existence of even a *de facto* Confederate government. To this may be added the friendly attitude of the Russian government and the hesitation of the English government to join France in a policy which would have been resented by the American government as excessively unfriendly. Although during the war, the United States government, usually through military officers, from necessity communicated informally and unofficially with the agents of the Confederate authorities in regard to such questions as exchange of prisoners and terms of surrender, it persistently avoided any formal act which could have been interpreted as a recognition of the Confederate government. This is illustrated by the character of the Hampton Roads Conference. The Federal courts have always held that the Confederate States were «an unlawful assemblage without corporate power» and that the government of each separate indestructible State when it chose to act as a part of the Confederate States did not exist either *de jure* or *de facto*. The British proclamation of neutrality of 13 May 1861 (followed by similar declarations by France, Spain and other powers), which recognized the belligerent rights of the Confederacy on the ground that it was justified by the declaration of an effective blockade of the insurgent ports by the *de jure* government at Washington at the beginning of the war, was strenuously but unsuccessfully opposed by Seward who affirmed that the neutrality proclamation of the European powers would be liable to be construed as a recognition of independence and really created the belligerency of the Confederacy which had not exhibited a single privateer upon the ocean nor shown capacity

to maintain any kind of warfare except in its own harbor. This concession of belligerency was not withdrawn by England and France until June 1865 although Seward took steps early in 1862 to secure its revocation or revision. Charles Francis Adams took some consolation in observing that Great Britain by this act had released the United States from liability for the misdeeds of the Confederates toward her. The United States courts have repeatedly decided that a state of civil war, which entitled the Confederacy to recognition as a belligerent, did not exist until President Lincoln issued his proclamation of 16 Aug. 1861 (based on the act of Congress of 13 July).

In the face of reported danger of European recognition of Confederate independence Seward urging that the likelihood of success was the only ground for recognition frequently issued instructions or circulars defining the American position against such action or against any form of European mediation or intervention. Seward early notified England and other powers that the recognition of the «so-called Confederate States» would be regarded in the United States as intervention and war to create a hostile state within the national boundaries — and that it would result in the immediate suspension of diplomatic relations and would be resented on the principle of self-preservation. He objected to the reception of Confederate commissioners by other nations or the consideration of any proposals which might seem to recognize the Confederate States in any way except as a part of the United States. Although he continued to insist that the informal reception of Confederate emissaries by officials of foreign governments was improper and unfriendly to the United States and consistently governed his own conduct accordingly in cases of unofficial missions from other countries, he left untried the policy of retaliatory non-intercourse which he early proposed in his instructions to Adams. In the summer of 1861 he revoked the exequatur of a British consul at Charleston who with the authority of his government had conducted negotiations with the Richmond authorities in regard to the rights of neutrals; and he could not grant the right claimed to communicate with a *de facto* government such as the central authority at Richmond or the governors of separate States to provide for temporary security of persons or property of British subjects or to claim redress and reparation although Earl Russell declared that such communications did not imply any acknowledgment of the Confederacy as an independent state. With the knowledge that France and England, acting in concert on questions relating to the American Civil War, might try by combined pressure to prevent the United States from regulating its own internal affairs, he announced that he could not recognize any combination or understanding of the powers, and insisted upon dealing with each government separately. He also declined Napoleon's offer of mediation, the officiousness of which was rebuked by Congress. Seward's efforts to prevent recognition were greatly aided by the Russian government which refused the invitation of the French emperor in the autumn of 1862 to co-operate on some plan of intervention to stop the Civil War, and later sent its fleet to American waters to show friendship for the American Union just after the crisis of the middle of 1863 during which Napoleon, before the arrival of the news of Gettysburg and Vicksburg, had hoped to push the careful government of England into a policy of joint recognition and intervention.

Professor of Political Science, University of West Virginia.

CONFEDERATE VETERANS, The United, a federation of all organizations of survivors of the Civil War on the Southern side. This association was organized at New Orleans 10 June 1889. Its avowed purpose is strictly social, literary, historical and benevolent. Its constitution says that it "will endeavor to unite in a general federation all associations of Confederate veterans, soldiers and sailors now in existence or hereafter to be formed; to gather authentic data for an impartial history of the War between the States; to preserve relics or momentos of the same; to cherish the ties of friendship that should exist among men who have shared common dangers, common sufferings and privations; to care for the disabled and extend a helping hand to the needy; to protect the widows and the orphans, and to make and preserve a record of the resources of every member, and, as far as possible, of those of our comrades who have preceded us in eternity." State organizations were authorized, and were called divisions. Local organizations were termed camps. Of these there were about 1,200, organized into three departments: Army of Northern Virginia; Army of Tennessee and the Trans-Mississippi Department. The badge worn on the lapel of the coat is a miniature Confederate flag, square in form. The official organ, *The Confederate Veteran,* is published at Nashville, Tenn. The organization is rapidly decreasing in numbers.

CONFEDERATION, Articles of. See UNITED STATES — ARTICLES OF CONFEDERATION.

CONFEDERATION OF THE RHINE. A league of German princes which was formed, under the protection of Napoleon, in 1806. In the war of 1805, which turned out so unfortunately for Austria, several of the princes of the south of Germany allied themselves to France. The Peace of Pressburg (26 Dec. 1805) gave the first impulse to the entire dissolution of the German empire, by conferring crowns on the electors of Bavaria and Würtemberg, and on both, as well as on Baden, complete sovereignty, such as had been already exercised by the other great German states. Ultimately 16 German princes made a formal declaration of their separation from the Emperor and the Empire, in the act of confederation signed at Paris 12 July 1806, by the kings of Bavaria and Würtemberg, the elector arch-chancellor of the Empire, the Elector of Baden, the new Duke

of Clèves, and Berg (Joachim Murat), the Landgrave of Hesse-Darmstadt and other less important rulers. Other princes soon joined, and ultimately the confederacy extended over a space of 125,160 square miles, with 14,608,877 inhabitants; and the confederate forces were increased from the originally stipulated number of 63,000 to 119,180. After Napoleon's Russian campaign of 1812 the whole structure fell to pieces in 1813. Consult Rambaud, 'La domination française en Allemagne, 1804–11' (Paris 1876), and any good history of Germany.

CONFERENCE (Lat. *conferre,* "to bring together") (1) In general a meeting for consultation, discussion, instruction or the like; or any interview for interchange of views. The term is specifically applied to consultations between committees of the two Houses of Congress in the United States, and to similar consultations between delegates of the two Houses of Parliament in Great Britain. Such conferences are usually called to discuss the provisions of a bill with regard to which the two houses are disagreed, with the object of effecting an agreement between them.

(2) A term much used in ecclesiastical government, etc. The annual meetings of Wesleyan preachers in England for deliberation on the affairs of the body are called conferences. In the United States the Methodist Episcopal Church has an assembly called the general conference, which meets once in four years; numerous assemblies called annual conferences; district conferences; and quarterly conferences; these assemblies variously dealing with local or general interests of the Church. In the Roman Catholic Church there are instituted pastoral conferences, chapter conferences, etc.; and in various Protestant denominations there are stated local or general assemblies of chosen delegates from individual churches, who meet to consider or adjust denominational affairs.

(3) The word conference also covers international meetings, and there have been many noted international conferences, some of which have been of a religious nature. Of these latter a very notable gathering was the ecclesiastical conference called together by King James I of England and which met at Hampton Court Palace in 1604, for the establishment of a common creed. It led to King James' famous translation of the Bible which is still known to all Protestant English-speaking readers as the "Authorized Version." Another famous ecclesiastical gathering was that known as the Savoy House conference, which at a meeting held in 1661 made some important changes in the Prayer Book of the Established Church of England. Political conferences have been many and some of them important. The conferences of London and Geneva both held in 1864; two other conferences of London held respectively in 1867 and 1871 and the Balkan conference also held in London (1912–13) form links in the chain of modern history; while the conference of The Hague of 1899 and recent meetings of a similar nature have attracted general attention. See also PACTS AND CONFERENCES: WORLD WAR II.

CONFERVA (Lat. *con,* "together," and *fervere,* "to be hot"), kŏn-fĕr'va, a genus of green algæ. Most species are marine, though a few are freshwater. The name is also applied to a genus of the *chlorophyceæ.*

CONFESSION, *in criminal law,* the voluntary admission or declaration made by a person who has committed a crime or misdemeanor, to another, of the agency or participation which he had in the same. *Judicial* confessions are those made before a magistrate or in court in the due course of legal proceedings. *Extra-judicial* confessions are those made by the party elsewhere than before a magistrate or in open court. Confession is admissible only when voluntary; but if it is obtained by temporal inducement, threats, promise or hope of favor held out to the party in respect of his escape from the charge against him, by a person in authority, it is not allowed. Likewise, if the confession is made in answer to questions not containing or in any way implying threats or bribes, it is then admissible. A confession differs from a statement or declaration in that the former applies to an acknowledgment of guilt after the deed has been committed and does not apply to a mere statement or declaration of an independent fact from which such guilt may be inferred. The court primarily determines whether the confession is voluntary or not. If the various evidence conflicts as to whether the confession is voluntary, the court may leave it to the decision of the jury with the direction that they shall reject the confession, if on hearing the whole evidence, they are convinced that it was not the voluntary act of the defendant. See CRIMINAL LAW.

CONFESSION, Sacramental, the act of a penitent accusing himself of his sins to a priest who has power to grant absolution, it is called auricular confession because addressed to the ear (*auricula*) of the minister of the sacrament of penance, and not made in open congregation; though of course were such public confession to be made the priest would, unless the laws of the Church should forbid, possess the same power of absolution as in auricular confession. The law of the Catholic Church, as defined by the Council of Trent, requires that the faithful shall confess to a duly commissioned priest all their mortal sins, and are advised to confess venial sins, committed after baptism and since a previous confession and absolution, so far as they can recall them by a diligent examination of their conscience. The penitent is strictly required to confess all his mortal sins, their kinds and their number as well as he can recall them; wilful concealment of a mortal sin or even of what the penitent may erroneously deem a mortal sin, renders the confession of the penitent and the absolution of the minister null, and both of these acts must be done over again and made good. If a penitent, after examination of his conscience, fails to recall any mortal sin he is under obligation to confess that sin afterward and to receive absolution for it. See ABSOLUTION.

CONFESSION AND AVOIDANCE, a plea showing new facts by which it is designed to negative the allegations in the pleading of the adverse party. It may apply to the whole or to a part of the pleading, but if only to a part it must be so stated. This plea expressly or impliedly admits at least the apparent truth of the allegations of the plaintiff. All statements in confession and avoidance must be both specific and clear. Pleas in confession and avoidance must conclude with a verification.

They must plead matter either in excuse and justification or in discharge, as a release.

CONFESSION OF FAITH, Westminster, a document prepared by the Assembly of Divines which met at Westminister in obedience to an ordinance of Parliament issued 12 June 1643. The whole number of the assembly amounted to 174 members, 32 of whom were members of Parliament appointed as lay assessors. The greater part of the assembly were Puritans. One of the chief results of the deliberations of the Assembly was the framing of the Confession of Faith, intended to be that of the national Church of Great Britain. In England it nominally held this position for a short time. On the return of the Scottish commissioners it was laid before the General Assembly of the Church of Scotland, by whom it was adopted as the creed of the Church by the act of assembly of 27 Aug. 1647. It has been adopted by the other Presbyterian churches generally, in some cases, however, with certain reservations. Its theology and discipline are thoroughly Calvinistic. See CREEDS; WESTMINISTER ASSEMBLY.

CONFESSIONAL, in Roman Catholic churches and chapels, a kind of enclosed seat, stall or box in which the priest sits to hear persons confess their sins. The confessional is often not unlike a sentry-box, the priest sitting within and the penitent kneeling without and speaking through an aperture. Many confessionals are in three divisions or compartments, the centre, for the reception of the priest; the side compartments, which communicate with the centre by grated apertures, are for the penitents. The word confessional is often used in the sense of the tomb of a martyr or confessor. Sometimes an altar was erected over the grave and the name was extended to the altar. If a church was erected over the tomb another altar was placed, in the building, exactly over the tomb with its altar below. The upper altar was called a confession or confessional.

CONFESSIONS, Les, an autobiographical work of Jean Jacques Rousseau (q.v.). It was written during the six most agitated years of his life, from 1765 to 1770; and his state of health at this time, both mental and bodily, may account for some of its peculiarities. The first six books were not published until 1781, and the second six not until 1788. According to more than one critic, the 'Confessions,' however charming as literature, are to be taken as documentary evidence with great reserve. They form practically a complete life of Rousseau from his earliest years, in which he discloses not only all his own weaknesses, but the faults of those who had been his friends and intimates.

CONFESSIONS OF AN ENGLISH OPIUM EATER. The 'Confessions' exist in two distinct forms. The earliest form, containing the two papers printed in the *London Magazine* for September and October 1821, appeared the next year (1822) and passed through no less than six editions in the next 30 years without essential change. In 1845 De Quincey began a series of articles in *Blackwood's Magazine,* under the title "Suspiria de Profundis, being a sequel to the Confessions of an English Opium Eater;" but the series ran through only four numbers. In 1856, however, when he collected and arranged his writing for a uniform edition, he rewrote the volume of 1822 throughout, enlarging it to nearly three times its original dimensions. The introductory chapter, in particular, which in 1822 had been a brief account of his early years, was now enormously expanded by the insertion of some matter from the Suspiria and by crowding into it a multitude of incidents and experiences, many of which have no connection with opium eating and some of which seem to have been drawn rather from his imagination than from his memory.

This enlarged edition is really a vivid picture of De Quincey himself, not only as the opium eater, but as the scholar, the critic, the gossip. His mind was abnormally active; but he could never follow a straight line of thought or course of narrative. Everything reminds him of something else. But if the story takes a long time to get anywhere, its path is set thick with curious incident and subtle observation. Even the dreams and phantasies of the opium eater were not due principally to opium. De Quincey was a dreamer always. His early childhood, years before he ever tasted the drug, was largely passed in a mood of waking dream; in his autobiographic papers we find record of hours when visions in sight or sound, vague and solemn, came upon him with the compelling sense of reality. The effect of opium in later years seems to have been to recall these earlier experiences with strange vividness, to combine other incidents with them, and to repeat them habitually in his dreams. Indeed, the very best specimens of what he calls his dream phantasy seem not to have been suggested by any particular experience, or to have owed anything to the influence of opium. That wonderful fragment, the Three Ladies of Sorrow, from the Suspiria, is an embodiment of three of the darkest forms of human grief, mysterious but strangely vivid, but without a hint of anything morbid in its genesis — a work of the pure creative imagination.

It is in such passages as this we may see at its best that particular form of prose-poetry which De Quincey claims to have been of his own invention. He always admired the large, sonorous style of the early 17th century men, and sometimes caught their manner very successfully. In the 1822 edition of the 'Confessions' is an apostrophe to opium, imitated from Walter Raleigh's famous apostrophe to death, which is quite as lofty as its original. This elaborated style is indeed ill adapted to the rambling gossip that makes up so large a part of De Quincey's writing, but his passages of revery and dream owe their strange effect upon our sensibilities very largely to their stately movement and music. Consult Saintsbury, 'Essays in English Literature' (1780–1860); Stephen, Leslie, 'Hours in a Library' (1st series); Winchester, C. T., 'A Group of English Essayists.'

CALEB T. WINCHESTER.

CONFESSIONS OF SAINT AUGUSTINE, The. Autobiographies are as a rule utterly conventional and commonplace, interesting only to those immediately concerned with the author. We have any number of them that are waste paper, but a few of them like Cellini's life of himself, Montaigne's 'Essays,' and Rousseau's 'Confessions,' show that when a

man pours himself out he can make a supremely human document that is enduring literature. Among these immortal autobiographies, probably the work that has had most influence, in the intellectual world at least, is 'The Confessions of Saint Augustine' (354–430 A.D.). He wrote them shortly after he became bishop of Hippo, just before 400 A.D., when he was in his early forties. The fact that the book has maintained its popularity now for over 1,500 years shows from how close to the human heart it is written. For the Confessions are the history of Augustine's heart. We have two other sets of autobiographic documents from his hands, the 'Retractations,' which are the story of his mind, and his letters, which give an account of his activities. These two are little known beyond the narrow circle of students of theology and Church history. Most writers of autobiography seem to think that it is the story of their minds and actions that will interest men around them. Augustine's immortal record of his affections which still continues to attract the attention of each generation of thinkers shows that it is by the heart men live. Saint Augustine's Confessions are not, however, as so many people imagine, an account of past deeds and above all not an avowal of youthful transgressions as such. The word confession is used in the biblical sense of the Latin word *confiteri* as an acknowledgment. Augustine's Confessions are quite literally the acknowledgment of a soul forced to admire the action of God within itself, though it has to admit the many obstacles that it placed in the way of Divine influence. It is full of the psychology of human conduct, though so many people seem to think that only in comparatively recent years have men begun to reflect thus carefully on their inner activities. It has been said of the book, "neither in respect of penetrating analysis of the most complex impressions of the soul nor communicative feeling, nor elevation of sentiment, nor depth of philosophic views, is there any book like it in all literature." As Augustine was one of the profoundest intellectual geniuses of human history, famous above all for his marvelous insight into human motives and his capacity to describe the various states of the soul and the facts of the spiritual world, it can be readily understood why this little book in which he set no barriers in his desire to reveal for God's honor and glory all that had gone on within him in the motivation of his life should be of supreme human interest. He was a psychologist of the psychologists, and while he was the greatest of the Fathers of the Church in the sense of being the authoritative expounder of the esoteric meaning of more of her doctrines than any other, he is also the patron and master in their own estimation of more of the heretics of the ages than any other, because the matter that he dealt with was so profound that it is rather easy to twist his meaning to anyone that the disciple may wish to have in order to support his own opinion. The psychology of the 'Confessions' has probably more interest for our generation than other features of the work. The excursions into child psychology in the first book exemplifying that a child has definite tendencies away from law and order toward neglect of study and precept, learns not by rules but by example, and observes closely the inconsistencies of elders, have drawn many a one to reading the rest of the book. The boy Augustine was very human, hated Greek and liked "the empty tales of the poets," and blames like everyone else the method of his education and yet confesses how much more of good than of ill came to him from it. He went through his salad years when he liked to pity himself and has a chapter "On Weeping and Why It is Pleasant to Be Wretched." Above all he shows very clearly how much personal affection meant to him. The death of a friend overwhelms him, but companions serve to distract him; his mother rescues him, not his principles; he comes under the personal influence of Ambrose; always it is personality that draws him. He soon came to realize that the claims of his intellect for satisfaction were incapable of fulfilment. "For I withheld my heart from all assent dreading a downfall; and came nearer being killed by the suspense. For I wished to be as assured of the things I saw not, as I was that seven and three are ten. . . . But as it happens that one who has tried a bad physician fears to trust himself to a good one, so was it with the health of my soul, which could not be healed, but by believing, and for fear of believing falsehoods, refused to be cured." (Book VI, chap. 4). Augustine's 'Confessions' will probably always continue to be a favorite book for those who like himself have learned the lesson that the heart life of man is ever so much more important than his intellectual life. Consult 'The Confessions of Saint Augustine' (The Ancient and Modern Library of Theological Literature, New York 1886); 'St. Augustine's Confessions' (New York 1927); Farrar, 'Lives of the Fathers' (London 1889); Harnack, 'Augustins Confessionen' (Giessen 1895). Many modern writers on philosophic subjects have monographs on some phase of Augustine's thought: Renan, Eucken, Spalding, McCabe, Reuter, etc.

JAMES J. WALSH,
Author of 'Catholic Churchmen in Science.'

CONFESSOR, in the Roman Catholic Church has two principal significations. (1) Denoting a canonized male saint outside of the classes of the apostles, evangelists and martyrs. The only saints, who in the earliest times were publicly venerated in the Church after death were, in addition to the Blessed Virgin and the apostles, the martyrs; and such are all the saints named in the Roman canon of the Mass, though the Milan canon (Ambrosian) has the name of other saints. (2) the other meaning of the word confessor, the priest who hears confessions, answers to the more correct Latin word *confessarius.* The confessor, minister of the sacrament of penance, does not exercise that ministry simply in virtue of his having received priestly order: he must receive jurisdiction from the bishop of the diocese. The general law of the Church requires each of the faithful to resort to the confessional at least once in every 12 months, and to make confession each to his own parochus or parish priest; but under the law they may now lawfully confess to any priest who has due authorization from the bishop.

CONFIDENTIAL OR PRIVILEGED COMMUNICATION. In law, a communication made by one person to another which the

latter cannot be compelled to give in evidence as a witness. The laws of the United States and of some other countries are, that all communications made between a client and his agent, between the agent and the counsel in a suit, or between the several parties to a suit, shall be treated as confidential; but in some minor points the practice varies in the different States. Legal agents are of course required to produce any papers entrusted to them by their clients, which the clients themselves would otherwise have been required to produce. The privilege of confidentiality regarding disclosures made to a medical adviser, even although it may have been necessary for the patient to make them in order to enable the physician to understand and treat his case, have not been defined by statute, but the custom has been that such communications are privileged. The same holds true regarding confessions made to a priest. No instances are cited where the confession of a penitent has ever been revealed by a priest. Communications made between husband and wife during marriage are in some States not admissible as evidence, although in most civil cases a husband and wife may legally be called as witnesses against each other. The laws in the United States differ in different States regarding the admission of testimony of husband or wife for or against each other.

CONFIRMATION (Lat. *confirmare,* «to make strong»), one of the seven sacraments of the Roman Catholic Church; in the Lutheran, the Anglican and the Protestant Episcopal Church confirmation is not a sacrament, but only a solemn rite wherein the one who is confirmed renews in the face of the Church the promises made on his behalf by his sponsors in baptism. Confirmation admits the person upon whom it is conferred to the status of a communicant and to full membership in the Church. In the early times of the Catholic Church the sacrament or rite of confirmation was administered immediately after baptism, even of infants: hence the two rites have often been, even by orthodox writers, viewed as one; and in the Greek and Oriental churches this custom still persists. But in the present discipline of the Latin Church confirmation is usually not administered till about the 8th year, though a child might be held competent to receive it at the age of seven. It is customary for the confirmant to take an additional name as a memorial of the rite. In administering it the bishop — and the bishop is the ordinary minister of this sacrament — with chrism (q.v.) marks the sign of the cross on the forehead of the recipient, and gives him a gentle slap on the cheek, in signification that he must be ready to suffer for Christ's name's sake. The formula of words used by the bishop in signing the confirmant is, «I sign thee with the sign of the cross and I confirm thee with the chrism of salvation, in the name of the Father, and of the Son, and of the Holy Ghost.»

CONFISCATION. *In international law,* the act of one state in appropriating property belonging to another state or to its subjects, either as a belligerent right or as a punishment for carrying contraband of war, blockade running or the like. The term is used also to indicate the seizure of property by the state as an act of punishment for non-compliance with the law, as for violation of internal revenue regulations.

In English law some early authorities, including Blackstone, seem to use the term as a synonym for «forfeiture,» though at common law it has been held to embrace only seizure by the Crown of goods found on a felon, but not claimed by him, and to articles dropped by a thief fleeing from justice. (See FORFEITURE). By statute in England, passed in 1914, enemy property which had been subjected to confiscation by the Crown was placed under the care of a legal custodian.

In Roman law goods which had been subjected to confiscation by the state were called by the civilians *bona confiscata,* and belonged to the *fiscus,* or imperial treasury.

One form of confiscation long known to international law is called *angaria* or *angary,* which is defined as the seizure or destruction of neutral property by a belligerent when urgently necessary, with due compensation later. This right was exercised in the Franco-Prussian War by Germany.

In the United States, enemy property has frequently been confiscated under international law and by Federal statutes. In 1861 and 1862, during the Civil War, Federal statutes were passed providing for the confiscation of property used for insurrectionary purposes, and these statutes were later held to be constitutional by the Supreme Court. Congress, dating from the adoption of the Constitution, has had the exclusive power of confiscation of alien property. Shortly after the outbreak of hostilities with European powers in the spring of 1917, the United States seized a large number of ships belonging to Germany and Austria found afloat in various ports, under a well-known rule of international law justifying the act. By a Federal statute enacted 6 Oct. 1917, a legal custodian was appointed for all alien enemy property confiscated in the United States during the war then pending.

By proclamation of the President of the United States, 20 March 1918, under the authority conferred upon him by the Naval Bill of 1917, «in exercise of our indisputable rights and in accordance with the law and practice of nations,» 68 ships, representing about 470,000 tons, belonging to Holland, lying in United States ports, were confiscated. The seizure was condemned by Germany and also in other quarters, as in Holland, as a violation of the rules of international law. It has been vigorously defended, however, as lawful by eminent jurists and justified by the law of *angaria* or *angary,* long recognized in legal usage, as stated above, and also as incorporated in The Hague conventions of 1899 and 1907. At about the same time Great Britain, claiming under the same right, took control of a number of Dutch ships representing about 400,000 tonnage.

CONFISCATION ACTS OF 1861, 1862, United States statutes «to confiscate property used for insurrectionary purposes.» See CONFISCATION.

CONFUCIUS, kŏn-fū'shĭ-ŭs (Latinized form of Chinese K'ung-futze, the Master Kung), Chinese philosopher: b. province of Shan-tung, about 551 B.C.; d. in Lu, 478 B.C. His father, Kung Shuh-liang-heh, who was of royal descent, died three years later, and the

boy was reared in comparative poverty by his mother, Ching-tsai. At the age of 17 he was made inspector of corn-markets, keeper of granaries and overseer of public fields. Here he made such a good record that he gained the favor of the governor. At 19 he married, and some four years later he began his career as a teacher. By 520 he had worked out the general direction of his philosophy from which he departed very little thereafter. The disregard for the moral law then prevalent in the province of Lu induced him to make a study of the ancient writings of China. At the age of 22 he had already become a well-known teacher and expounder of the ancient writings, and many noted persons gathered at his house to gain instruction from him. He had no intention of teaching a new religion or philosophy. He aimed to bring men to a realization of the utility, beauty and truth of the old. He bent all his energies to reviving old customs; and in this he set a fashion still strong in China to-day. In 517 B.C. he was induced, by two members of one of the principal houses in Lu who had joined his band of disciples, to visit the capital with them, where he had interviews with Lao-tse, the founder of Taoism. Though temporarily driven from Lu to Tsi by a revolution, he soon returned thither with an increasing following; and there he remained for 15 years, during which he kept constantly in view his mission as a philosophical teacher. At the age of 52 he was made chief magistrate of the city of Chung-too. So striking a reformation was effected by him that he was chosen for higher posts, became minister of crime, and with the aid of two powerful disciples, elevated the state of Lu to a leading position in the kingdom. Through the political intrigues of the governors of neighboring states Confucius was removed from office (496 B.C.), and became a wanderer in many parts of China for 13 years.

In 485 he returned to Lu, but would not take office. The death of his favorite disciples, Yen Hwin and Tze-lu, in 481 and 478, did much to further his own, which took place in the latter year. Confucius left no work detailing his moral and social system. His five canonical books 'Yih-king'; the 'Shu-king'; the 'Shi-king'; the 'Le-king'; and the 'Chun-tsien' are grouped with the 'Four Books,' by his disciples, the 'Ta-hëo or Great Study'; the 'Chung-yung or Invariable Mean'; the 'Tun-yu or Philosophical Dialogues'; and the 'hi-tse,' written by Meng-tse or Mencius. (Consult 'Sacred Books of the East'). The teaching of Confucius has had, and still has, an immense influence in China, though he can hardly be said to have founded a religion or a philosophy. All his teaching was devoted to practical morality and to the duties of man in this world in relation to his fellowmen. In it was summed up the wisdom acquired by his own insight and experience, and that derived from the teaching of the sages of antiquity. He sought to attain a happy tranquillity throughout the Chinese Empire which could, he believed, be attained by the observance of the five obligations of human society: Those between sovereign and minister; father and son; husband and wife; elder and younger brother; and between friends. It was, according to his teaching, incumbent upon all to perform the reciprocal duties arising from each relationship. In his teachings there is a strong feudal leaning which advocates almost unlimited authority for the sovereign over the minister; for the father over the son; the husband over the wife; the elder brother over the younger. Subordination to superiors he looked upon as one of the greatest of all essentials for the existence and proper conduct of the state. To these must be added virtuous conduct among all and upright dealing among friends. The education of the young he declared to be the foundation of the welfare of the state. Democracy had not yet made its appearance in China and Confucius' ideal of government was a paternal despotism wisely and honestly directed and administered. This position he modified by the assertion that a ruler's maintenance of power should depend upon his just and upright conduct and his honest endeavor to make his government good.

His philosophy is not deep, but its general tendency is good, affecting strongly the usual intercourses of life. It is thoroughly practical and terrestrial, and it avoids theology and metaphysics and all those subjects that Confucius could not make clear by example and apply rigidly as rules of life. He never attempted to solve questions that he considered beyond his reach. Fast and hard rules of morality and action he made to govern the intercourse of the human race; and in this sense he tied China to a system for hundreds of years. He occupied himself altogether with the problems of this world and let the next take care of itself. From the Christian point of view, therefore, there is nothing spiritual about the work of Confucius. His attitude toward spiritual questions he has put clearly upon record: «To give one's self up earnestly to the duties incumbent upon men and, while respecting spiritual beings, to keep aloof from them, may be considered wisdom.» His teachings have left China more materialistic and less spiritual than is any of the other great nations. While he instilled morality and national and individual honesty, yet more than 24 centuries of his teachings have not driven superstition and ignorance out of the land, nor improved the government, nor raised the condition of the masses of the people, nor driven illiteracy out of the nation. They have retarded the progress of democracy in a people, in spirit, essentially democratic, and they have encased the national spirit in a hard shell of rules and conventionality from which it has just begun to make spasmodic efforts to free itself. The thinking people have, however, begun to realize dimly that his philosophy is, in many ways, unsuited to an age in which the spirit of all progressive government is expressed by the will of the people. Since the overthrow of the monarchy, candidates for public offices are no longer required as formerly to pass a rigid examination in the «nine classics.» As the teachings of Confucius gave their strong sanction and support to the despotic form of government which ruled China, almost uninterruptedly for more than 30 centuries, the royal family and the nobility naturally gave to it an importance that it did not intrinsically possess. They saw to it that there were magnificent shrines erected to Confucius in every city, town and community throughout the Chinese Empire, and that his priests were specially honored, so that they became one of the mightiest forces in the

direction of the life of China. However honest they may have been in the fulfilment of their great duties and obligations, they have hung upon the chariot wheels of progress.

JOHN HUBERT CORNYN,
Editorial Staff of the Americana.

CONGÉ D'ÉLIRE, kôn'-zhā-dā-lēr (Fr. "leave to elect"), in Great Britain, the warrant of the sovereign, as head of the Church of England, authorizing the dean and chapter of a vacant see to proceed with a new election. The nomination to bishoprics, originally understood to have been vested in the Christian people, who made it by election, was afterward transferred to the sovereigns of most states, and remained with them till the 11th century, when, with the assistance of the pope, it was wrested from them and conferred upon the clergy. In England, the Constitutions of Clarendon, in 1164, conferred the election on the chapters, and this right was formally confirmed by Magna Charta, subject, however, to a right in the sovereign to grant a *congé d'élire,* and also to confirm the chapter's choice. Thus matters remained till the Reformation, when the crown made an encroachment, and provided by statute (25 Henry VIII c. 20, 1534), that though the dean and chapter were still required to go through the form of an election, the person to be chosen should previously be absolutely fixed by the sovereign. This act is still the regulating statute, and not only provides that on every vacancy in a see the sovereign may grant a license to proceed to the election of a successor, and with it a letter containing the name of the person to be elected, but that, if the dean and chapter delay the election beyond 12 days or elect any other person than the one named in the letter, or do anything else in contravention of the act, they incur the penalties of a *præmunire,* that is, forfeiture of goods, deprivation of certain civil rights and imprisonment. Any bishop or archbishop neglecting to assist at the consecration and investment of the bishop-elect, within 20 days after the legal annoucement of his election, is liable also to the penalties of *praemunire.*

CONGER, kŏn'gẽr, **Edwin Hurd,** American diplomat: b. Knox County, Ill., March 7, 1843; d. Pasadena, Calif., May 18, 1907. He was graduated at Lombard University in 1862, served in the Union army 1862–65, was graduated at the Albany Law School in 1866, and was elected to Congress in 1884; and twice was re-elected as a Republican. He was Minister to Brazil (1890–98), and then to China. Throughout the Boxer Rebellion (see BOXERS) of 1900 he was at his post in Peking, being imprisoned with his family and the entire diplomatic corps in the British legation during June–August. His rescue on August 20 was effected by the allied powers barely in time to save him and his colleagues from a general massacre. He was appointed Ambassador to Mexico early in 1905, but resigned in August of that year.

CONGER EEL, a species of marine eel (*Leptocephalus conger*) with a long dorsal fin reaching forward nearly to the head and continuous posteriorly with the caudal; the pectoral fins present; strong, close-set teeth in the jaws; mouth and eyes large, and scales absent. The conger is a large eel, the ordinary specimens commonly captured along the New England shores being four feet long, while those taken in the open sea are six to eight feet, and weigh 50 to 60 pounds, and, in rare cases, upward of 100 pounds. It is common off the coasts of Europe, including the Mediterranean, Africa as far south as Saint Helena, Tasmania, and Japan. The morris, the larval state of the conger, attains a length of five or six inches, when a transformation takes place, pigment being developed, and the body becoming round and much shorter. The mature congers repair to very deep water for spawning, after which they die.

CONGESTION (Lat. *congestio,* "accumulation"), an abnormal amount of blood in the vessels which is caused by pressure on the arteries or by obstruction to the emptying of the veins. It is usually due to some acute inflammatory reaction, causing rapidity of the heart beat or dilatation of the blood vessels with consequent congestion in some area. In venous congestion, as a rule, the cause is due to some constriction of the venous return to the heart. Congestion is present during many diseases, and may be caused temporarily by over exertion, drugs, intoxication or a severe blow, fall or cold. See COLD.

CONGLETON, England, a market town and borough of Cheshire, in a deep valley, on the Dane, 26 miles south of Manchester. Among the chief buildings are the town hall and the grammar school. Congleton is a seat of the silk manufacture, ribbons, handkerchiefs, and other articles being made; it also carries on fustian-cutting, the manufacture of agricultural implements, rope-making, and brewing. Near it are collieries and quarries, and salt is abundant in the neighborhood. Pop. 14,940.

CONGLOMERATE (Lat. *conglomeratus,* "rolled together"), or **PUDDING-STONE,** a firm sedimentary rock made up of rounded detrital pebbles and even boulders, the interstices usually filled with sand or other fine-grained rock material. Silica is the commonest cementing material, calcite and limonite coming next. The pebbles and boulders may be of any kind of rock, though quartz and quartzite are the most frequent, since they are the most resistant material in gravels. According to the character of the pebbles, different names are given, as quartz conglomerate, limestone conglomerate, etc. Conglomerates grade through pebbly sands and sandstones into true sands and sandstones. Under dynamic stress, in the folding of rock strata, the pebbles of a conglomerate may be much distorted, and by further metamorphism a conglomerate may pass into a gneiss. Some notable conglomerates are the copper-bearing Calumet and Hecla conglomerate on the Keweenaw Peninsula, Michigan, of Algonkian Age; the great conglomerate at the base of the coal measures of Carboniferous Age, in Pennsylvania and adjacent states; the Roxbury conglomerate of uncertain age, near Boston, Mass.; and the famous "banket," possibly of Permian Age, on which are located the great gold mines of the Transvaal. See BRECCIA; GNEISS; ROCKS; SANDSTONE.

CONGO FREE STATE. See BELGIAN CONGO.

CONGO RIVER, The, is the largest in Africa, and in respect of its basin it is the

largest in the world; it was formerly known as the Zaire. Its main headstream is the Chambezi, which takes its rise in British territory on the southern slope of the plateau between lakes Nyasa and Tanganyika. The Chambezi, augmented by the waters of the Karungu, flows into Lake Bangweulu, whence it issues under the name Luapula. The river then flows north, receiving the Lukuga (which issues from Lake Tanganyika) and the Lualaba, and continuing north-northwest as the Congo. At about the place where the river crosses the equator are seven falls known as Stanley Falls, below which are cataracts and rapids. The river turns to the west, and then southward, emptying into the Atlantic Ocean, and on its course receiving many tributaries, notably the Ubanghi on its right bank, and the Kasai River on its left. The Congo has an estimated length of 3,000 miles, and it drains an area of some 1,600,000 square miles. Ocean-going steamships can ascend the Congo for a distance of 110 miles to Matadi, where rapids are first encountered. A railroad affords communication from Matadi to Stanley Pool, where Léopoldville stands, and from that point to Stanley Falls, a distance of 1,068 miles, the Congo is navigable for steamers of light draught. From Stanley Falls to Ponthierville, 78 miles, where the river again becomes navigable, a railroad has been constructed; and from Kindu (200 miles above Ponthierville) to Kongolo, where it again becomes open for steamers, another line, 217 miles in length, has been built.

The Congo was first made known to Europeans by Diogo Cam (q.v.), the Portuguese explorer, who reached its mouth in 1484–85. It was not, however, until Capt. J. K. Tuckey, of the British Navy, explored the estuary of the river in 1818, that any considerable attention was devoted to it. The discoveries of David Livingstone (q.v.) on the Luapula and Lualaba in 1867–71, and the later journey of Sir Henry Morton Stanley (q.v.) from the Lualaba to the mouth of the Congo in 1876–77, revealed the full extent of the river. From the labors of the latter resulted the founding of the Congo Free State subsequently known as the Belgian Congo (q.v.).

CONGO SNAKE, one of the slender amphibians of the family *Amphiumidae,* which take an intermediate place between the coecilians and the salamanders as the lowest family of the tailed (urodelous) amphibians. Several genera occur in Asia and North America. The giant "salamander" (*Cryptobranchus maximus*) of the mountain streams of Japan, sometimes more than five feet long, and the American hellbender (q.v.), are of the same family. The term "Congo-snake," however, belongs specifically to the typical genus and species, *Amphiuma means,* which inhabits suitable localities in all the warmer parts of the United States, where it receives its name from the Negroes of the Southern States. It is an eel-like creature, with very small, three-toed and almost useless limbs, one pair near the head and the other almost at the caudal extremity, which haunts shallow stagnant waters, is numerous in the Southern ricefields, and is superstitiously feared by many persons although perfectly harmless. It feeds on small fishes, snails, crayfish, and insects, which it darts upon in the water or roots out of the mud. It reproduces by eggs, deposited at the end of the summer in a damp place, as under a rotting log, which, provided with shells, are connected by a gelatinous cord, and are protected by the female who coils her body about them and afterward takes care of the young. The embryos have well-developed external gills, but these disappear with growth, and even gill-clefts are greatly reduced in adults.

CONGREGATION (Fr. *congregation,* Lat. *congregatio,* from *congregare,* "to come together in a body"), a gathering or collection of persons; usually a religious assembly; in its most ordinary use, an assembly of Christians met in one place for worship. In the Roman Catholic Church, it often designates a board of cardinals, prelates, and divines, to which is entrusted the management of some important branch of the affairs of the Church. Thus, the Congregation of the Index examines books and decides on their fitness for general perusal. The *Congregatio de Propaganda Fide* is instituted for the propagation of the Roman Catholic faith, and the government of the Church in non-Catholic countries. The Congregation of Relics inquires into the genuineness of supposed relics. The Congregation of the Holy Office takes cognizance of heresies. The Congregation of Rites, regulates the festivals and offices of new saints. There are numerous other Congregations. The word is also used in the Roman Catholic Church to describe communities of ecclesiastics who live together under rule, but without being bound by vow, or at least by solemn vow. Such are the Congregation of the Oratory and the Congregation of the Most Holy Redeemer, usually called Redemptorists. See CONGREGATION OF OUR LADY OF CALVARY; CONGREGATION OF THE MOTHER OF GOD; FREE CONGREGATIONS.

CONGREGATION OF BISHOPS; CONGREGATION OF THE CONSISTORY. See CONGREGATIONS, THE SACRED.

CONGREGATION OF OUR LADY OF CALVARY, a French order of Benedictine nuns. It had a somewhat stormy career. Organized at Poitiers in the early part of the 17th century, the society, after having played an important part in the religious life of France, was broken up during the Revolution and its members dispersed over the face of Europe. The order was reorganized, and again secured a firm footing in the land of its birth. See CONGREGATION.

CONGREGATION OF THE MOTHER OF GOD, a monastic order instituted at Lucca, Tuscany, about 1574 by Giovanni Leonardi. It was originally known as Clerks Secular of the Blessed Virgin, and later, while Leonardi was still alive, as Clerks Regular of the Blessed Virgin, a name it kept until the society was suppressed in 1867. On its reorganization the society was known popularly as the Congregation of the Mother of God.

CONGREGATIONAL METHODIST CHURCH, an ecclesiastical body in the United States, organized in Monroe County, Ga., by seceders, lay and clerical, from the Methodist Episcopal Church, in 1852. The movement was in the direction of a more democratic or congregational polity, designed to give the members of individual churches larger and more direct control of their own affairs; but the body still preserves the more essential forms

of organization and procedure, such as the conference system, etc., characteristic of the Methodist Episcopal Church. It has a membership of over 9,000 distributed among about 145 churches.

CONGREGATIONALISM had its origin in an attempt in England to carry the principles of the Protestant Reformation regarding the authority of Scripture to their radical consequences. Accepting the Bible as the sole rule of faith and practice, the founders of Congregationalism sought to find in it not merely an authoritative source of Christian doctrine; but, also, a complete, adequate and binding pattern of church government and organization. They grew out of the Puritan party of the reign of Queen Elizabeth, of which party they were the most advanced wing. They shared fully the intense Calvinism of that party and differed from it only in matters affecting church organization and government. The great majority of the Puritans held to the conception of a national Church, of which all baptized and non-excommunicated inhabitants of the kingdom were members. The reformation of this Church, though earnestly to be sought by private Christians, they viewed as ultimately the work of the national government, and hence they held it to be a duty to remain in the Church of England, while laboring for what seemed to them its betterment. This reformation involved, in the conception of the Puritans generally, the establishment everywhere of a learned, earnest, preaching ministry; of efficient discipline; of what they deemed a more scriptural organization of the Church; and the disuse of such vestments and forms of worship as seemed to them to be without biblical authority or to savor too strongly of Roman usages.

The founders of Congregationalism sympathized with these aims and criticisms of the Puritans, but, unlike the majority of that party, they believed that the reforms which they desired in the Church of England should come about through individual initiative, by the separation from that Church of those who criticised it. Hence the early Congregationalists of England were called «Separatists.» They rejected the thought of a national Church. They held that the only proper form of the visible Church is the local congregation, composed of a company of professed disciples of Christ who can claim personal religious experience, and are united to Christ and to one another by a voluntary covenant which transforms a company of Christians into a Church. Of these congregations Christ is the immediate head. Each, they conceived, is completely self-governing, choosing its own officers and administering its own discipline. While no earthly authority outside of such a Church has jurisdiction over it, each such congregation owes advice and aid to its sister congregations as necessity may require. This mutual responsibility and helpfulness has always led American Congregationalists to reject the name «Independent» which is popularly attached to the churches of this order in Great Britain. The officers of such a local Church were conceived by the founders of Congregationalism, following what they thought the New Testament model, to be a «pastor,» and a «teacher» who should preach and administer the sacraments; a «ruling elder» who should aid the «pastor» and «teacher» in the administration of discipline; «deacons» to administer the financial affairs and charities of the congregation, and «widows» to care for those in illness and the poor. In their revolt from the prescribed liturgy of the Church of England they held that public prayer should be wholly free; and, like the Calvinists generally, they gave the chief place in public worship to the sermon.

Though Richard Fitz and his associates, whose congregation at London was broken up by the English government in 1567, may be deemed the earliest organized Congregationalists, the first clear presentation of Congregational principles was made in the works of Robert Browne, a graduate of the University of Cambridge in 1572, who passed from Puritanism to Separatism, probably in 1579, organized a church at Norwich in 1580 or 1581, and issued a series of tracts in defense of his views, from his exile at Middleburg in Holland, in 1582. Though Browne not long after conformed to the Church of England, a similar work was taken up by others, notably by Henry Barrowe, a lawyer of London, and Rev. John Greenwood and Rev. Francis Johnson in the same city, where a Congregational church was organized in 1592. In 1593 Barrowe, Greenwood and Rev. John Penry were hanged at London for opposing the ecclesiastical authority of Queen Elizabeth, and the Church in London was driven into exile. It found a refuge in Amsterdam under the pastoral care of Francis Johnson and Henry Ainsworth.

Contemporaneously with the later of these events, an apparently independent movement in the vicinity of Gainsborough and Scrooby, led at first by William Brewster, the postmaster at Scrooby, Rev. Richard Clyfton, rector at Babworth, and later also by Rev. John Robinson and Rev. John Smyth, resulted in the organization, about 1606, of congregations at Scrooby and Gainsborough, which were compelled to seek refuge speedily in Holland. That of Scrooby settled, in 1609, at Leyden under the pastoral care of Robinson, and a portion of this congregation, led by William Brewster, William Bradford and Edward Winslow, crossed the Atlantic in the *Mayflower,* and laid the foundations of Plymouth Colony in 1620, thus establishing the first of the Congregational colonies in America.

The settlers of Plymouth were Separatists, but during the years immediately succeeding their establishment in the New World, the course of politics in England under James I and Charles I was such as to lead many of the Puritans to despair of the attainment of the reforms they desired in Church and State in the home land. The consequence was a large Puritan emigration across the Atlantic; and the establishment, in the course of a decade (1628–38), of the three Congregational colonies of Massachusetts Bay, Connecticut and New Haven. These Puritan settlers were all led by the radical development of their own principles in a new environment, and the influence of Plymouth example, to establish churches on the Congregational model, at their settlement in New England.

These colonies differed slightly from one another in the degree in which they applied theocratic principles to the organization of the State. In Massachusetts from 1631 to 1664, and

in New Haven from 1639 to 1665, when New Haven was absorbed in the Connecticut Colony, the franchise was confined to church members. In Connecticut and Plymouth colonies no such restriction existed. Doctrinal discussion aroused by Mrs. Anne Hutchinson and her adherents at Boston occasioned the meeting of the first "Synod" or council representative of the Congregational churches of New England, in 1637. At the Cambridge Synod in 1648, these churches, by their pastors and delegates there assembled, adopted the "Cambridge Platform" as a compact manual expressive of their views of the organization, officers and discipline of the churches. The first century of New England Congregationalism saw, however, little theological debate, for the New England churches stood on the common doctrinal ground of Calvinistic Puritanism. The chief controversy of this period was that regarding church membership known as the "Half Way Covenant" discussion. In the view of the founders of Congregationalism the reception of a parent to church membership by "owning the covenant" involved the admission into church membership of his immature children. But adult membership implied experimental Christian character. When the children of the first settlers began to grow to maturity the question of their status forced itself, therefore, on the attention of the churches. A ministerial convention, representative of Massachusetts and Connecticut, held at Boston in 1657, and a "Synod" of the Massachusetts churches convened in 1662, decided that such as were church members in childhood by reason of their parents' membership could, when they in turn became parents, bring their children to baptism, and could confer upon such children the same degree of membership which they themselves possessed; but unless consciously and personally of Christian experience could not vote on ecclesiastical questions or partake of the Lord's Supper. Hence a distinction between members in "full communion" and in "half way covenant" was made, which continued till early in the 19th century, when it disappeared, largely owing to the opposition which Jonathan Edwards and his disciples had manifested to it from 1749 onward.

Congregationalism, like the Calvinistic churches in general, believed in the necessity of education, and therefore the New England colonies speedily after their foundation established schools, and planted Harvard College in 1636. Yale College followed in 1701. This spirit has characterized Congregationalism throughout its history and has led Congregationalists to be pre-eminently founders of schools and colleges as they have extended westward in the United States. The elaborate system of church officers already described, and believed by the founders of Congregationalism to be scriptural, outlasted the first generation of the settlers of New England in only a few instances. While they existed "pastor," "teacher" and "ruling elder" all received salaries from the churches they served; but in most of the New England churches "teachers" and "ruling elders" soon disappeared, leaving only a pastor and a variable number of deacons. The more modern growth of organization and methods of Christian work has led to the establishment of other officers, such as a clerk, a treasurer, a Sunday-school superintendent, and often one or more standing committees, and no feeling now exists that officers should be limited to those mentioned in the New Testament as possessed by the early Church. The pastor remains, with rare exceptions, the only salaried officer. The support of public worship which was originally by voluntary gifts, and has always been so in Great Britain, became, between 1638 and 1655, a matter of public taxation in all the Congregational colonies. In Connecticut this relation to the State which made Congregationalism practically a State-supported Church lasted till 1818, and in Massachusetts till 1834; but since the latter date Congregationalism has nowhere enjoyed State aid.

The high-wrought spiritual impulse manifested by the first settlers of New England was followed by a period of decreasing religious interest affecting the second, third and fourth generations on New England soil. This condition was terminated by a series of "revivals," of which the first manifestation was in that at Northampton, Mass., under the pastorate of Rev. Jonathan Edwards in 1734, and of which the culminating expression was witnessed in the two years following the preaching tour of Rev. George Whitefield in 1740. This spiritual quickening is known as the "Great Awakening," and undoubtedly added many to the membership of the churches. It was marked, however, by much excitement, and was followed by a period of spiritual decline lasting through the troubled years of public conflict and debate which ended with the adoption of the Constitution of the United States. It resulted in serious controversy in the churches of New England as to its merits, those who opposed it as on the whole harmful being called "Old Lights" while those who favored it were nicknamed "New Lights." In the teachings of Jonathan Edwards (1703–58) a theological movement of importance in American religious history began; and the modified Calvinism of the Edwardean school was further developed by Joseph Bellamy (1719–90), Samuel Hopkins (1721–1803), the younger Jonathan Edwards (1745–1801), Timothy Dwight (1752–1817), and Nathanael Emmons (1745–1840) into a distinctive New England theology. In eastern Massachusetts, on the other hand a "liberal" school arose before the American Revolution, which grew slowly and was made clearly evident in the Unitarian separation of the early years of the 19th century — a separation that had its most conspicuous manifestation in the adhesion of Harvard College to the "liberal" side in 1805, though the full significance of the division was not apparent until 10 years later.

With the decade beginning in 1791, the Congregational churches of New England experienced a series of revivals which were repeated at intervals until 1858. Under these impulses not only was the membership of the churches much enlarged, but a rapid development of agencies for missionary evangelization and religious education took place. The churches of Connecticut, which had already done home missionary work in Vermont and New York for more than 20 years, organized their "General Association" in 1798 as the "Missionary Society of Connecticut." A missionary society

was formed in Massachusetts in 1799. In 1801 the "New Hampshire Missionary Society" was inaugurated, and in 1807 a similar organization was effected in Vermont. These societies were chiefly engaged in home missions in the then Western States and Territories, though some work was done by them among the Indians; but in 1810, the "American Board of Commissioners for Foreign Missions" came into being and enlisted the activities of the Congregational churches in evangelization abroad. This society was followed, in 1815, by the formation of what is now known as the "Congregational Education Society" for assisting ministerial candidates and institutions of learning. In 1826 an "American Home Missionary Society," now known as the "Congregational Home Missionary Society" was organized to undertake home missionary work. These were followed later by the formation of the "American Missionary Association," in 1846, for labor, especially, among the negroes and Indians of the United States — a society which has done a large missionary and educational work in the South since the Civil War. In 1853, the "Congregational Church Building Society" came into being, under the title of the "American Congregational Union" — an organization the work of which is sufficiently described by its more recent name. All these societies still exist and serve as agencies for the missionary activities of the Congregational churches of the United States. By the action of the "National Council" of 1913, ratified by these societies, the voting membership of the council are voting members of each of these "national" societies, which are then brought into direct relations to the churches. A considerable consolidation of these societies has been planned but the details have not been fully worked out.

Contemporary with this awakening of missionary activity and immediately consequent upon the passage of Harvard University to the "liberal" side occurred an extensive development of theological education, beginning with the opening of Andover Theological Seminary in 1808. Bangor Theological Seminary was founded in 1816; and, in 1822, the theological department of Yale University was organized. Local disputes in Connecticut growing out of the modified type of Edwardean theology presented by Prof. Nathaniel W. Taylor of Yale led to the organization in 1834 of what is now known as "Hartford Theological Seminary." The theological department of Oberlin College came into existence in 1835, and the westward growth of the denomination brought about the opening of "Chicago Theological Seminary" in 1858, and of "Pacific Theological Seminary," now at Berkeley, Cal., in 1869. The latest school for ministerial training is that opened at Atlanta, Ga., in 1901. These eight theological seminaries are the principal agencies for the training of the ministry of the Congregational churches of the United States. The Congregationalists of Canada have a seat of ministerial education in the "Congregational College of Canada," established in 1830, and now affiliated with McGill University at Montreal. In Great Britain no less than 11 Congregational "colleges" do a work similar to that of the "theological seminaries" on this side of the Atlantic.

To the close of the 18th century the Congregational churches of the United States were practically confined to New England; and, in the subsequent westward extension of New England emigration, Congregationalism and Presbyterianism long worked together in the formation of churches in the newer States under the so-called "Plan of Union" of 1801. This "Plan" was repudiated by the "Old School" wing of the Presbyterian body in 1837, and by the Congregational churches, through the "Albany Convention," in 1852. Congregationalism has now extended in force to those parts of the United States, especially, which have been settled through New England emigration. Throughout the latter half of the 19th century, the Congregational churches of the United States have felt an increasing denominational consciousness, which has found its expression, among other ways, in the gathering of bodies representative of these churches as a whole. A "Convention" met at Albany in 1852, a "National Council" at Boston in 1865, and since 1871 a "National Council" has met every three years. In 1913, by a new constitution then adopted, its sessions became biennial. Besides this "National Council" in which delegates of the churches of the United States are regularly assembled, the churches of each State are represented in an annual "Conference"; and the churches of smaller districts, usually counties, meet in more local "Associations." None of these bodies are in any sense courts of discipline, but they gather for deliberation, consultation and joint action by committees, or otherwise, in matters of common concern.

Each Congregational church is a self-governing body, capable of choosing its own officers, expressing its creed in such forms as seem best to it, determining the conditions for the admission of its members, and ordering its public worship as it deems most fitting. But while a Congregational church is a self-governing democracy, Congregationalism, always in the United States, and increasingly in Great Britain, has insisted that its churches are knit together in sisterly fellowship, and owe, therefore, to one another, advice in all matters of importance, discipline in evident error and mutual helpfulness. Hence in questions of serious ecclesiastical concern such as the settlement or dismissal of a pastor, the management of a case of discipline which the local church finds it impossible to handle, the organization of a new church, and the like, Congregational usage in the United States, though not in Great Britain, requires the summons of an "advisory council" composed of a variable number of churches, chiefly from the vicinity, which are represented in the council by their pastors and a delegate each. These councils oftentimes also include a few individuals summoned by name as experts in the matter under consideration. By such an "advisory council," met for the particular occasion, advice is given; and, though this advice is not obligatory, it is seldom that the opinion of such a council is disregarded.

Membership in a Congregational church is conditioned on the vote of the local church itself, in view of the candidate's profession of faith in Christ, evident determination to live a Christian life and acceptance of the covenant

obligations of Christian service in connection with the local company of Christian disciples of which he desires to become a member. While all matters of concern in a local congregation are determined, ultimately, by the votes of the membership, Congregational churches transact their business chiefly through the use of committees, and a standing «prudential committee» to assist the pastor and deacons is appointed in most churches of numerous membership.

But while each church is thus free to establish such a test of the faith of candidates for its membership as it deems proper, Congregationalists in representative assemblies or in a more informal way have always been ready to testify to their faith of public creed declarations. Examples of such witness-bearing have been the approval of the doctrinal portion of the Westminster Confession by the New England churches by the Cambridge Synod in 1648; the modification of that confession by delegates of the English churches gathered at the «Savoy,» London, in 1658, and its publication as the «Savoy Declaration»; and the substantial confirmation of this «Declaration» by the churches of Massachusetts in 1680, and of Connecticut in 1708. Later examples of the same readiness of Congregationalists to witness to their beliefs is seen in the «Principles of Religion» adopted by the «Congregational Union of England and Wales» in 1833; the «Burial Hill Declaration» approved by the «National Council» of the United States in 1865; the «Commission Creed» issued by a committee of the same American body in 1883 and the brief statement of faith and polity prefixed to the constitution adopted by the National Council which met at Kansas City in 1913. All of these statements have been regarded, however, as testimonies rather than as tests of ministerial fitness or church-fellowship.

Aside from its representation in the United States, Congregationalism is strongly entrenched in Great Britain, where its adherents are often known by the name «Independents.» The churches of this order in Great Britain are grouped together in county and district «Unions» and «Associations» and are represented in the «Congregational Union of England and Wales» and the «Congregational Union of Scotland.» In general, however, the Congregational churches of Great Britain have emphasized mutual accountability and organization into representative bodies much less than those of the United States. Congregationalism is creditably represented in the Dominion of Canada and in Austria, as well as on missionary soil, where the two extensive Congregational missionary agencies, the «American Board,» and the «London Missionary Society,» have labored. An «International Council,» representative of all lands in which Congregationalism has found a home, held its first session at London in 1891, its second at Boston in 1899 and its third at Edinburgh in 1908.

Congregationalists in foreign countries numbered 1,378,447 on 1 Jan. 1928, (includes United Church of Canada) of whom by far the larger number are in the British Isles. There are:

In England and Wales	438,080
" Scotland	38,159
" South Africa	32,191
" Japan	49,410

and the rest in other countries.

The Congregationalists of the United States reckoned their communicants (including those of the Christian Church now united with them) at 1,048,281, with 6,558 churches and 6,744 ministers on 1 Jan. 1931. The enrolment in Congregational Sunday-schools was 785,431. Contributions for the maintenance of the churches in the United States in 1928 totaled $21,713,328 and contributions for benevolences, $4,166,952.

In 1929 conferences and negotiations resulted in an unanimous vote in the general conventions of the Congregational Church and the Christian Church for an organic union of the two bodies. For legal reasons their separate identities were to be maintained for some time. On 1 Jan. 1931 the departments of home missions, foreign missions and Christian education of the two churches were combined under a single management, the directing officiary being made up of representatives from both churches. State organizations and local churches have been combined. The First General Council of Congregational and Christian Churches was held in Seattle, Wash., beginning 24 June 1931, to effect a more complete cohesion. Delegates were selected on a uniform basis of representation in both denominations. The Christian Church brought to the Congregational 110,326 members with 1,283 church organizations; a ministry numbering 1,047; 1,324 Sunday-schools; 801 Christian Endeavor societies and 307 women's societies.

While the title «Congregational» designates a particular fellowship of churches, or religious denomination, in the United States and Great Britain, the Congregational form of church organization, especially in its aspect of the self-government of the local congregation, is that of many other religious bodies, notably of the Baptists, the Christians, the Unitarians and of certain branches of the Adventists, and Lutherans.

Late Professor of Church History, Yale University.
(Revised)

CONGREGATIONS, Religious, communities or orders, bound together by a common rule either without vows or with solemn vows. In France the name is so used as to include associations or confraternities of the laity. A group of monasteries is sometimes called a Congregation, when they unite themselves closely by ties of government and discipline and

by similarity of rule. The Cassinese congregations of Benedictines and the Congregation of Cluny are examples. The Roman Catholic Church uses the term to designate a committee of cardinals entrusted with a department of Church affairs, such as the "Congregation of Rites," which regulates the festivals and offices of new saints.

CONGREGATIONS, Sacred. A Congregation is a committee or college under the superintendence of the Pope for the transaction of the business of the Church. Cardinals resident in Rome make up in large part the membership of the congregations, and one of them is usually president or prefect.

It is evident that the Pope cannot provide personally for all the needs of the universal church. From early times the popes made use of counsellors and assistants. Pius IV and especially Sixtus V (1585–90) created the Roman congregations upon which devolved the burden of supervising the ordinary affairs of the universal church. Sixtus V instituted 15 congregations; but in the course of time some were overburdened, while others lost their importance. This led Pius X to issue a constitution *Sapienti Consilio* June 1908, in which he reorganized the whole Curia, and defined the duties and powers of each Congregation. Benedict XV made further progress in reorganization when in March 1917 he suppressed the Congregation of the Index, assigning its functions to the Holy Office, and transferred the Department of Indulgences from the Holy Office to the S. Penitentiary, and increased the scope of the Congregation of Studies. The constitution and function of each Congregation are now determined by the provisions of the Code of Canon Law—Lib. II; Pars. I; Tit. VII; Cap. IV; Canons 246–257. The Code prescribes that each Congregation shall be composed of a number of cardinals appointed by the Pope, and of minor officials necessary for the work of the Congregation. Each Congregation has a Prefect. In the case of the Holy Office, the Consistorial Congregation and the Congregation of the Oriental Church, the Pope is the Prefect, and he is represented in the meetings by a Cardinal Secretary. In all other cases there is a Cardinal Prefect. While the power of each Congregation is limited by law to the matter assigned to it, these matters may affect any part of the world, because the Congregations attend to the business of the universal church, and they make or at least interpret laws for the whole Catholic world. The form of procedure varies according to the nature of the Congregation and the matter submitted. No extraordinary matter may be dealt with, or extraordinary decision reached, without special permission of the Pope. But routine matters are settled by the Prefect or Secretary.

The decisions are usually given in simplest form. "Affirmative" or "Negative" is the usual answer; though at times an advice or "mens" is added. The decisions too are practically final, since the only recourse is a petition for another hearing.

The Sacred Congregations are:

1. *The Congregation of the Holy Office.*—This Congregation is a later development of the Roman Inquisition. Acting on the principle that the Church is commissioned by Christ to "preach the Gospel to every creature" (Mark xvi, 15) the supreme authority must take cognizance of what is being taught in the name of the Church, and protect the members of the Church from error, no matter what the source of the error may be. Sixtus V committed this duty to the Congregation mentioned. The duty of examination, revision and condemnation of books belonged originally to the Holy Office, but it was later given to a special Congregation, viz., the Congregation of the Index. It is now again attached to the Holy Office. The Holy Father is the Prefect of the Congregation of the Holy Office. The Congregation has general supervision of all matters of faith and morals, and judges of these matters both in the first instance and on appeal. To it are committed also certain matrimonial cases, namely, the Pauline Privilege and so-called "mixed marriages," i.e., marriage of a Catholic to a non-Catholic. The Holy Office is also the censor of books; it issues the Index, or list of prohibited books. It may call for correction of errors by the author, or forbid the publication of a book, or give warning of erroneous teaching in a book already published. This Congregation alone is competent to decide questions regarding the Eucharistic fast of priests celebrating mass.

2. *The Consistorial Congregation.*—We must not confuse "Consistory" and "Consistorial Congregation." A Consistory is a meeting of the College of Cardinals present in Rome, and assembled before the Pope, for consultation and for the decision of very important ecclesiastical affairs. This meeting of the Pope and the cardinals may be secret or public. The Public Consistory is restricted to certain solemn functions such as the conferring of the Red Hat on newly created cardinals, and is usually the occasion of an "allocution" or speech by the Holy Father, in which he may wish to make clear the policy of the Holy See on public questions. The Secret Consistory is the private meeting of the Pope and the cardinals at which important matters may be decided. The matters discussed depend on the wishes of the Pope, and on previous action of the Consistorial Congregation which prepares the agenda for the Consistory. The Consistorial Congregation is composed of the Pope as Prefect, and certain cardinals ex officio, namely, the Secretary of State, Secretary of the Holy Office and the Prefect of the Congregation of Studies. The Assessor of the Holy Office, the Secretary for Extraordinary Ecclesiastical Affairs and the Secretary of the Congregation of Studies are Consultors of this Congregation. The Consistorial Congregation has assumed new importance since the reorganization of the Curia by Pius X. On it devolves not only the preparation of the agenda for the Consistories, but also, in places not subject to the Propaganda, the erection of dioceses and provinces and their division; the proposal of bishops, apostolic administrators, episcopal coadjutors and auxiliaries. The Consistorial Congregation receives the report of bishops when they go to Rome for ad limina visits. In a word to it belongs all that pertains to the constitution, preservation and state of the various dioceses throughout the world, with the exception that missionary countries remain subject to the Propaganda. As the United States is no longer a missionary country it is the Consistorial Congregation that decides these important matters for this country.

3. *S. Congregation of the Sacraments.*— This Congregation is entirely new. To it is subject whatever concerns the seven sacraments. Certain matrimonial cases are reserved to the Holy Office, and the ceremonial to be observed in the administration and reception of the sacraments can be decided only by the Congregation of Rites. Whenever there is need of dispensation from impediments of a public character appeal must be made to the Congregation of the Sacraments. To this Congregation belongs also the decision of many questions concerning the Mass and the preservation of the Holy Eucharist, and all questions concerning the validity of Ordination and the obligations imposed on those who receive the Major Orders.

4. *The S. Congregation of the Council.*— This Congregation was charged originally with the interpretation and execution of the reform decrees of the Council of Trent. It was instituted by Pius IV in 1564; Pius V and Sixtus V enlarged its faculties. The importance of this Congregation has diminished since the institution of the Congregation of the Sacraments; but it still administers many matters pertaining to the secular clergy, to confraternities, pious bequests, Mass stipends, ecclesiastical property and similar questions. Besides it grants permission to hold councils and examines the documents and decrees of councils which must be submitted for approval. Its officers are a Cardinal Prefect, a Secretary, sub-secretary, consultors and minor officials.

5. *The S. Congregation of Religious.*— This Congregation was formerly part of the Congregation of Bishops and Regulars, which at one time had great authority. It is now an independent Congregation, with its own Prefect and other officials. To this Congregation are referred all questions concerning the government, discipline, studies, property and privileges of religious and of all who live the life of religious. Hence all orders of men or of women, and the so-called third orders, are subject to the supervision of this Congregation. It decides also questions of entrance, novitiate, studies, discipline, etc., of the religious orders; and it is competent to grant dispensations in the same matters.

6. *The S. Congregation of the Propaganda (de propaganda Fide).*— Since it is the mission of the Church «to teach all nations» (Matt. xxviii, 19) she must make constant effort to bring the Gospel to the unbeliever. But in a well-ordered society this work must be carried on in a regular and orderly manner. In those parts of the world where the hierarchy is established, i.e., where the government of the Church is fully organized, this work is regulated by archbishops and bishops, under the Holy See. In mission countries, however, we have need of other government. In order to insure an orderly and stable procedure in missionary matters Gregory XV in 1622 founded the Congregation de Propaganda Fide, commonly called the Propaganda. The jurisdiction therefore of this Congregation is limited to «missionary countries.» Of all the congregations, the Propaganda was formerly the most interesting to English-speaking peoples, since the government of the Church in these countries was subject to this Congregation. Now however the United States, England, Ireland, Scotland and Canada are withdrawn from the Propaganda and placed under the hierarchy or common government of the Church. The Propaganda still regulates ecclesiastical affairs in many parts of the world. In such places it not only provides for the preaching of the Gospel, but regulates all things «necessary and opportune» to the work of the Church. It cannot however infringe on the rights of other congregations in matters peculiarly subject to them. The Congregation is presided over by a cardinal called the Prefect-General. There are also a Prefect of Economy (who supervises temporalities) and a Protonotary Apostolic (for the records). The Congregation supervises all societies of ecclesiastics and seminaries founded exclusively for foreign missions, and has besides a college of its own, called «Collegium Urbanum,» attached to the palace of the Congregation. This college was founded by Urban VIII to prepare young men for missionary labors.

7. *The Congregation of Sacred Rites.*— Man naturally expresses his worship of God in an external manner. The rites and ceremonies which the Church makes use of in the worship of God are an external expression of the faith. To see that the proper rites are observed, to make liturgical laws, to enforce and interpret them, to issue or approve of liturgical books is the duty of the Congregation of Rites. Hence the ceremonies of the celebration of Mass and the administration of the sacraments in the Latin Church, and the solution of all questions pertaining to them, depend on this Congregation. The Congregation of Rites also prepares the causes of Beatification and Canonization, and supervises the use of sacred relics. The number of cardinals assigned to the Congregation of Rites depends on the reigning Pontiff. There is always a Prefect, a Secretary, the Promoter of the Faith, a Chancellor, a Hymnographer who arranges and corrects the offices of the saints and other liturgical prayers, and a number of consultors.

8. *The S. Ceremonial Congregation.*— This Congregation is entrusted with the direction of ceremonies to be observed in the Papal Chapel and Court, and of the sacred functions which cardinals perform outside of the Papal Chapel. It also decides questions of precedence among cardinals and among ambassadors accredited to the Holy See.

9. *The S. Congregation for Extraordinary Ecclesiastical Affairs.*— This Congregation deals with Church government in matters that are arranged according to Concordat with some civil government. Hence it is entrusted with the erection and division of dioceses and with the filling of vacant sees when these are subject to Concordat. Special questions may be referred to it by the Pontiff through the Secretary of State.

10. *The S. Congregation of Studies in Seminaries and Universities.*— This Congregation watches over the government, discipline, temporal administration and course of studies in ecclesiastical seminaries, except those subject to the Propaganda. It also moderates discipline and course of studies in Catholic universities, examines and approves new institutions, grants the faculty for giving degrees and determines the requirements for them, and may itself confer degrees on anyone distinguished for learn-

ing. The Cardinal Secretary of the Consistorial Congregation is ex officio a member, and the Assessor of the same Congregation is ex officio a Consultor of Studies. The beginnings of the Congregation of Studies may be found in the Bull of Sixtus V. But the learned Leo XIII is generally considered to have perfected its institution, as he extended its authority to all Catholic universities of the world. The Congregation of Seminaries and Universities, founded in 1915, was distinct from the Congregation of Studies. Now however both form one Congregation under the fuller title, and this Congregation has jurisdiction over both seminaries and universities, and watches over discipline as well as studies.

11. *The S. Congregation for the Oriental Church.*— This was formerly part of the Congregation of the Propaganda, but is now an independent Congregation. To it belong all affairs which touch persons, discipline or rites of the Oriental Churches, even if these concern Latins also. So that this single Congregation has the same powers for the Oriental Churches that all the other congregations have for the Latin Church, without however infringing on the authority of the Holy Office which is in its own sphere truly of universal jurisdiction. The Pope is the Prefect of the Congregation of the Oriental Church. The Congregation settles matters administratively only. Judiciary questions are referred to tribunals designated by the same Congregation.

Besides the foregoing the Sovereign Pontiff makes use of commissions for the performance of certain duties. See CURIA ROMANA and consult Ferraris, 'Congregationes'; Wernz, 'Jus Decretalium' (Vol. II, p. 11); Ojetti, 'Synopsis Rerum Moralium et Juris Pontificii'; Father Augustine, 'A Commentary on Canon Law' (Vol. II, St. Louis 1918); Constitution, 'Sapienti Consilio' (1908); 'Codex Juris Canonici' (Canons 246 et seq.).

JOHN F. TURNER, D.D.,
St. Joseph's Seminary, Dunwoodie, N. Y.

CONGRESS (Lat. «coming together,» «meeting»), a meeting of rulers or representatives of several states, to adjust disputes between different governments. It is necessary to distinguish the meeting in which preliminaries are settled, from the principal congress, which is to bring the affair in question to a decision. The plenipotentiaries when they meet, after mutual greetings, appoint, in a preliminary conference, the day on which the congress is to be opened, and determine the manner in which business is to be transacted, the forms of negotiation, the order of precedence among the different powers and the time of session. The congress opens by the exchange and perusal of credentials among the plenipotentiaries, which, in case the negotiating parties have referred to the arbitration of a mediator, are given to him. The envoys of the contending powers then carry on their negotiations directly with each other, or by the intervention of a mediator, either in a common hall or in their own residences by turns, or, if there is a mediator, in his residence. These negotiations are continued either by writing or by verbal communication, until the commissioners agree upon a treaty, or until one of the powers dissolves the congress by recalling its minister. Such meetings of the representatives of different countries are sometimes called conferences. The nominal difference between a conference and a congress is this, that the representatives of the different countries at the former are the ordinary ambassadors of the respective countries at the court at which the conference is held, while the representatives at the latter are specially deputed for the purpose. Among congresses of the 19th century the chief are the Congress of Vienna, 1815; of Paris 1856; of Berlin 1878; The Pan-American Congress at Washington, D. C. (1888–90).

CONGRESS, Continental. The first recognition of a solidarity of interests among the English colonies in America, and attempts at joint action against a common foe, were made in 1690, by Jacob Leisler, revolutionary dictator of New York; and his efforts were stimulated by the fact that New York bore the first brunt of Canadian invasion, and needed help. He invited the other colonies to send delegates to New York and contribute men and money for a counter-invasion; but none farther south than Maryland responded. A much more comprehensive plan was devised by Franklin in 1754 (see ALBANY CONGRESS), but fell through. In 1765, on occasion of the Stamp Act (q.v.), a colonial congress from all the North except New Hampshire, and only South Carolina of the South below Maryland, met at New York 7–25 October, but took no action except to petition Parliament. In 1773, when the Revolution was impending, Franklin renewed his former suggestion in a letter to the assembly of Massachusetts, whose agent in London he was, but still nothing was done.

The next year, however, on receiving news of the Boston Port Bill, Virginia proposed to the other colonies a Continental Congress in the fullest sense; that is, including Canada, for it was not doubted that this recently subjugated province would gladly join in a revolt against its conqueror. Massachusetts responded 7 June, others followed, and the first real American Congress met in Philadelphia, 5 Sept. 1774, sitting till 26 October. Canada, however, was not represented; nor was Georgia, though it shared in all succeeding Congresses. The instructions to the delegates did not contemplate separation or forcible resistance, but only the proposal of measures to «restore harmony» with Great Britain; and the Congress merely drafted addresses to the king and the people of that country, to the Canadians, and to their own constituents, and recommended non-importation and non-exportation agreements, and the forcible resistance to any forcible attempt to carry out the Parliament's taxation measures. It also advised the immediate election of delegates to a fresh Congress in Philadelphia 10 May 1775; which was carried out by various bodies — legislative assemblies in some cases, popular conventions or committees of safety (q.v.) in others. None of these had any legal power to act for this purpose, and the title of all alike was the will of the *force majeure* of the people; for the loyalist section had equal right to oppose the elections, and it was tacit acceptance of superior fighting force that gave the title. The fact that this Congress was considered necessary at all, and was to have power to organize combined resistance to Great Britain, would be conclusive evidence that the

leaders of public opinion had determined on independence unless highly improbable concessions were made, were it not for the extreme reluctance the Congress displayed in declaring it, only doing so under irresistible urgency from public opinion. A parallel case is the memory of the hopes of accommodation and conciliation by Union leaders not only in 1860–61, but all through the Civil War. The frequent charge of hypocrisy against the Revolutionary leaders involves one against all the patriotic statesmen of the decade before 1860.

As soon as war was actually proclaimed by Great Britain the second Congress assumed the fullest powers of sovereignty; much greater than those of the British Parliament, for it combined the powers of that body, with those of the king, being itself both executive and legislative head of the nation. It raised military and naval forces and directed belligerent operations with them, authorized privateering, contracted treaty alliances, issued national currency, etc., in both capacities. This was by no usurped power, but by the urgency of the people, who were far more anxious to have it take the powers than it was to exercise them. The provincial congresses appealed to it for authorization and the people urged it to more energetic action. Its crowning act was the Declaration of Independence; its business from 12 July to 20 August the debating of the scheme of government it had drafted (see UNITED STATES —ARTICLES OF CONFEDERATION). It sat till 12 Dec. 1776.

The session of 20 Dec. 1776 has been hesitantly called the third Continental Congress; for the delegates were selected entirely by the State legislatures, and the body as a whole had a title more definite and regular, though not in reality more legal.

A history of the Congress is a history of the country during its lifetime; but some of its migrations are significant of military reverses and recoveries. From 20 Dec. 1776 to 4 March 1777 it sat at Baltimore; 4 March to 18 Sept. 1777, at Philadelphia; 27 Sept. 1777, at Lancaster, Pa.; 30 Sept. 1777 to 27 June 1778, at York, Pa.; 2 July 1778 to 21 June 1783, at Philadelphia. But before this it had ceased to be the Continental Congress, and had become the Congress of the Confederation, on 2 March 1781, after the ratification of the Articles by Maryland. Consult Histories of the United States by Bancroft, Hildreth, Schouler, Von Holst, etc.

CONGRESS OF INDUSTRIAL ORGANIZATIONS (C. I. O.). One of the two great labor organizations of the United States, founded in 1935 by the presidents of eight international unions of the American Federation of Labor as the Committee for Industrial Organization. In August 1936, the executive council of the A. F. of L. suspended the C. I. O. unions, and the suspension went into effect in September following. John L. Lewis, president of the United Mine Workers of America, was the moving spirit in the organization of the C. I. O., and its president until he retired in November 1940. At a convention in Pittsburgh in November 1938, the C. I. O. organized on a permanent basis, changed its name to Congress of Industrial Organizations, and adopted a constitution, asserting its objects as: 1. To bring about the effective organization of the working men and women of America regardless of race, creed, color or nationality and to unite them for common action into labor unions for their mutual aid and protection; 2. To extend the benefits of collective bargaining and to secure for the workers means to establish peaceful relations with their employers, by forming labor unions capable of dealing with modern aggregates of industry and finance; 3. To maintain determined adherence to obligations and responsibilities under collective bargaining and wage agreements; 4. To secure legislation safeguarding the economic security and social welfare of the workers of America to protect and extend our democratic institutions and civil rights and liberties, and thus to perpetuate the cherished traditions of our democracy. In 1940 it reported a membership of approximately 4,000,000, in 42 affiliated national and international unions and organizing committees, and 419 local industrial unions. In addition, it had affiliated to it 225 state, city, county, and district industrial union councils.

CONGRESS, The Library of, at Washington, D. C., is a part of the legislative establishment of the federal government. Founded in 1800, to provide «such books as may be necessary for the use of Congress,» it was for many years quartered in the Capitol. When, on 24 Aug. 1814, an invading British army fired the public buildings, the collections of the library were completely destroyed, but the Congress promptly re-established them by purchasing the distinguished private library of Thomas Jefferson. In 1851, another fire wiped out more than half of the collections, but since that time their growth has not been interrupted. In 1866, the library of the Smithsonian Institution was, by law, transferred to the Library of Congress, and a year later the Peter Force Collection of Americana was purchased by the enactment of a special appropriation of $100,000. At the same time a system of international exchange was organized. The entire copyright business was brought under the direction of the Librarian of Congress in 1870, and new effect was given the law requiring the deposit of copies of all publications in the Library of Congress as a condition precedent to registration. It was not until 1886, however, that funds were provided for a building of its own, and not until 1897 that the monumental structure on the square east of the Capitol plaza was completed. This made possible for the first time the development of adequate bibliographical apparatus, the differentiation of materials, and the establishment of departments. An act of Congress approved 3 March 1925, created the Library of Congress Trust Fund Board, which is authorized to accept endowments and to receive gifts of money for immediate disbursement. In 1939, an annex, made necessary by the growth of the collections and the extension of the library's services, was opened to the public. The total cost of the two buildings to date has been $18,470,000, and together they provide nearly 36 acres of floor space, 414 miles of bookshelves and 20 reading rooms, as well as 266 study rooms and 225 reserved desks for the use of scholars conducting research on the premises.

On 1 March 1941, the library contained about 6,253,800 books and pamphlets. It houses the largest and most important body of manuscript materials for American history in existence. The collections include papers of most of the Presi-

dents from Washington to Coolidge. Conspicuous exceptions are the papers of the Adamses, Buchanan, Hayes, and Harding, located elsewhere. Important manuscript collections of American statesmen are those of Benjamin Franklin, Robert Morris (including the records of his service as Superintendent of Finance), Alexander Hamilton, Charles Cotesworth and Thomas Pinckney, Henry Clay, Daniel Webster, J. J. Crittenden, Salmon P. Chase, Gideon Welles (including the famous diary), Edwin M. Stanton, John Sherman, Hamilton Fish, and Richard Olney. Collections ranging from Nathanael Greene to Tasker H. Bliss, and from John Paul Jones to George Dewey, illustrate the military and naval history of the United States. Original materials are supplemented by some three million folios of reproductions of materials in European repositories bearing upon American history. Noteworthy individual manuscripts are the original Declaration of Independence and the Constitution of the United States, displayed in a shrine visited by thousands of Americans daily; and Lincoln's first and second drafts of the Gettysburg Address. The Music Division has the largest collection in America and one of the finest in existence. In 1940 the musical items totaled 1,399,357. They include holographs of master composers, thousands of orchestral scores, vast holdings in dramatic music and Americana, and a huge collection of American folksongs recorded on disks. The latest development is the Recording Laboratory. The division also sponsors numerous chamber music concerts. The Rare Book Collection has more than 125,000 items in its air-conditioned vaults. The books cover the entire range of bookmaking from illuminated medieval manuscripts through the beginning of printing and bookmaking up to the fine printing that is being done today. The Incunabula Collection now numbers nearly 5,000 volumes including the great Gutenberg Bible printed on vellum and known as the St. Blasius-St. Paul copy from the Benedictine Monastery of St. Paul in Carinthia. The collection of early printing in Europe and America is also remarkable. These works are supplemented by large collections of early newspapers, almanacs, broadsides, and documents. The Thomas Jefferson library, the nucleus of the collections of the library, is housed in the Rare Book Room. In the field of Orientalia the Chinese collection, comprising about 225,000 volumes, is the largest outside China and Japan. It contains many early printed books and manuscripts and is especially rich in local histories, encyclopedias, works on agriculture and medicine, and the collected writings of individual authors. The Japanese collection contains about 40,000 volumes. In addition, there are works in Korean, Tibetan, Manchurian and Mongolian. The collections of Slavica, founded upon the purchase, in 1907, of the private library of Genadii Vasilevich Yudin, of Krasnoyarsk, Siberia, have grown to 168,850 pieces. There is a distinguished collection of Hebraica. The cartographic holdings comprise 1,441,719 maps and views and 12,521 atlases. Among the outstanding collections of the Division of Maps are the atlases of Ptolemy, Ortelius, Mercator, and Blaeu, and a great number of manuscripts and early printed maps of the United States. In the Division of Fine Arts are more than 500,000 prints of all sorts, including photographs and photomechanical reproductions, etchings, engravings, etc. Notable among its special collections received by gift, are the Gardiner Greene Hubbard collection of engravings, the Joseph and Elizabeth Robins Pennell collection of Whistleriana and Pennelliana, and the Alexander Wilson Drake Collection of American wood engravings. The Pictorial Archives of Early American Architecture are administered by this division. Here photographic negatives of early buildings are being assembled for purposes of historical and architectural study and for supplying prints where desired. To this the drawings and photographic negatives of the Historic American Buildings Survey have been added. The Division of Aeronautics contains the world's largest collection of the literature of its field, and it is believed to be virtually complete. The Hispanic Foundation, a center for the pursuit of studies in Spanish, Portuguese and Latin American culture has been established with the generous co-operation of the Hispanic Society. The Law Library of Congress, the only general legal research library maintained by the federal government, contains more than half a million volumes. The reference staff and facilities of the Library of Congress are available to members of the public, universities, learned societies and other libraries requiring services which the library staff is equipped to give and which can be given without interference with services to the Congress and other agencies of the federal government.

DAVID C. MEARNS,
Superintendent of the Reading Rooms, Library of Congress.

CONGRESS OF RELIGIONS or WORLD'S PARLIAMENT OF RELIGIONS. A congress held at the Columbian Exposition, Chicago, in 1893, in an attempt to bring together representatives of the great, historic religious creeds of the world. The Congress of Religions, which was what its name implies, was made up of representatives of the creeds of all the great countries of the world; and it treated of almost every aspect of religion. It was the outcome of many attempts to bring together the great religions of the world. The idea of a union of this kind had often appeared in Chinese fiction and poetry; and both China and Japan had led the way in religious toleration by allowing various creeds to flourish side by side in their respective territories hundreds of years before religious toleration was thought of in Europe. More than three centuries ago John Comenius, the great religious thinker and reformer, had suggested such an idea. Almost half a century ago the Free Religious Association of Boston advocated the idea of a congress of the various religions of the world with a view to making a scientific study of religious thought, origin and growth. In 254 B.C. the Buddhist Emperor of India, Asoka, called a congress of all the religions of the East, and more especially those of India, at Palateputra, now Patna; and he actually gathered the brightest minds of the East in religious circles in the congress, which was a pronounced success. So the religious centers of India, owing to their comparative liberalism, were ready to respond to the call issued in June 1891 for a Congress of Religions to be held in Chicago in connection with the World's Fair in 1892. The exposition was unavoidably postponed until the fol-

lowing year and with it the meeting of the Congress of Religions. This was fortunate for the latter as it gave the organizers much more time in which to reach the leaders of religious thought throughout the world. The World's Parliament of Religions, as the congress was ultimately named, set for its aim a wide and varied program which included the bringing together into a congress of leading representatives of the great historic religions of the world; the showing of the important truths held by various religions; the promoting of the spirit of human brotherhood among religious men of diverse faiths; the setting forth of the important distinctive truths held and taught by each religion and by the various branches of Christianity. It aimed to indicate the impregnable foundations of theism and the reasons for man's faith in immortality; the spiritual and other effects of the various religions upon literature, art, commerce, government and domestic and social life. The Congress was asked to consider what light each religion has afforded or may afford to other religions; the present condition and outlook of religions among the leading nations of the world and the light religion has thrown upon the great problems of the present age, such as temperance, labor, education, poverty, wealth. The promoters expressed their hope of eventually bringing about permanent international peace by bringing the nations of the earth into a more friendly fellowship. Consult 'World's Parliament of Religions,' a collection of the addresses made at the congress and an account of the proceedings of the same.

CONGRESS OF THE UNITED STATES. The legislative branch of the Federal government of the United States. The discussion of this body falls naturally into three parts: (1) The constitutional mandates concerning it; (2) its own rules and usages; (3) its practical functions as developed by historical evolution.

1. By the first article of the Constitution, the legislative power of the country, so far as granted at all, is «vested in a Congress of the United States, which shall consist of a Senate and House of Representatives.»

The Senate must consist of two senators from each State (thus equalizing the power of the States to safeguard their own interests), elected by the State legislatures for six years; the terms so arranged that one-third are vacated every two years, making it a continuing body. Each legislature fills any vacancy in its State delegation caused by death or resignation, but if one occurs while it is not in session, the governnor of the State may fill it pro tem. till the legislature meets. A senator must be 30 years old, nine years a citizen and an inhabitant of the State which elects him; but the legal definition of residence is impliedly left to the State. The president of the Senate is the Vice-President of the United States, who has only a casting vote; but in his absence, or on his accession to the presidency, it shall choose a president pro tem. All impeachment trials are its prerogative, to be decided by a two-thirds vote; if the President is impeached, the chief justice presides; it can inflict no punishment but removal from and disqualification for office. No treaties are valid without the consent of two-thirds of the Senate; nor any appointment to office by the President without the consent of a majority of it, unless Congress takes away this power from the senatorial half of itself, which it is not likely to do.

The House must consist of members chosen for two years by popular election, so that each House is a new body; the voters to be the same who choose the most popular branch of each legislature; each member must be 25 years old, seven years a citizen, and an inhabitant of the State. The number from each State must be graded by population, determined by a decennial national census (in the body of the Constitution, three-fifths of the slaves are to be counted in, a provision made obsolete by the Thirteenth Amendment). These representatives must not exceed one to 30,000 inhabitants — which would allow a maximum of about 4,500 at present, in place of the actual 435. The members receive an annual salary, determined by Congress, the amount of which at present is $10,000. In case of vacancy, the State executive is to issue a writ of election to fill it. The House chooses its own speaker who receives a salary of $15,000. And lastly, it has the sole power of presenting the impeachments which the Senate has the sole power of trying.

The State legislatures were to fix the times, places and manner of electing members of either House, subject to the right of Congress to change anything but the place of electing senators, which was the legislative chamber until 1913, when the 17th Amendment to the Constitution, providing for the direct vote for senators by the people, was ratified and declared in force. But the numerous deadlocks and failures to elect, due to the two branches of the legislature being under different political control, and the minority House refusing to meet the other for an election, led to the law of 2 July 1866, prescribing a uniform rule for all States. Congress is to meet at least once a year; on the third day of January unless it orders otherwise. The President can convene a special session on «extraordinary occasions»; but he cannot adjourn or prorogue it except in case of disagreement between the Houses — a provision suggested, like so many others, by the quarrels of the English Parliaments with the kings. Each House is the judge of the qualifications of its own members. A majority of each constitutes a quorum; but a single member can adjourn from day to day, and can compel the attendance of enough absent members to make a quorum if the House will provide a rule for so doing. Each House makes its own rules of procedure, can punish members for disorderly behavior and two-thirds can expel a member. Each must keep a journal of its proceedings (see CENSURE, CONGRESSIONAL, for argument on the implications of this), and publish it, except such part as the House judges best to keep secret. One-fifth of the members present at any time may compel a yea and nay vote to be taken on any question and entered on the journal. Neither House during a session shall adjourn for more than three days or to any other place, without consent of the other. Members of both Houses shall be paid by the nation. They shall be exempt from arrest during the session and in journeys to and from, and from liability for any utterances in debate—a reminiscence of the burning need of such provision in older English history; not often invoked now, and still less

often for creditable reasons. No member shall be appointed to any office created or its pay increased during his term—again a souvenir of temporary political squabbles; and no officeholder shall be at the same time a member. Bills for raising revenue must originate in the House (originally a safeguard for the large states, against the small ones using their power in the Senate to throw the financial burdens on their richer neighbors); but the Senate can propose amendments. Bills vetoed by the president must be reconsidered by, and the objections entered in full on the journal of, the House where they originated; and a two thirds vote may pass it to the other House, a two thirds concurrent vote of which makes it a law. (The first Congress, on the question arising, decided this to mean two thirds of those present and voting, not of the whole membership.) Such votes must be yea and nay and entered on the journals. A bill not returned by the president within 10 days (Sundays excepted) becomes a law *ipso facto,* unless Congress adjourns meanwhile, when it lapses. No order, resolution or vote of the concurrent Houses is valid without the assent of the president, except one to adjourn.

The powers of Congress are generally those inherent in every sovereign assembly of the people; but there are two important restrictions. The president's veto (above) is a very real restraint on tyranny by a bare majority, perhaps not honestly obtained and always inviting dishonesty with such supreme power; and it retains full vitality, while the English royal veto has perished. Still more important is its confinement by the Constitution to the powers expressly granted: its laws are invalid if pronounced by the Supreme Court contrary to the Constitution, while a majority vote of the English Parliament could theoretically abolish the monarchy or hang the entire population. Too much is sometimes made of this, however. The "implied powers" of caring for the national welfare have been found in practice elastic enough for every claim of sovereignty. In a measure the Supreme Court is a creature of Congress, since the Constitution does not fix its membership, which can be and has been changed by Congress at various times and for various purposes, as in 1869. Some authorities hold that even if its decisions are defied (as under Jackson), it is powerless to enforce them. Hence it is very cautious about deciding "political" issues of burning intensity (see CHEROKEE NATION V. GEORGIA), except in the sense of the majority or opposing strong popular feeling. In a word, Congress is the ultimate sovereign. Its inhibitions by the Constitution reflect past history and the politics of the time curiously enough. It was not to prohibit the slave-trade before 1808, and not to grant titles of nobility—conversely, no one is to receive office, title or gift from any foreign potentate without its consent; it is not to suspend the habeas corpus except on account of rebellion or invasion, not to pass bills of attainder, not to lay export taxes, nor direct taxes except in proportion to population, not to give preferential duties between the states, or enforce clearances at ports outside a vessel's destined state. Not all of these things were needless fetters; and certainly the prohibition from drawing money except on regular appropriations, and the injunction to publish the disposition of the money drawn, was not one.

There being at present 48 states, the number of senators is 96. The number of representatives has never been determined by the constitutional provision, whose minimum was fixed when the country had but 2,500,000 or so of inhabitants. The maximum has been slowly enlarged at each census, each state retaining all it had, while the states with increased population have been given more members. The basis of apportionment under the census of 1940, however, was in relation to state populations; accordingly, some states lost members. The representations thus became: Alabama, 9; Arizona, 2; Arkansas, 7; California, 23; Colorado, 4; Connecticut, 6; Delaware, 1; Florida, 6; Georgia, 10; Idaho, 2; Illinois, 26; Indiana, 11; Iowa, 8; Kansas, 6; Kentucky, 9; Louisiana, 8; Maine, 3; Maryland, 6; Massachusetts, 14; Michigan, 17; Minnesota, 9; Mississippi, 7; Missouri, 13; Montana, 2; Nebraska, 4; Nevada, 1; New Hampshire, 2; New Jersey, 14; New Mexico, 2; New York, 45; North Carolina, 12; North Dakota, 2; Ohio, 23; Oklahoma, 8; Oregon, 4; Pennsylvania, 33; Rhode Island, 2; South Carolina, 6; South Dakota, 2; Tennessee, 10; Texas, 21; Utah, 2; Vermont, 1; Virginia, 9; Washington, 6; West Virginia, 6; Wisconsin, 10; Wyoming, 1—Total 435. Alaska and Hawaii are represented by one nonvoting delegate each; Puerto Rico and the Philippines by one nonvoting resident commissioner each.

2. Each house has its own system of rules, with vital differences. The most far-reaching is the previous question in the House and the absence of it in the Senate. The reasons for the difference are obvious: the great number of representatives, and the fact that most bills are first introduced there, would make business not merely difficult but impossible if everyone could talk at will to any length; the smaller numbers and lesser business of the Senate enable free debate to be retained. The House restricts speeches to an hour; the Senate has no restriction except that a member cannot speak over twice a day on the same question. Each system of course has its attendant possibility of evil: the suppression of needful public light on bills in the one case, "filibustering" and holding up of public business by a factious or interested minority in the other. The business of both houses is done by committees; neither will consider bills or memorials at once on presentation, except on suspension of the rules—which to be sure, during the latest days of a session, lets through vast numbers of undebated, unexamined and unknown bills. But by rule they must be referred to some standing committee, of which there are now 48 in the House and 33 in the Senate, besides some 29 congressional commissions and joint committees including standing committees. The functions of these committees are assigned by the rules; but as these lap over, two or three committees often contend vigorously for the possession of some one bill. In the Senate, these bills are presented in open session on the floor; in the House they are handed to the clerk indorsed with such reference or disposition as the presenting member wishes made. These committees are appointed in the House by the Speaker; in the Senate they are chosen by caucus of the majority party and elected by a single yea and

nay vote though the rules say by ballot «unless otherwise ordered.» In case of differences between the Houses which continually occur, they are harmonized by committees of conference, three senators and three representatives. The most steadily powerful of these committees, which can obtain the floor at any time, are those on Appropriations in each house, disbursing the money in the treasury, and on Privileges and Elections, deciding the right of every member to his seat; next to these, on revenue (Ways and Means in the House, Finance in the Senate), with enormous power to help or harm the great businesses of the country — many think too much — and on Printing, which of course is an immediate matter. Next in actual favor come, perhaps, those on Rivers and Harbors and on Pensions, branches of that on Appropriations which they involve; and when new States are to be admitted, on Territories. In formal dignity the Senate committees on Foreign Affairs, on the Judiciary and on Military and Naval Affairs, take high rank; so in the House do those on Rules, Foreign Affairs, Judiciary, Military Affairs and Naval Affairs; and of course special circumstances at any time may temporarily make any one of these, or almost any other committee, the centre of interest to which everything else must give way. In some respects most important of all except the Appropriations Committee are the special conference committees, which do an immense share of the actual legislation of the country: they compromise conflicting business and political interests, include or exclude bills, decide on appropriations, etc., and being usually appointed in the crowded closing days of a session, generally have their recommendations heeded.

3. The changes in congressional functions and relations, from the intent of the framers of the Constitution, come under three heads: (1) The position of Congress as a whole regarding the executive; (2) the position of the two houses regarding each other; (3) the position of the whole body regarding legislation.

(1) The Constitution attempted a total separation and absolute equality between the executive and legislative branches, the latter deciding on measures of public welfare and the former carrying them out. How far this would be desirable if perfectly accomplished — altogether forbidding one branch of the government to think and the other to act — might be questioned, but will not be argued here. At any rate, it was never remotely realized except when both were in deadly need of the same thing, or one was content to forego thinking. The ideal example of its best is probably the Lincoln administration, a strong executive and a strong Congress with the same essential purposes; of its worst, the Johnson administration, where the thoughts of the one and the acts of the other were at irreconcilable variance, and what the one most wished done was what the other was most set on not doing. More usually, one side or the other has been master. The extreme instance of executive mastery was the Jackson administration, where a resolute and aggressive leader, with a not too reflective popular majority behind him, got such legislation as he wished; of congressional mastery, each reader may prefer to choose his own instance. But there can be no question that the balance inclines more and more decisively to the congressional side. Of late years the results of attempted executive independence have been more picturesque than successful. The Senate, which has the confirmation of treaties and appointments, cannot be prevented from signifying in some form what treaties and appointments it will confirm; and the body which can grant or refuse money for public purposes can decide what those purposes shall be.

(2) The change of power between the Houses is not so dramatically obvious, but it is quite as notorious and is easily explicable. The Senate has some superiorities: its long terms both attract superior men on an average and enable them to acquire parliamentary knowledge and public weight; its committees are still its servants rather than its masters — preparing legislation for it to discuss, rather than merely killing most of it, and leaving the rest to run in an undiscussed huddle through the open sluice at the last; and it has time and rules that permit some genuine argument, for its own and the public's enlightenment. But these very terms render seats so valuable and desirable that members are more loath to peril them than House seats; and the Senate, which was expected to have more independence than the House from the length of terms, has actually of late years had less backbone and less willingness to run counter to popular currents within its own party than the House. Moreover, the license of debate has too often been a mere license of wanton obstruction, bringing forward no new facts or illuminating discussion, but only exhibiting the spectacle of the will of 100,000,000 people nullified by one or two of its servants. This does not contradict, but only supplements, the other evil. On the other hand, the unity and dispatch of public business made possible in the House by the nominal autocracy and real leadership of the Speaker, aided by the committees and the previous question, have made it seem more and more the body where something is accomplished and the will of the people carried into execution.

(3) The drift of our form of government, and the coming position of Congress and its organs within it, are to some extent matters of prophecy rather than fact; and political philosophers have been busy with them. But some things are certain, and though commonplace, must be recited. Chief of them are the control of the Speaker and the committees over legislation. That the Speaker is a totally different officer from the English Speaker is obvious. He puts motions, decides question of rule and order, and represses disorder, it is true; but instead of being a sworn judge he is a recognized party chief, with functions which approximate the English premier much more closely than the other. By his appointment of the committees he determines the line which legislation shall take, and in a broad way the bills which shall or shall not be considered; and by his daily power of recognizing members who wish the floor, in which he is held to none but party responsibility, he still further molds the total impression which the measures shall make on the public. But he is no autocrat; his very influence can only be exercised by appointing the chief party leaders to the committees, and once there, it is they and not he who hold the decisive power; he and they together, in fact, form something like the shaping committee which

is what the English Cabinet, headed by the premier, has fully become. The Cabinet officers, moreover, are fast becoming advisers of the committees rather than of the President. These approximations to the English position have caused many to think that the transformation will be fully carried out, and the parliamentary system established in fact if not in form in the future; the speaker having the full power of the premier, and the President becoming a dignified nullity like the sovereign of England. But there are still some vital differences, and it is not easy to foresee the process by which they will be overcome. It is true that the admission of Cabinet officers to the floor of either House, to expound their views and needs and explain doubtful questions, is within a simple permissive vote of that House at any time, and can perfectly well be made a standing rule; and that the consequent necessity of their being skilful speakers and capable expositors would profoundly modify the character of men chosen for that position. But the committee do not want information on the floor of the House of Representatives at least: they have no time to attend to it there, and the rules would mostly shut it off before anything material had been communicated. They want it in their committee rooms, and that needs no change in the men and would involve none before the public. The officers cannot become primarily public speakers and secondarily executive officers unless the House gives up its time to debate; and the whole tendency is the other way, nor is it evident where the new time would be found or taken. The place where the change would have to take place is in the Senate, if at all; but the power of legislation more and more drifts away from the Senate except as concurrent; and the new debaters, if they arrive, will seemingly be more in the position of those in the House of Lords than of Commons, which would be immaterial. Still greater is the obstacle of fixed terms. The English members of the Commons remain no longer when the people vote that they do not want them, and it is consequently the great party object to obtain such a vote and to put the other party in a position where they must be disgraced if they do not ask the people to give one pro or con. But the American member must serve out his term, and he can do so if his party has lost all public favor: the tremendous sweep of 1874 did not shorten any Republican member's term for a day, nor imperil any piece of Republican legislation, for which they had an entire session after they were voted down, and as many special ones as the President had chosen to call; and similarly with reverses of the other side. This alone prevents debate from taking up time in the House; it is mainly a sham battle, the real one having been fought in committee. Still further, the English committee called the Cabinet is all of one party, represents it, goes down with it; and the bills it puts forward are the party's bills.

F. M. COCKRELL,
Late United States Senator from Missouri.

CONGRESS OF THE UNITED STATES, Sessions of and Political Parties in. In accordance with the usage of the 'Annals of Congress,' the 'Register of Debates in Congress,' the *Congressional Globe* and the *Congressional Record,* we have used the legislative day for the termination of the first 56 Congresses and the calendar day beginning with the 57th Congress in 1901. The practice of Congress in this connection is based on the fact that it does not recognize the calendar day but only the legislative day, nor are Sundays and the forenoon of 4 March recognized as legislative days. The legislative day of 3 March does not expire until 12 o'clock noon of 4 March. In the *Monthly Catalogue United States Public Documents* (No. 195, p. 492, March 1911) issued by the superintendent of public documents, is the following note:

"If on any day either Senate or House refuses to adjourn, but instead takes a recess, no matter of what duration, the legislative day continues without regard to the almanac. This prolongation of the legislative day has, under the rules, various effects upon the status and the progress of pending bills and motions. . . . Whatever they may be, the legislative day remains simply a legislative fiction. The calendar day, the real day, of course can not be affected by any action of Congress. In the Proceedings of Congress as reported in the Congressional Record both the fictitious legislative date and the true calendar date have been published in recent years when the two dates conflict. Of course as a general rule the two dates harmoniously agree. It is only when a parliamentary struggle or 'filibuster' is afoot that the fictitious legislative day sets the Gregorian calendar at defiance. Almost the only cases in which the recognition of the legislative day affects the accuracy of the public records is when it makes the sessions of Congress seem to have closed at a time when they really did not close.

. . . . . .

"The Constitution fixes the duration of Congressional terms, but the constitutional provision has been differently construed at different periods. In the early years of the Republic it was generally held that the term of a Congress lawfully ended at midnight of March 3 in the odd-numbered years. As a matter of fact it never did end then. The work of legislation was usually continued far into the small hours of March 4, despite earnest protests often made. Finally, March 3, 1851, both the Senate and the House took official action determining that the legal date for the closing of Congress is 12 o'clock noon of March 4 (Consult A. C. Hinds, 'Precedents of the House of Representatives,' Vol. V, pp. 862–863). This ruling has been ever since invariably followed. Whenever the legislative varies from this date as the closing date of a Congress it is wrong. Minor departures, provided for by turning back the official clocks, and winked at by all departments of the government, have of course been disregarded in compiling the check list."

In spite of this ruling and another in 1881, however, the *Congressional Record* continued to use the old legislative day as the running headline date until the end of the 56th Congress in 1901, though the text indicates the calendar days covered by the legislative days, which is very apt to confuse one not accustomed to this method. Moreover, in several instances (as in the last sessions of the 39th, 50th, 53d and 56th Congresses) 3 March was Sunday, wherefore the *Record* is antedated to 2 March (Saturday), though the pages of the volumes themselves indicate not only that Congress sat on Sunday but also on Monday, 4 March. Hence, while the *Record* shows that in these cases a member of either House made a speech on Monday, 4 March, calendar day, he is said to have spoken on Saturday, 2 March, legislative day.

Another source of probable confusion to those unfamiliar with Congressional proceedings is the method pursued by Gales and Seaton in printing the 'Annals of Congress.' The proceedings of some special sessions will be found in the volumes containing the proceedings of the Congress which had just expired. For instance, the proceedings of the special session of the Senate 8–26 June 1795 (which was a part of the 4th Congress) will be found at the end of the proceedings of the second session of the 3d Congress. As they are incorporated there

without explanation or comment of any kind, the reader may be misled into supposing that this session of the Senate belonged to the 3d Congress.

When the government came into being in 1789 there were two parties — the Federalist and Republican, which, like European and English parties, were based largely on class distinctions. For all practical purposes the first session of Congress was non-partisan, since the few Senators and Representatives who openly avowed anti-Federalist sentiments never acted together as a party. But when the measures of Alexander Hamilton (q.v.) were introduced and pushed, the opposition gradually began to assume permanent form, though members did not consider themselves strictly party men. The following figures indicate as nearly as possible the number of those who upheld and those who feared and disliked the government and its measures.

FIRST CONGRESS

First session — 4 March to 29 Sept. 1789.
Second session — 4 Jan. to 12 Aug. 1790.
Third session — 6 Dec. 1790 to 3 March 1791.
Senate — 17 Administration; 9 Opposition.
House — 38 Administration; 26 Opposition.
Speaker of House — Frederick A. Muhlenberg (Pa.), Opposition.

After the first Congress opinions became more widely divergent and to the followers of Jefferson and Hamilton the names of Republicans and Federalists began to be attached. Still many members of Congress were pleased to call themselves independents, and not before the end of Washington's second term did party loyalty in its strict sense make its appearance. At the opening of the second Congress, the Federalists, being in the majority, took away the speakership from Muhlenberg and gave it to a recognized supporter of the administration.

SECOND CONGRESS

Special session of Senate — 4 March 1791.
First session — 24 Oct. 1791 to 8 May 1792.
Second session — 5 Nov. 1792 to 2 March 1793.
Senate — 16 Federalists; 13 Republicans.
House — 37 Federalists; 33 Republicans.
Speaker of *House* — Jonathan Trumbull (Conn.), Federalist.

In the third Congress the party majorities were reversed, and accordingly the Republicans again placed Muhlenberg in the Speaker's chair. From this time the election of a Speaker was indicative of the party strength in the lower house, whereas the office of President pro tempore of the Senate, though regarded as a party office, did not carry with it in later years the power accorded to the Speaker and hence never involved a test of party strength. For that reason no mention is made here of Presidents pro tempore of the Senate.

THIRD CONGRESS

Special session of Senate — 4 March 1793.
First session — 2 Dec. 1793 to 9 June 1794.
Second session — 3 Nov. 1794 to 3 March 1795.
Senate — 13 Republicans; 17 Federalists.
House — 57 Republicans; 48 Federalists.
Speaker — Frederick A. Muhlenberg (Pa.), Republican.

In the fourth Congress the parties were nearly evenly divided, but while at the outset the Republicans were supposed to have a majority, a moderate Federalist was elected Speaker, and on all important administrative measures the Federalists were able to control a majority. After the fourth Congress, however, party lines became fixed and easily distinguishable, wherefore the division in each house can be clearly indicated.

FOURTH CONGRESS

Special session of Senate — 8–26 June 1795.
First session — 7 Dec. 1795 to 1 June 1796.
Second session — 5 Dec. 1796 to 3 March 1797.
Senate — 13 Republicans; 19 Federalists.
House — 52 Republicans; 54 Federalists.
Speaker — Jonathan Dayton (N. J.), Federalist.

FIFTH CONGRESS

Special session of Senate — 4 March 1797.
First session — 15 May to 10 July 1797.
Second session — 13 Nov. 1797 to 16 July 1798.
Special session of Senate — 17–19 July 1798.
Third session — 3 Dec. 1798 to 3 March 1799.
Senate — 20 Federalists; 12 Republicans.
House — 58 Federalists; 48 Republicans.
Speaker — Jonathan Dayton (N. J.), Federalist; George Dent (Md.), pro tempore.

SIXTH CONGRESS

First session — 2 Dec. 1799 to 14 May 1800.
Second session — 17 Nov. 1800 to 3 March 1801.
Senate — 19 Federalists; 13 Republicans.
House — 64 Federalists; 42 Republicans.
Speaker — Theodore Sedgwick (Mass.), Federalist.

SEVENTH CONGRESS

Special session of Senate — 4–5 March 1801.
First session — 7 Dec. 1801 to 3 May 1802.
Second session — 6 Dec. 1802 to 3 March 1803.
Senate — 18 Republicans; 14 Federalists.
House — 69 Republicans; 36 Federalists.
Speaker — Nathaniel Macon (N. C.), Republican.

EIGHTH CONGRESS

First session — 17 Oct. 1803 to 27 March 1804.
Second session — 5 Nov. 1804 to 3 March 1805.
Senate — 25 Republicans; 9 Federalists.
House — 102 Republicans; 39 Federalists.
Speaker — Nathaniel Macon (N. C.), Republican.

NINTH CONGRESS

Special session of Senate — 4–6 March 1805.
First session — 2 Dec. 1805 to 21 April 1806.
Second session — 1 Dec. 1806 to 3 March 1807.
Senate — 27 Republicans; 7 Federalists.
House — 116 Republicans; 25 Federalists.
Speaker — Nathaniel Macon (N. C.), Republican.

TENTH CONGRESS

First session — 26 Oct. 1807 to 25 April 1808.
Second session — 7 Nov. 1808 to 3 March 1809.
Senate — 28 Republicans; 6 Federalists.
House — 118 Republicans; 24 Federalists.
Speaker — Joseph B. Varnum (Mass.), Republican.

ELEVENTH CONGRESS

Special session of Senate — 4–7 March 1809.
First session — 22 May to 28 June 1809.
Second session — 27 Nov. 1809 to 1 May 1810.
Third session — 3 Dec. 1810 to 3 March 1811.
Senate — 28 Republicans; 6 Federalists.
House — 94 Republicans; 48 Federalists.
Speaker — Joseph B. Varnum (Mass.), Republican.

TWELFTH CONGRESS

First session — 4 Nov. 1811 to 6 July 1812.
Second session — 22 Nov. 1812 to 3 March 1813.
Senate — 30 Republicans; 6 Federalists.
House — 108 Republicans; 36 Federalists.
Speaker — Henry Clay (Ky.), Republican.

THIRTEENTH CONGRESS

First session — 24 May to 2 Aug. 1813.
Second session — 6 Dec. 1813 to 18 April 1814.
Third session — 19 Sept. 1814 to 3 March 1815.
Senate — 27 Republicans; 9 Federalists.
House — 112 Republicans; 68 Federalists.
Speakers — 1813–14, Henry Clay (Ky.), Republican; 19 Jan. 1814–15, Langdon Cheves (S. C.), Republican.

After the War of 1812 came the era of good feeling, during which there was practically no opposition in Congress to Madison and Monroe, and while the old names persisted they ceased to have any political significance, beyond the

fact that few Federalists were appointed to offices under the national government. After 1815 the members of the House ceased to vote for a separate candidate for Speaker, so that it is almost impossible to state precisely the number of Federalists in Congress. Even in 1824, when the Republican presidential nomination was to be made, a rough guess placed the number of Federalists in Congress at 40 or 45, but this was only conjecture. However, as closely as it is possible to come, the division was as follows:

FOURTEENTH CONGRESS

First session — 4 Dec. 1815 to 30 April 1816.
Second session — 2 Dec. 1816 to 3 March 1817.
Senate — 25 Republicans; 11 Federalists.
House — 117 Republicans; 65 Federalists.
Speaker — Henry Clay (Ky.), Republican.

FIFTEENTH CONGRESS

Special session of Senate — 4–6 March 1817.
First session — 1 Dec. 1817 to 20 April 1818.
Second session — 16 Nov. 1818 to 3 March 1819.
Senate — 34 Republicans; 10 Federalists.
House — 141 Republicans; 42 Federalists.
Speaker — Henry Clay (Ky.), Republican.

SIXTEENTH CONGRESS

First session — 6 Dec. 1819 to 15 May 1820.
Second session — 13 Nov. 1820 to 3 March 1821.
Senate — 35 Republicans; 7 Federalists.
House — 156 Republicans; 27 Federalists.
Speakers — 1819–20, Henry Clay (Ky.), Republican; 15 Nov. 1820–21, John W. Taylor (N. Y.), Republican.

SEVENTEENTH CONGRESS

First session — 3 Dec. 1821 to 8 May 1822.
Second session — 2 Dec. 1822 to 3 March 1823.
Senate — 44 Republicans; 4 Federalists.
House — 158 Republicans; 25 Federalists.
Speaker — Philip P. Barbour (Va.), Republican.

EIGHTEENTH CONGRESS

First session — 1 Dec. 1823 to 27 May 1824.
Second session — 6 Dec. 1824 to 3 March 1825.
Senate — 44 Republicans; 4 Federalists.
House — 187 Republicans; 26 Federalists.
Speaker — Henry Clay (Ky.), Republican.

In 1825 Jackson became the presidential nominee of those opposed to the administration of President John Quincy Adams, which opposition ultimately developed into the Democratic party. But Jackson's adherents had no definite policy in Congress, their main object being to elect Jackson, and hence the existence of Jacksonian majorities in the Houses of Congress had no legislative significance. With the Jacksonians it was purely a question of loyalty to their chief, and so long as he had no Congressional policy, his followers might differ widely on all other national issues save that of placing Jackson in the presidential chair. For some years the actual leadership in legislation was exercised by the minority members. In 1828 those who supported Adams took the name National Republicans, and the Jacksonians became known as Democrats.

NINETEENTH CONGRESS

Special session of Senate — 4–9 March 1825.
First session — 5 Dec. 1825 to 22 May 1826.
Second session — 4 Dec. 1826 to 3 March 1827.
Senate — 26 Administration; 20 Jacksonians.
House — 105 Administration; 97 Jacksonians.
Speaker — John W. Taylor (N. Y.), Administration.

TWENTIETH CONGRESS

First session — 3 Dec. 1827 to 26 May 1828.
Second session — 1 Dec. 1828 to 3 March 1829.
Senate — 28 Jacksonians; 20 Administration.
House — 119 Jacksonians; 94 Administration.
Speaker — Andrew Stevenson (Va.), Jacksonian.

TWENTY-FIRST CONGRESS

Special session of Senate — 4–17 March 1829.
First session — 7 Dec. 1829 to 31 May 1830.
Second session — 6 Dec. 1830 to 3 March 1831.
Senate — 26 Democrats; 22 National Republicans.
House — 139 Democrats; 74 National Republicans.
Speaker — Andrew Stevenson (Va.), Democrat.

In the 22d Congress appeared some members of the Anti-Masonic party and there were some Democrats, followers of Henry Clay, who termed themselves Clay Democrats. After 1833 Jackson began to lose his following owing to his nullification policy (when the Nullifiers formed a separate faction) and his determination to have Van Buren succeed him in the Presidency, which drove into opposition a number of "State rights" Democrats. In the 24th Congress the National Republicans, Anti-Masons and State Rights or anti-Van Buren Democrats banded together as Whigs. After Van Buren became President, the Democrats who opposed the sub-treasury plan became known as Conservatives, while a group of former State Rights Whigs supported Van Buren's policy and the Nullifiers rejoined the Democratic party.

TWENTY-SECOND CONGRESS

First session — 5 Dec. 1831 to 16 July 1832.
Second session — 3 Dec. 1832 to 2 March 1833.
Senate — 25 Democrats; 21 National Republicans; 2 Anti-Masons.
House — 141 Democrats; 58 National Republicans and Clay Democrats; 14 Anti-Masons.
Speaker — Andrew Stevenson (Va.), Democrat.

TWENTY-THIRD CONGRESS

First session — 2 Dec. 1833 to 30 June 1834.
Second session — 1 Dec. 1834 to 3 March 1835.
Senate — 20 Democrats; 6 State's Rights; 2 Nullifiers; 20 National Republicans.
House — 147 Democrats; 10 State's Rights; 7 Nullifiers; 43 National Republicans; 53 Anti-Masons.
Speakers — 1833–34, Andrew Stevenson (Va.), Democrat; 2 June 1834–35, John Bell (Tenn.), Democrat.

TWENTY-FOURTH CONGRESS

First session — 7 Dec. 1835 to 4 July 1836.
Second session — 5 Dec. 1836 to 3 March 1837
Senate — 27 Democrats; 25 Whigs.
House — 145 Democrats; 98 Whigs.
Speaker — James K. Polk (Tenn.), Democrat.

TWENTY-FIFTH CONGRESS

Special session of Senate — 4–10 March 1837.
First session — 4 Sept. to 16 Oct. 1837.
Second session — 4 Dec. 1837 to 9 July 1838.
Third session — 3 Dec. 1838 to 3 March 1839.
Senate — 30 Democrats; 3 Conservatives; 1 Nullifier; 18 Whigs.
House — 108 Democrats; 13 Conservatives; 11 Sub-Treasury Whigs; 107 Whigs.
Speaker — James K. Polk (Tenn.), Democrat.

Beginning with the 26th Congress, the various factions opposed to Van Buren united under the name Whig and for the next 16 years, despite all disturbing influences, the two-party system held sway. In the 27th and 28th Congresses a few members were known as Tylerites but were soon absorbed in the Democratic party, while in the next Congress appeared the Native Americans who represented a movement against foreigners in the larger cities (see AMERICAN PARTY). From 1849 to 1855 Congress contained a number of Free-Soilers, or Free Democrats as they afterward called themselves, composed of about an equal number of former Whigs and Democrats.

TWENTY-SIXTH CONGRESS

First session — 2 Dec. 1839 to 21 July 1840.
Second session — 7 Dec. 1840 to 3 March 1841.
Senate — 28 Democrats; 22 Whigs.
House — 124 Democrats; 118 Whigs.
Speaker — R. M. T. Hunter (Va.), Democrat.

TWENTY-SEVENTH CONGRESS

Special session of Senate — 4–15 March 1841.
First session — 31 May to 13 Sept. 1841.
Second session — 6 Dec. 1841 to 31 Aug. 1842.
Third session — 5 Dec. 1842 to 3 March 1843.
Senate — 28 Whigs; 22 Democrats; 2 Tylerites.
House — 133 Whigs; 102 Democrats; 6 Tylerites.
Speaker — John White (Ky.), Whig.

TWENTY-EIGHTH CONGRESS

First session — 4 Dec. 1843 to 17 June 1844.
Second session — 2 Dec. 1844 to 3 March 1845.
Senate — 25 Democrats; 28 Whigs; 1 Tylerite.
House — 142 Democrats; 79 Whigs; 1 Tylerite.
Speaker — John W. Jones (Va), Democrat; George W. Hopkins (Va.), pro tempore.

TWENTY-NINTH CONGRESS

Special session of Senate — 4–20 March 1845.
First session — 1 Dec. 1845 to 10 Aug. 1846.
Second session — 7 Dec. 1846 to 3 March 1847.
Senate — 31 Democrats; 25 Whigs.
House — 143 Democrats; 77 Whigs; 6 Native Americans.
Speaker — John W. Davis (Ind.), Democrat.

THIRTIETH CONGRESS

First session — 6 Dec. 1847 to 14 Aug. 1848.
Second session — 4 Dec. 1848 to 3 March 1849.
Senate — 36 Democrats; 21 Whigs; 1 Independent.
House — 108 Democrats; 115 Whigs; 4 Independents.
Speaker — Robert C. Winthrop (Mass.), Whig.

THIRTY-FIRST CONGRESS

Special session of Senate — 5–23 March 1849.
First session — 3 Dec. 1849 to 30 Sept. 1850.
Second session — 2 Dec. 1850 to 3 March 1851.
Senate — 35 Democrats; 25 Whigs; 2 Free-Soilers.
House — 112 Democrats; 109 Whigs; 9 Free-Soilers.
Speaker — Howell Cobb (Ga.), Democrat; Robert C. Winthrop (Mass.), Whig, pro tempore.

THIRTY-SECOND CONGRESS

Special session of Senate — 4–13 March 1851.
First session — 1 Dec. 1851 to 31 Aug. 1852.
Second session — 6 Dec. 1852 to 3 March 1853.
Senate — 35 Democrats; 24 Whigs; 3 Free-Soilers.
House — 140 Democrats; 88 Whigs; 5 Free-Soilers.
Speaker — Linn Boyd (Ky.), Democrat.

THIRTY-THIRD CONGRESS

Special session of Senate — 4 March to 11 April 1853.
First session — 5 Dec. 1853 to 7 Aug. 1854.
Second session — 4 Dec. 1854 to 3 March 1855.
Senate — 38 Democrats; 22 Whigs; 2 Free-Soilers.
House — 159 Democrats; 71 Whigs; 4 Free-Soilers.
Speaker — Linn Boyd (Ky.), Democrat.

In 1854 the dispute over the Missouri Compromise (q.v.) caused a split in the Whig party, most of the Southern members and many of the Northern joining a new party called the American or Know-Nothing party. The other Northern Whigs, the Free-Soilers and a few Democrats united to form the new Republican party (q.v.). When the 34th Congress convened there was much confusion as to exact party adhesion but by the second session there were three fairly well-defined groups.

THIRTY-FOURTH CONGRESS

First session — 3 Dec. 1855 to 18 Aug. 1856.
Second session — 21–30 Aug. 1856.
Third session — 1 Dec. 1856 to 3 March 1857.
Senate — 40 Democrats; 15 Republicans; 5 Americans.
House — 83 Democrats; 108 Republicans; 43 Americans.
Speaker — Nathaniel P. Banks (Mass.), Republican.

In the 35th and 36th Congresses the Democratic party was rent by the dispute over admitting Kansas under the Lecompton Constitution (q.v.), Douglas's followers opposing the administration. When the Civil War broke out in 1861 a Union party made its appearance in the northern slave States, later spread to the free States and ultimately for a short time was united with the Republicans.

THIRTY-FIFTH CONGRESS

Special session of Senate — 4–14 March 1857.
First session — 7 Dec. 1857 to 14 June 1858.
Special session of Senate — 15–16 June 1858.
Second session — 6 Dec. 1858 to 3 March 1859.
Senate — 36 Democrats; 20 Republicans; 5 Americans; 3 Anti-Lecompton Democrats.
House — 118 Democrats; 92 Republicans; 15 Americans; 11 Anti-Lecompton Democrats.
Speaker — James L. Orr (S. C.), Democrat.

THIRTY-SIXTH CONGRESS

Special session of Senate — 4–10 March 1859.
First session — 5 Dec. 1859 to 25 June 1860.
Special session of Senate — 26–28 June 1860.
Second session — 3 Dec. 1860 to 2 March 1861.
Senate — 36 Democrats; 26 Republicans; 2 Americans; 2 Anti-Lecompton Democrats.
House — 92 Democrats; 114 Republicans; 24 Americans; 7 Anti-Lecompton Democrats.
Speaker — William Pennington (N. J.), Republican.

THIRTY-SEVENTH CONGRESS

Special session of Senate — 4–28 March 1861.
First session — 4 July to 6 Aug. 1861.
Second session — 2 Dec. 1861 to 17 July 1862.
Third session — 1 Dec. 1862 to 3 March 1863.
Senate — 31 Republicans; 10 Democrats; 8 Unionists.
House — 105 Republicans; 43 Democrats; 30 Unionists.
Speaker — Galusha A. Grow (Pa.), Republican.

THIRTY-EIGHTH CONGRESS

Special session of Senate — 4–14 March 1863.
First session — 7 Dec. 1863 to 4 July 1864.
Second session — 5 Dec. 1864 to 3 March 1865.
Senate — 36 Republicans; 9 Democrats; 5 Unionists.
House — 102 Republicans; 75 Democrats; 9 Unionists.
Speaker — Schuyler Colfax (Ind.), Unionist.

THIRTY-NINTH CONGRESS

Special session of Senate — 4–11 March 1865.
First session — 4 Dec. 1865 to 28 July 1866.
Second session — 3 Dec. 1866 to 2 March 1867.
Senate — 42 Unionists; 10 Democrats.
House — 149 Unionists; 42 Democrats.
Speaker — Schuyler Colfax (Ind.), Unionist.

The reconstruction question caused an upheaval in political as well as in social life and in the election of the 40th Congress caused a new party alignment, many who had been Unionists during the war period returning to the Democratic party, while the Republican party reappeared as an organization. Since that time the Republican and Democratic organizations have steadily opposed each other in the Congressional government of the country and every effort to destroy or supplant them has failed. After 1870 some Republicans who opposed Grant's administration formed the Liberal Republican party, and in 1872 joined the Democrats in an endeavor to prevent Grant's re-election. In 1876, however, most of the Liberals returned to the Republican ranks. In the 46th to the 49th Congresses were a group of Greenbackers of the so-called National party, and also a faction of Virginians called Readjusters, who ultimately were absorbed by the Republicans.

FORTIETH CONGRESS

Special session of Senate — 1–20 April 1867.
First session — 4–30 March, 3–20 July, 21 Nov. to 2 Dec. 1867.
Second session — 2 Dec. 1867 to 27 July, 21 Sept., 16 Oct., and 10 Nov. 1868.
Third session — 7 Dec. 1868 to 3 March 1869.
Senate — 42 Republicans; 11 Democrats.
House — 143 Republicans; 49 Democrats.
Speakers — Schuyler Colfax (Ind.), Republican; 3 March 1869, Theodore M. Pomeroy (N. Y.) Republican.

FORTY-FIRST CONGRESS

First session — 4 March to 10 April 1869.
Special session of Senate — 12–22 April 1869.
Second session — 6 Dec. 1869 to 15 July 1870.
Third session — 5 Dec. 1870 to 3 March 1871.
Senate — 56 Republicans; 11 Democrats.
House — 149 Republicans; 63 Democrats.
Speaker — James G. Blaine (Me.), Republican.

FORTY-SECOND CONGRESS

First session — 4 March to 20 April 1871.
Special session of Senate — 10–27 May 1871.
Second session — 4 Dec. 1871 to 10 June 1872.
Third session — 2 Dec. 1872 to 3 March 1873.
Senate — 52 Republicans; 17 Democrats; 5 Liberals.
House — 134 Republicans; 104 Democrats; 5 Liberals.
Speaker — James G. Blaine (Me.), Republican.

FORTY-THIRD CONGRESS

Special session of Senate — 4–26 March 1873.
First session — 1 Dec. 1873 to 23 June 1874.
Second session — 7 Dec. 1874 to 3 March 1875.
Senate — 49 Republicans; 19 Democrats; 5 Liberals
House — 194 Republicans; 92 Democrats; 14 Liberals.
Speaker — James G. Blaine (Me.), Republican.

FORTY-FOURTH CONGRESS

Special session of Senate — 5–24 March 1875.
First session — 6 Dec. 1875 to 15 Aug. 1876.
Second session — 4 Dec. 1876 to 4 March 1877.
Senate — 29 Democrats; 45 Republicans; 2 Liberals.
House — 169 Democrats; 109 Republicans; 14 Liberals.
Speakers — 1875–76, Michael C. Kerr (Ind.), Democrat; 4 Dec. 1876–77, Samuel J. Randall (Pa.), Democrat.

FORTY-FIFTH CONGRESS

Special session of Senate — 5–17 March 1877.
First session — 15 Oct. to 3 Dec. 1877.
Second session — 3 Dec. 1877 to 20 June 1878.
Third session — 2 Dec. 1878 to 3 March 1879.
Senate — 36 Democrats; 39 Republicans; 1 Independent.
House — 153 Democrats; 140 Republicans.
Speaker — Samuel J. Randall (Pa.), Democrat.

FORTY-SIXTH CONGRESS

First session — 18 March to 1 July 1879.
Second session — 1 Dec. 1879 to 16 June 1880.
Third session — 6 Dec. 1880 to 3 March 1881.
Senate — 42 Democrats; 33 Republicans; 1 Independent.
House — 149 Democrats; 130 Republicans; 14 Nationalists.
Speaker — Samuel J. Randall (Pa.), Democrat.

FORTY-SEVENTH CONGRESS

Special session of Senate — 4 March to 20 May 1881.
Special session of Senate — 10–29 Oct. 1881.
First session — 5 Dec. 1881 to 8 Aug. 1882.
Second session — 4 Dec. 1882 to 3 March 1883.
Senate — 37 Republicans; 37 Democrats; 1 Independent.
House — 147 Republicans; 135 Democrats; 9 Nationalists; 2 Readjusters.
Speaker — J. Warren Keifer (Ohio), Republican.

FORTY-EIGHTH CONGRESS

First session — 3 Dec. 1883 to 7 July 1884.
Second session — 1 Dec. 1884 to 3 March 1885.
Senate — 36 Democrats; 38 Republicans; 2 Readjusters.
House — 197 Democrats; 118 Republicans; 5 Readjusters; 4 Independents; 1 Nationalist.
Speaker — John G. Carlisle (Ky.), Democrat.

FORTY-NINTH CONGRESS

Special session of Senate — 4 March to 2 April 1885.
First session — 7 Dec. 1885 to 5 Aug. 1886.
Second session — 6 Dec. 1886 to 3 March 1887.
Senate — 34 Democrats; 43 Republicans.
House — 183 Democrats; 140 Republicans; 2 Nationalists.
Speaker — John G. Carlisle (Ky.), Democrat.

FIFTIETH CONGRESS

First session — 5 Dec. 1887 to 20 Oct. 1888.
Second session — 3 Dec. 1888 to 2 March 1889.
Senate — 37 Democrats; 39 Republicans.
House — 169 Democrats; 152 Republicans; 2 Labor; 2 Independents.
Speaker — John G. Carlisle (Ky.), Democrat.

FIFTY-FIRST CONGRESS

Special session of Senate — 4 March to 2 April 1889.
First session — 2 Dec. 1889 to 1 Oct. 1890.
Second session — 1 Dec. 1890 to 3 March 1891.
Senate — 39 Republicans; 37 Democrats.
House — 166 Republicans; 159 Democrats.
Speaker — Thomas B. Reed (Me.), Republican.

Beginning with 1890 the Farmers' Alliance movement, culminating in the People's party, or Populists, disturbed the balance of Republicans and Democrats, and, to add to the confusion, the question of the free coinage of silver was injected into political discussions, so that the two large parties were much cut up, there being Gold Democrats and Silver Republicans. Hence the task of determining the party affiliations of those elected by fusion to these Congresses is very difficult since the claims of partisans vary widely, as do also all contemporaneous statements. But when the free silver issue had been abandoned, the scattered elements again entered the parties of which they had previously been members, and nothing arose to disturb this party alignment until the so-called Bull Moose movement of 1912, when the Republican party was split by the formation of the Progressive party. While the Progressive candidate Roosevelt received 88 electoral votes against eight for the Republican candidate, Taft, the Progressive party had not sufficient strength in Congress materially to influence legislation. In the election of 1916 large numbers of the Progressive voters returned to the Republican party.

FIFTY-SECOND CONGRESS

First session — 7 Dec. 1891 to 5 Aug. 1892.
Second session — 5 Dec. 1892 to 3 March 1893.
Senate — 39 Democrats; 47 Republicans; 2 Populists.
House — 235 Democrats; 88 Republicans; 9 Populists.
Speaker — Charles F. Crisp (Ga.), Democrat.

FIFTY-THIRD CONGRESS

Special session of Senate — 4 March to 15 April 1893.
First session — 7 Aug. to 3 Nov. 1893.
Second session — 4 Dec. 1893 to 28 Aug. 1894.
Third session — 3 Dec. 1894 to 2 March 1895.
Senate — 44 Democrats; 38 Republicans; 3 Populists.
House — 218 Democrats; 127 Republicans; 11 Populists.
Speaker — Charles F. Crisp (Ga.), Democrat.

FIFTY-FOURTH CONGRESS

First session — 2 Dec. 1895 to 11 June 1896.
Second session — 7 Dec. 1896 to 3 March 1897.
Senate — 43 Republicans; 39 Democrats; 6 Populists.
House — 244 Republicans; 105 Democrats; 6 Populists; 1 Silver.
Speaker — Thomas B. Reed (Me.), Republican.

FIFTY-FIFTH CONGRESS

Special session of Senate — 4–10 March 1897.
First session — 15 March to 24 July 1897.
Second session — 6 Dec. 1897 to 8 July 1898.
Third session — 5 Dec. 1898 to 3 March 1899.
Senate — 47 Republicans; 34 Democrats; 5 Populists; 2 Silver.
House — 204 Republicans; 113 Democrats; 11 Populists; 3 Silver; 26 Fusionists (Democrats and Populists).
Speaker — Thomas B. Reed (Me.), Republican.

FIFTY-SIXTH CONGRESS

First session — 4 Dec. 1899 to 7 June 1900.
Second session — 3 Dec. 1900 to 2 March 1901.
Senate — 53 Republicans; 26 Democrats; 5 Populists; 2 Silver; 1 Independent.
House — 185 Republicans; 163 Democrats; 7 Populists; 2 Silver.
Speaker — David B. Henderson (Iowa), Republican.

FIFTY-SEVENTH CONGRESS

Special session of Senate — 4–9 March 1901.
First session — 2 Dec. 1901 to 1 July 1902.
Second session — 1 Dec. 1902 to 4 March 1903.
Senate — 55 Republicans; 31 Democrats; 4 Populists or Silverites.
House — 197 Republicans; 151 Democrats; 9 Fusionists.
Speaker — David B. Henderson (Iowa), Republican.

FIFTY-EIGHTH CONGRESS

Special session of Senate — 5–19 March 1903.
First session — 9 Nov. to 7 Dec. 1903.
Second session — 7 Dec. 1903 to 28 April 1904.
Third session — 5 Dec. 1904 to 4 March 1905.
Senate — 57 Republicans; 33 Democrats.
House — 208 Republicans; 178 Democrats.
Speaker — Joseph G. Cannon (Ill.), Republican.

FIFTY-NINTH CONGRESS

Special session — 4–18 March 1905.
First session — 4 Dec. 1905 to 30 June 1906.
Second session — 3 Dec. 1906 to 4 March 1907.
Senate — 57 Republicans; 33 Democrats.
House — 250 Republicans; 136 Democrats.
Speaker — Joseph G. Cannon (Ill.), Republican.

SIXTIETH CONGRESS
First session—2 Dec. 1907 to 30 May 1908.
Second session—7 Dec. 1908 to 4 March 1909.
Senate—61 Republicans; 31 Democrats.
House—222 Republicans; 164 Democrats.
Speaker—Joseph G. Cannon (Ill.), Republican.

SIXTY-FIRST CONGRESS
Special session of Senate—4–6 March 1909.
First session—15 March to 5 Aug. 1909.
Second session—6 Dec. 1909 to 25 June 1910.
Third session—5 Dec. 1910 to 4 March 1911.
Senate—61 Republicans; 32 Democrats.
House—219 Republicans; 172 Democrats.
Speaker—Joseph G. Cannon (Ill.), Republican.

SIXTY-SECOND CONGRESS
First session—4 April to 22 Aug. 1911.
Second session—4 Dec. 1911 to 26 Aug. 1912.
Third session—2 Dec. 1912 to 4 March 1913.
Senate—41 Democrats; 51 Republicans.
House—228 Democrats; 161 Republicans; 1 Socialist.
Speaker—Champ Clark (Mo.), Democrat.

SIXTY-THIRD CONGRESS
Special session of Senate—4–17 March 1913.
First session—7 April to 1 Dec. 1913.
Second session—1 Dec. 1913 to 24 Oct. 1914.
Third session—7 Dec. 1914 to 4 March 1915.
Senate—51 Democrats; 44 Republicans; 1 Progressive.
House—291 Democrats; 127 Republicans; 9 Progressives; 7 Progressive Republicans; 1 Independent.
Speaker—Champ Clark (Mo)., Democrat.

SIXTY-FOURTH CONGRESS
First session—6 Dec. 1915 to 8 Sept. 1916.
Second session—4 Dec. 1916 to 4 March 1917.
Senate—56 Democrats; 40 Republicans.
House—230 Democrats; 196 Republicans; 7 Progressives; 1 Socialist; 1 Independent.
Speaker—Champ Clark (Mo.), Democrat.

SIXTY-FIFTH CONGRESS
Special session—5 March 1917 to 16 March 1917.
First session—2 April 1917 to 6 Oct. 1917.
Second session—3 Dec. 1917.
Senate—53 Democrats; 42 Republicans.
House—216 Democrats; 210 Republicans; 2 Progressives; 1 Prohibitionist; 1 Socialist; 2 Independent.
Speaker—Champ Clark (Mo.) Democrat.

SIXTY-SIXTH CONGRESS
Sessions—19 May 1919 to 19 Nov. 1919; 1 Dec. 1919 to 5 June 1920; 6 Dec. 1920 to 4 March 1921.
Senate—47 Democrats; 49 Republicans.
House—190 Democrats; 240 Republicans; 2 Independents; 1 Prohibitionist.
Speaker—Frederick H. Gillett (Mass.), Rep.

SIXTY-SEVENTH CONGRESS
Sessions—11 April 1921 to 23 Nov. 1921; 5 Dec. 1921 to 22 Sept. 1922; 20 Nov. 1922 to 4 Dec. 22; 4 Dec. 1922 to 4 March 1923.
Senate—37 Democrats; 59 Republicans.
House—131 Democrats; 301 Republicans; 1 Socialist.
Speaker—Frederick H. Gillett (Mass.), Republican.

SIXTY-EIGHTH CONGRESS
Sessions—3 Dec. 1923 to 7 June 1924; 1 Dec. 1924 to 3 March 1925. *Senate*—43 Democrats; 51 Republicans; 2 Farmer-Labor. *House*—205 Democrats; 225 Republicans; 1 Independent; 1 Farmer-Labor; 1 Socialist; 2 vacancies. *Speaker*—Frederick H. Gillett (Mass.), Rep.

SIXTY-NINTH CONGRESS
Sessions—7 Dec. 1925 to 3 July 1926; 6 Dec. 1926 to 4 March 1927. *Senate*—39 Democrats; 56 Republicans; 1 Farmer-Labor. *House*—183 Democrats; 247 Republicans; 1 Independent; 2 Farmer-Labor; 2 Socialists. *Speaker*—Nicholas Longworth (Ohio), Republican.

SEVENTIETH CONGRESS
Sessions—5 Dec. 1927 to 30 May 1928; 3 Dec. 1928 to 4 March 1929. *Senate*—46 Democrats; 49 Republicans; 1 Farmer-Labor. *House*—195 Democrats; 237 Republicans; 2 Farmer-Labor; 1 Socialist. *Speaker*—Nicholas Longworth (Ohio), Republican.

SEVENTY-FIRST CONGRESS
Sessions—15 Apr. 1929 to 22 Nov. 1929; 2 Dec. 1929 to 3 July 1930; 1 Dec. 1930 to 4 March 1931. *Senate*—39 Democrats; 56 Republicans; 1 Farmer-Labor. *House*—167 Democrats; 267 Republicans; 1 Farmer-Labor. *Speaker*—Nicholas Longworth (Ohio), Republican.

SEVENTY-SECOND CONGRESS
Sessions—7 Dec. 1931 to 16 July 1932; 5 Dec. 1932 to 3 March 1933. *Senate*—48 Democrats; 47 Republicans; 1 Farmer-Labor. *House*—220 Democrats; 211 Republicans; 1 Farmer-Labor. *Speaker*—John N. Garner (Texas), Democrat.

SEVENTY-THIRD CONGRESS
Sessions—9 March 1933 to 15 June 1933; 3 Jan. 1934 to 18 June 1934. *Senate*—60 Democrats; 35 Republicans; 1 Farmer-Labor. *House*—313 Democrats; 113 Republicans; 5 Farmer-Labor. *Speaker*—Henry T. Rainey (Ill.), Democrat.

SEVENTY-FOURTH CONGRESS
Sessions—3 Jan. 1935 to 26 Aug. 1935; 3 Jan. 1936 to June 1936. *Senate*—69 Democrats; 23 Republicans; 1 Farmer-Labor; 1 Progressive. *House*—318 Democrats; 104 Republicans; 3 Farmer-Labor; 7 Progressives. *Speaker*—Joseph W. Byrns (Tenn.), Democrat.

SEVENTY-FIFTH CONGRESS
Sessions—5 Jan. 1937 to 21 Aug. 1937; 15 Nov. 1937 to 21 Dec. 1937; 4 Jan. 1938 to 16 June 1938. *Senate*—76 Democrats; 16 Republicans; 1 Progressive; 2 Farmer-Labor; 1 Independent-Republican. *House*—330 Democrats; 90 Republicans; 8 Progressives; 5 Farmer-Labor; 2 vacant. *Speaker*—William B. Bankhead (Ala.), Dem.

SEVENTY-SIXTH CONGRESS
Sessions—3 Jan. 1939 to 5 Aug. 1939; 21 Sept. 1939 to 3 Nov. 1939; 3 Jan. 1940 to 3 Jan. 1941. *Senate*—69 Democrats; 23 Republicans; 1 Independent; 2 Farmer-Labor; 1 Progressive. *House*—260 Democrats; 169 Republicans; 1 Farmer-Labor; 2 Progressives; 1 American Labor; 2 vacant. *Speakers*—William B. Bankhead (Ala.), Dem. (d. 15 Sept. 1940); Sam Rayburn (Texas), Dem.

SEVENTY-SEVENTH CONGRESS
Sessions—3 Jan. 1941 to 2 Jan. 1942; 5 Jan. 1942 to 16 Dec. 1942. *Senate*—66 Democrats; 28 Republicans; 1 Progressive; 1 Independent. *House*—268 Democrats; 162 Republicans; 3 Progressives; 1 Farmer-Labor; 1 Independent Democrat. *Speaker*—Sam Rayburn (Texas), Democrat

SEVENTY-EIGHTH CONGRESS
Sessions—6 Jan. 1943 to 21 Dec. 1943; 10 Jan. 1944 to 19 Dec. 1944. *Senate*—57 Democrats; 38 Republicans; 1 Progressive. *House*—222 Democrats; 208 Republicans; 1 Farmer-Labor; 2 Progressives; 1 American Labor; 1 vacant. *Speaker*—Sam Rayburn (Texas), Democrat.

SEVENTY-NINTH CONGRESS
Sessions—3 Jan. 1945 to 21 Dec. 1945; 14 Jan. 1946– *Senate*—55 Democrats; 40 Republicans; 1 Progressive. *House*—241 Democrats; 190 Republicans; 1 Progressive; 1 American Labor; 2 vacant. *Speaker*—Sam Rayburn (Texas), Democrat.

CONGRESSMEN, Pay of. An act of 1789 fixed the compensation of congressmen at $6 a day plus $6 for each 20 miles traveled. In March 1816 a fixed salary of $1,500 a year was set but the act was repealed. In 1818 the pay was increased to $8 a day and $8 for each 20 miles traveled. In 1856 the pay was set at $3,000 a year, with mileage; increased in 1866 to $5,000; increased again in 1873 to $7,500, but repealed in 1874. In 1907 the pay was increased to $7,500 and in 1925 to $10,000 a year, with $125 for stationery and $5,000 for clerk hire, plus 20 cents mileage and the franking privilege on official correspondence. The speaker of the House and the president of the senate have received $15,000 a year each since March 4, 1925.

CONGREVE, William, English dramatist: b. Bardsey, near Leeds, 1670; d. London, Jan. 19, 1729. He entered the Middle Temple, London, to prepare himself for the legal profession, but soon deserted the law for literature. At a very early age he wrote a novel entitled *Incognita*, followed by his comedy of the *Old Bachelor*, produced in 1693, and pronounced by Dryden the greatest first play that he had ever beheld. His next play, the *Double Dealer* (1693), was not so successful in representation; but his third, the Comedy of *Love for Love* (1695), proved extremely popular. Its success acquired for the author the patronage of Lord Halifax, who conferred on him several very lucrative posts, so that he was far more prosperous than most men of letters. Not content with his fame in comedy, he essayed tragedy; and in 1697 produced his *Mourning Bride*, the reception of which was extremely favorable. The composi-

tion of four such plays before he had attained the age of 28 is a remarkable proof of early genius in a line of composition demanding great observation and experience. The licentiousness of his writings caused him to be attacked by Jeremy Collier in his *Short View of the Immorality and Profaneness of the English Stage,* to which Congreve published a lame and ineffective reply. He soon after closed his dramatic career with the *Way of the World* (1700), considered by many critics as the most perfect of his comedies, but which was received so coldly that he resentfully determined to relinquish a species of writing in which, upon the whole, he had been eminently successful. A masque, entitled the *Judgment of Paris,* and *Semele,* an opera, neither of which was presented, close the list of his labors for the stage. He, however, continued to write occasional verses on public subjects; and in 1710 published a collection of his plays and poems. Dryden declared him to be the equal of Shakespeare. Steele dedicated to him his *Miscellanies,* and Pope his translation of the *Iliad.* He was buried in Westminster Abbey, where a monument was erected to him by the duchess of Marlborough. Congreve's comedies are chiefly distinguished for the sustained flow of wit in the dialogue. His plays are seldom produced as they are too archaic to have any general popularity. However, revivals of *Love for Love* in 1917, and *The Way of the World* in 1918, 1923, and again in 1927 caused renewed interest in Congreve and his works. Another production of *Love for Love* ran for five performances in New York in 1940. (See WAY OF THE WORLD, THE.) Consult Gosse, E. W., *Life of William Congreve* (1881, new ed. 1924); Taylor, D. C., *William Congreve* (New York 1931); Hodges, J., *William Congreve, the Man* (New York 1941).

CONGRUISM, CONGRUIST, terms derived from the expression *meritum e congruo,* which signifies the view of some writers on the doctrine of divine grace and human merit, that though a man may not in the strict sense merit a given grace or favor of God he may be said to merit in a looser sense, on the ground that there is a certain congruity, a certain fitness with what we believe concerning the relation between man and his Creator, in assuming that the Creator will, out of his infinite mercy, grant to his faithful servants favors that they do not in any tolerable sense of the word merit. An example of *meritum e congruo* is had when a saintly man by his prayers obtains the conversion of a sinner: that conversion is not merited at all in any strict sense; but it is congruous, it is what we like to think about the Creator's love for his chosen ones, that he should be moved to grant the petition of one who is admitted to his friendship.

CONHYDRINE, kŏn-hī'drēn, $C_8H_{17}NO$, a crystalline, dextrorotatory alkaloid of hemlock. It is named chemically as *dextro*-2-α-hydroxypropylpiperidine. It is a strong base and forms numerous salts with acids. It is much less toxic than coniine (q.v.).

CONI, kō'nē, or **CUNEO,** koo-nā'ō, Italy, capital of the province and district of Coni, on a high hill, at the confluence of the Stura and the Gesso, about 55 miles south of Turin, in a pleasant, well-cultivated district. The old fortifications, the arcades along the principal street, a Franciscan church of the 12th century, a handsome town-house, with a tall tower, and a cathedral, are the picturesque items of the town. There are silk spinning-mills, and manufactures of silk, paper and woolen goods. Grain, hemp and silk form articles of commerce. It was taken by Napoleon in 1796, by the Austrians in 1799, and again given up to the French in 1801. Pop. 29,122.

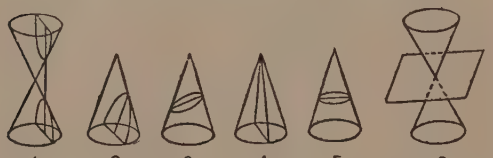
CONIA, or CONIINE, kō'nī-ēn, an alkaloid of hemlock or spotted cowbane, *Conium maculatum* (not to be confused with the hemlock spruce, *Tsuga canadensis*). The hemlock drink used in ancient Greece to inflict the death penalty owed its toxicity chiefly to coniine. The alkaloid was isolated by Giesecke in 1827, and its structural formula was established by Hofmann in 1881, followed by its complete synthesis by Ladenburg in 1886. Coniine has the formula $C_8H_{17}N$, and is a pyridine type, chemical name *dextro*-2-propylpiperidine. It is a colorless, strongly alkaline liquid, dextrorotatory, boiling point 166–167° C., melting point about —2° C.; density at 19° C. 0.8438, refractive index n_D^{23} 1.4505. It is readily soluble in most organic solvents, slightly soluble (1 part in 90) in cold water, less soluble in hot water. In contact with air it slowly turns brown as a result of oxidation. It forms numerous crystalline salts, which are soluble in water or alcohol. The salt with potassium cadmium iodide, melting point 118° C., is used to distinguish it from nicotine. With sodium nitroprusside, $Na_2Fe(CN)_5NO$, it gives a deep red color, which disappears on warming and reappears on cooling.

Coniine has a penetrating disagreeable odor, and a burning nauseous taste, and is exceedingly poisonous. In toxic doses it causes at first nausea and vomiting, paralysis of the motor nerve endings, slowing of the heart, and finally death through respiratory paralysis. The other alkaloids of hemlock have a similar action, but with the exception of *gamma*-coniceine are in general less poisonous. Coniine salts or conium leaves or unripe fruit have been used as a sedative, antispasmodic, or in tetanus, but because of high toxicity and uncertain action are now seldom employed; they are used externally to some extent in ointments for rectal disorders. In the conium fruit coniine (about 0.5–1.5 per cent) is accompanied by *levo*-coniine, N-methylconiine ($C_8H_{16}N{\cdot}CH_3$), *gamma*-coniceine ($C_8H_{15}N$), conhydrine ($C_8H_{17}NO$), and pseudo-conhydrine ($C_8H_{17}NO$). All of these are closely related to coniine chemically. They are found in all parts of the plant, in combination with malic and caffeic acids, from which they may be isolated by treatment with sodium carbonate, followed by steam distillation and separation of the individual alkaloids through their salts. See also ALKALOIDS.

CONIBO, kō-nē'bō, a tribe of Indians belonging to the Panoan family in eastern Peru, allied to the Ucayali tribe. They were an agricultural people and built villages. The Spanish missionaries tried to convert them in 1683, but were driven out after 1695, when Father Ritchie was killed by the savages. They are now partially civilized and are often employed as canoe men and rubber gatherers. Their country is along the middle Ucayali River in north-

eastern Peru. Along the river they are given to fishing; but those back from the water are, many of them, gatherers of sarsaparilla.

CONIC SECTIONS, three curves, the hyperbola, the parabola and the ellipse, are called the conic sections, because these curves are formed by the intersection of the surface of a cone with planes that cut the cone in various directions. If the cutting-plane be parallel to the axis of the cone (fig. 1), the curve formed is the hyperbola, which has two branches, as shown in the figure. If the cutting-plane be parallel to a straight line on the surface of the cone (fig. 2), the curve formed is a parabola. Any other section is an ellipse (fig. 3). It must be noticed, however, that this general description includes three peculiar cases. In the case of a plane parallel to the axis of the cone, when that plane contains the axis, the section, instead of being a hyperbola,



is in this limiting case a pair of straight lines meeting each other at an angle equal to that of the angle of the cone so as to form a triangle (fig. 4). When a plane, which would otherwise form a parabolic section, is a tangent plane to the cone, the parabola degenerates into a straight line passing through the vertex of the cone. Lastly, when a plane that would otherwise form an ellipse is perpendicular to the axis of the cone, the ellipse becomes a circle (fig. 5). Lastly, when a plane cuts the cone only in the vertex, the conic section degenerates into a single point (fig. 6). A pair of points cannot be produced by any plane section of a cone, but on account of its analytical properties, this figure is also considered as a degenerate conic section. The properties of these curves are discussed under their several names. It will there be seen that other definitions may be given of the curves; and that from these their properties are more conveniently derived than from the consideration that they are formed by the sections of a conical surface. The most important of these properties are that of being represented in a system of Cartesian co-ordinates by an equation of the second degree, and that of being the locus of the corresponding lines of two projective pencils in the plane. The properties of these curves are of the greatest physical interest; and the geometry of the conic sections has, ever since the time of the Greek mathematicians, been considered as the best of the more advanced geometrical studies.

CONIFERÆ, a group of trees and shrubs consisting of about 40 genera and 300 species, which are most numerous in the temperate regions of the world, especially in the northern hemisphere. Among the few species found in the tropics, the most important are those belonging to the genera *Araucaria* (q.v.), *Dammara, Phyllocladus* and *Dacrydium.* In the Arctic regions and the correspondingly cold mountain climates various conifers approach very nearly the line of perpetual snow, and like other plants of such climates are reduced to gnarly dwarfed specimens which bear but slight resemblance to those of the same species in less rigorous climates. In the United States and Canada about 15 genera and 100 species and sub-species are indigenous and of these the majority are native to the Pacific coast. In addition to the number of species mentioned fully 400 horticultural varieties must be added. These are listed in Bulletin No. 17 of the Division of Forestry, United States Department of Agriculture.

No forest trees are of more economic importance than the conifers. Their notable blending of maximum strength, stiffness, and durability with minimum weight, and their abundance have won them prominence in house, ship and bridge building, wharf making and sidewalk constructing, etc. They are also of great importance in planting, both for use and ornament, their evergreen habit (except in Larix) and the retention of their lower limbs until comparative age, making them especially good for wind breaks, these characters coupled with their conical form and the striking colors of their foliage rendering them particularly useful for grouping with deciduous trees and shrubs or for individual specimens in parks and upon lawns.

The species are characterized by straight shafts which elongate terminally, and, like the shape of the trees, form a more or less attenuated cone. They have either needle-shaped or awl-shaped leaves (except in *Podocarpus*) which are specially adapted by these forms and by the thickened epidermis to resist excessive transpiration, a necessary adaptation since the leaves are usually retained throughout the year. They have naked ovules which are fertilized directly by the exceedingly light pollen which is produced in enormous quantities and carried by the wind even miles away from the forests, to fall as so-called "showers of sulphur." These ovules are borne in a strobile which enlarges after fertilization into what is popularly known as the cone, the group being named from this character. The cone is an aggregation of scales, above the bases of which are borne the seeds. These are in some species utilized as food, and have been introduced in the markets of the United States by the Syrians. The internal structure of the *conifers* is also peculiar to the group. Like the dicotyledons, the woody cylinder increases in girth by the external development, beneath the bark, of homogeneous woody fibres marked on two sides with circular discs and among which are few true vessels. Since these woody fibres are fitted together without overlapping, the grain of the wood is fine and uniform, which accounts for its easy working qualities, especially in the direction of the "grain."

Botanists divide the species into two great families, the *Taxaceæ* and *Pinaceæ.* The former includes two tribes, *Podocarpeæ,* the leading genus of which is *Podocarpus,* with about 40 species, and *Taxeæ,* chief of which is the genus *Taxus,* the yew. The species of this family have more or less fleshy fruits. The *Pinaceæ* embraces four tribes: *Abieteæ,* the pine family proper, of which the principal genera are *Pinus,* pine; *Picea,* spruce: *Tsuga,*

hemlock; *Abies,* fir; and *Larix,* larch; *Taxodieæ* which includes *Taxodium,* the bald cypress; and *Sequoia,* the redwood; *Cupressineæ,* which includes *Thuya,* arborvitæ; and *Juniperus,* juniper; *Chamæcyparis,* cedar; *Araucarinæ,* including *Araucaria,* Norfolk Island pine and its allies. The most widely distributed of these groups are undoubtedly the genera *Pinus* and *Juniperus,* and the most restricted are *Taxodium,* two species of which are indigenous to the United States and one to China; and *Sequoia,* of which only two species are known, both found in occasional groves on the Pacific Coast. During geological ages these two genera were far more widely distributed.

So far as is known from fossils conifers appeared on the earth in Silurian time, though they may have appeared earlier. They increased and developed during the Devonian and Carboniferous ages. Unlike the acrogens (ferns, ground-pines and horse-tail rushes), the conifers have increased rather than declined since the Carboniferous. Species of yew were abundant in North America in early Devonian time. In the Carboniferous the gymnosperms that grew in the great swamps were related to the cycads and yews. True conifers may have grown upon the drier hillsides. The genus *Walchia* began near the close of the Carboniferous, and in the Permian the conifers included species of *Dadoxylon, Pinites, Ullmania,* etc.; common Triassic conifers are the genera *Voltzia, Baiera* and *Araucarites.*

Conifers are propagated by means of seeds which may usually be obtained in autumn, though some species open their cones at irregular intervals through the winter and others only when artificial heat such as that of a forest fire is applied. The seed should be planted in a sandy loam, given a light mulch, of pine needles or sphagnum, and the seedlings kept free from weeds. They must be kept moist but not wet until they have formed their crown buds, which appear when they are about three months old. If proper methods are practised, transplanting may be done at any time of year, but spring is generally much the best season, since the roots are then most active and the check to growth is least. As a rule conifers do best upon light soils. They are attacked by a large number of insects and diseases both in foliage and trunk but little attention is given in the forest for the control of these pests. Standard fungicides and insecticides may be used effectively in some cases, care being taken to determine the mode of attack of the particular pest. Consult Veitch, 'Manual of Conifers'; Beissner, 'Handbuch der Nadelholzkunde'; Carrière, 'Traité des conifères'; Bailey, 'Standard Cyclopedia of Horticulture.'

CONIINE, CONEINE or **CONNIE.** See CONIA.

CONIMICUT, R. I., village in Kent County; on the Providence River; approximately 8m. S. of Providence. Pop. (1940) about 2,500.

CONINGSBY, a novel by Benjamin Disraeli, Lord Beaconsfield, published 1844. It was his sixth and most successful novel. In three months it had gone through three editions, and 50,000 copies had been sold in England and the United States. It was a novel with a purpose; the author himself explained that his aim was to elevate the tone of public life, to ascertain the true character of political parties and especially to vindicate the claims of the Tories. Incidentally he wished to emphasize the importance of the Church in the development of England, and he tried to do some justice to the Jews. There are more than threescore characters in the book, and part of its popularity came from people's interest in identifying them with men and women prominent in English social and political life.

CONINGTON, John, English classical scholar: b. Boston, Lincolnshire, 10 Aug. 1825; d. there, 23 Aug. 1869. He was educated at Beverley, Rugby, and Oxford, and in 1854 was appointed to the newly founded chair of Latin language and literature at Oxford, which he filled until his death. His greatest work is his edition of 'Virgil' (3 vols., 1861–68), with its singularly subtle and suggestive essays. His edition of the 'Agamemnon' (1848), and 'Choëphori' (1857), of Æschylus are of less moment, though indeed the latter is admirable. In his later years he gave himself much to translation, the results of which were his metrical versions of the 'Odes' of Horace (1863), the 'Æneid' (1866), in Scott's ballad-metre, the 'Iliad' (1868), in the Spenserian stanza, and the 'Satires and Epistles' of Horace (1869), in the couplet of Pope. His writings (with a memoir by H. J. Smith) were edited by J. A. Symonds (London 1872).

CONISTON LAKE, England, a lake in North Lancashire at the eastern foot of the Coniston Fells, nine miles west of Bowness on Windermere. It is five miles long, one-half mile broad, 147 feet above the sea, and its greatest depth is 260 feet. Its waters abound with trout and perch. On the eastern shore stand Ruskin's home, Brantwood and Tent House, once Tennyson's residence. The Old Man of Coniston, to the northwest, is 2,633 feet high.

CONIUM ("spotted hemlock"), the full-grown fruit of *Conium maculatum* gathered while green. *Conium maculatum* is a stout, erect biennial, three to six feet high, with a much branching, smooth, furrowed, dark green hollow stem, covered with purplish spots, very widely present throughout Europe and naturalized in the eastern United States. It grows commonly in wet places, wayside brooks, swamps and dark, moist gardens. All parts of the spotted hemlock are active, but the poisonous principle coniine is found most abundantly in the full-grown but unripe seed, the principle being a volatile alkaloid. Only fresh hemlock is of any service, and much of the lack of uniformity of results in the use of this drug as a remedy has come from the neglect of this precaution on the part of the manufacturers of the drug. The composition of conium is complex. It contains a slight amount of volatile oil and two or three alkaloids, the most important of which is coniine. Coniine is present in small amounts only. It is a strongly basic, colorless, oily liquid, with a penetrating odor and a sharp taste resembling tobacco. It boils at 166° C.; its chemical formula is $C_5H_9,NH,CH_2CH_2CH_3$. It has been made synthetically, being one of the first of the alkaloids thus synthetized. The physiological action of conium is practically identical with the action of coniine. The gen-

eral effect is paralysis of the motor end organs of voluntary muscles; it is thus a motor depressant. It is an irritant to the stomach, increasing the salivary secretions. Its effect on the heart is slight; its effect on the nervous system is very little save in extreme poisoning, when blood changes cause changes in the nervous system. The early symptoms of poisoning are heaviness of the muscles of the legs, and of the eyelids, ptosis, staggering gait, muscular relaxation and muscular paralysis; paralysis of the vocal chords causing derangement of speech; dilatation of the pupil; and finally paralysis of the muscles of respiration with asphyxia, convulsions and death. Treatment of the poisoning is by means of the stomach-pump, strychnine, coffee. Alcohol and rapid elimination by hot baths are desirable.

The therapeutics of conium is restricted. It is very questionable whether it is of use in any affection other than habitual motor spasms of voluntary origin such as spasmodic tics, torticollis and other like affections. It is certainly of very little value in spasmodic affections not associated with voluntary action such as chorea, epilepsy, myoclonus, etc.

CONJEVERAM, kŏn-jē-vēr-ŭm′, **CANCHIPURA** ("the Golden City"), a town of Hindustan, in the presidency of Madras, district of Chinglepat. It stands in a valley, is irregularly built, and from five to six miles long, resembling a series of villages, intermingled with gardens and cocoanut plantations. Conjeveram is one of the Hindu sacred cities, and is sometimes called the "Benares of the south." There are here two splendid pagodas; one dedicated to Vishnu, richly sculptured, and highly venerated; the other, a larger and more imposing structure, dedicated to Siva, from the summit of which a magnificent view is obtained. There are many smaller pagodas; and houses of accommodation for travelers abound. Cottons are manufactured. There is a flourishing school here connected with the Free Church of Scotland. Pop. 43,000.

CONJUGAL RIGHTS (Lat. *conjugalis,* "husband" or "wife"), *in law,* the right which husband and wife have to each other's society, comfort and affection. The suit for restitution of conjugal rights is a matrimonial suit, cognizable in the Divorce Court, which may be brought whenever either the husband or wife lives separate from the other without any sufficient reason. Conjugal rights are matrimonial, nuptial and connubial.

CONJUGATE FOCUS. See LENS.

CONJUGATION (Fr. *conjugation,* Lat. *conjugatio,* "joining together"). In some unicellular plants and in one-celled animals (*Protozoa*), after multiplying by self-division perhaps for many generations, reproduction by germs is brought about by a process called conjugation. It may be illustrated by a flagellate monad (*Heteromita*). In this form two individuals come together and completely fuse, the result is a thin-walled sac (the zygote), the protoplasm of which divides by multiple fission into very minute spores or germs. Each of these spores finally grows to become an adult *Heteromita.* In a much more specialized protozoan (*Paramœcium*), after self-division has been repeated for a certain number of generations, it is interrupted by conjugation. In this case two individuals become applied by their ventral faces, but do not fuse, but the nuclei melt together, so that the fusion of the two individuals takes place, after which the two original infusorians separate. This process is akin to and anticipates sexual reproduction in animals higher than protozoa. The process seems to lend new life to the species; it is a process of rejuvenescence, and is necessary for the maintenance of the life and vigor of the species.

CONJUNCTION, *in astronomy,* one of the aspects of the planets. Two heavenly bodies are in conjunction when they have the same longitude — that is, when the same perpendicular to the ecliptic passes through both. If they have, at the same time, the same latitude — that is, if they are both equally far north or south of the ecliptic — they appear from the earth to be in the same spot of the heavens, and to cover one another. The sun and moon are in conjunction at the period of new moon. In the case of the inferior planets Mercury and Venus, the conjunction is inferior when the planet is between the earth and the sun, and superior when the sun is between the earth and the planet. In general, a heavenly body is in conjunction with the sun when it is on the same side of the earth, and in a line with the sun, and it is in opposition to the sun when it is on the opposite side of the earth, the earth being in a line between it and the sun. Planets are invisible when in conjunction with the sun, except in rare cases when an inferior planet passes over the sun's disc, and may be seen as a speck on his surface. Conjunctions are either geocentric or heliocentric, according as they are actually witnessed from the earth, or as they would be witnessed if observed from the sun. In observing a conjunction from the earth's surface it is usual to reduce the observation to what it would be if made from the earth's centre; by this means the exact times of conjunction are more accurately fixed, and the observations of one astronomer made available to every other, wherever he may be on the earth's surface. Grand conjunctions occur when several stars or planets are found together. Chinese history records one about 2500 B.C., which astronomers calculate actually took place.

CONJUNCTION, that grammatical part of speech which couples words, clauses and propositions. Conjunctions differ from prepositions in their mode of affecting the cases of the nouns which they connect with the previous word or phrase. The preposition is said to govern the noun, that is, to determine its case; the conjunction also may determine the case of a noun, but in a different manner; it always requires the case of the noun or pronoun which follows it to be the same as that of the noun with which it connects the second noun. The conjunction also affects actively the modes of verbs, though less frequently in English than in other languages. Conjunctions are divided into those that co-ordinate the clauses they relate, such as "and," "or," "but," and those that render one clause subordinate to the other, as "if," "for," "when," "notwithstanding that."

CONJUNCTIVA DISEASES. See EYE.

CONJUNCTIVITIS. See EYE.

CONJURATION (Lat. *conjuratio,* "a swearing together," hence conspiracy), a conspiracy, plot or league for criminal ends; the act of calling or invoking by a sacred name; solemn entreaty; *in law,* an unlawful compact formed by oath. The term was formerly used especially in the sense of having personal conference with the devil or some evil spirit to discover secrets or effect some malicious purpose. Closely connected with this use of the word is the secondary meaning of a magical form of words used to invoke supernatural aid through incantation, enchantment or magic spell.

CONJURING, the production of effects apparently miraculous by natural means. The earlier professors of the art claimed bona fide supernatural powers; and in ages when the most elementary principles of physical science were unknown beyond a very limited circle, it was not difficult to gain credence for such a pretension. The modern conjurer makes no such claim, but tells the public frankly that his marvels are illusory. Of the conjurers of remote antiquity we have few reliable records; though it is a tolerably safe conjecture that the prestige of the ancient mysteries rested in no small degree upon effects of natural magic. Perhaps the earliest really trustworthy authority is Reginald Scot, who in his 'Discoverie of Witchcraft' (1584) has enumerated the stock feats of the conjurers of his day.

The conjurers of Scot's time, and those of even much later date, were accustomed, in order to facilitate the substitutions on which a great part of their tricks depended, to wear an apron with pockets, known (from its resemblance to a game-bag) as the *gibecière.* A later school suppressed this tell-tale article of costume, and used instead a table, with cover reaching nearly or quite to the ground. This table concealed an assistant, who worked most of the required transformations, etc., either handing the needful articles to the conjurer as he passed behind the table, or pushing them up through traps in the table-top. Conus the elder, a French conjurer who flourished at the close of the 18th century, made a further improvement by discarding the concealed assistant, and using an undraped table with a secret shelf (now known as the *servante*) behind it, on which his substitutions were made. His immediate competitors did not follow his example, a whole generation of later conjurers, including Comte, Bosco and Philippe, retaining the suggestive draped table. Its death-blow, however, was struck by Robert Houdin (1805–71), with whom about 1844 a new era began. The most modern school of conjurers, following the lead of Wiljalba Frikell, etc., represented by Hartz, Herrmann, Buatier de Kolta, Verbeck, Lynn, Bertram, etc., generally aim at producing their magical results with the minimum of visible apparatus.

The word "conjuring" also still bears all the meanings of *conjuration;* the sense in which the ancient conjurer always used it; and in which medicine men of savage tribes invariably use it to-day.

CONKLIN, Edwin Grant, American zoologist: b. 24 Nov. 1863. Graduated Ohio Wesleyan University (S.B. 1885, A.B. 1886, A.M. 1889, Hon. Sc.D. 1910), Johns Hopkins University (Ph.D. 1891), University of Pennsylvania (Hon. ScD. 1908); trustee Marine Biological Laboratory 1897—; professor of biology Ohio Wesleyan University 1891–94; professor of zoology Northwestern University 1894–96; professor of zoology University of Pennsylvania 1896–1908, and of same at Princeton, 1908. Member American Society of Zoologists, American Society of Naturalists, Fellow of American Association for the Advancement of Science, member National Academy of Sciences, American Academy of Arts and Sciences, foreign member K. K. Böhmische Akademie der Wissenschaften, vice-president Academy of Natural Sciences of Philadelphia, secretary of American Philosophical Society (1900–08), past president American Morphological Society, American Society of Naturalists, Section F (Zoology) American Association for the Advancement of Science, associate editor of *Biological Bulletin, Journal of Morphology, Journal of Experimental Zoology, Proceedings National Academy of Sciences, Genetics;* author of about 100 scientific papers among which the following are the most important: 'Fertilization of the Ovum'; 'The Embryology of Crepidula'; 'The Phenomena and Mechanism of Inheritance'; 'Factors of Evolution'; 'The Organization and Cell-Lineage of the Ascidian Egg'; 'Experimental studies on Nuclear and Cell Division,' 'Cell Size and Body Size'; 'Heredity and Environment,' etc.

CONKLIN, Jennie Maria (DRINKWATER), American author: b. Portland, Me., 14 April 1841; d. New Vernon, N. J., 28 April 1900. She was educated in the public schools, and while still in her teens won fame with her stories for children. In 1880 she married Rev. Nathaniel Conklin. Her works include 'Miss Prudence'; 'Tessa Wadsworth's Discipline'; and 'Fifteen.' She originated the "Shut-In Society," an organization of invalids for correspondence.

CONKLING, Roscoe, American legislator: b. Albany, N. Y., 30 Oct. 1829; d. New York, 18 April 1888. He removed to Utica in 1846, studied law and was admitted to the bar in 1850. He was mayor of Utica in 1858, and sat in Congress as a Republican (1858–62 and 1865–67). During the Civil War he was an active supporter of the administration, appearing constantly in debates and on committees. He was elected to the United States Senate in 1867, 1873 and 1879, and as senator he supported the reconstruction policy, actively opposed President Johnson and was a staunch supporter of President Grant. He was active in almost every move of importance made by his party. He was one of the foremost advocates of the Second Civil Rights Act, in 1875; of the bill creating the Electoral Commission to settle the disputed election of 1876; and of the act calling for the resumption of specie payment (1875). He became an extremely influential member of his party; in 1876 receiving 93 votes for the presidential nomination, and in 1880, by his support of Grant and his personal opposition to Blaine, dividing the Republicans into two sections. In May 1881, he and his colleague, Thomas C. Platt, suddenly resigned from the Senate, owing to a dispute with President Garfield on a question of patronage, and sought re-election; but after a warm canvass, both were rejected, though vigorously supported by Vice-President Arthur. Conkling afterward

practiced law in New York. He was appointed associate chief justice of the United States Supreme Court in 1882, but declined the position. Conkling was a thorough believer in the system of political patronage and he and Platt attempted to say where this patronage should go and to whom in the State of New York.

CONN, Herbert William, American biologist: b. Fitchburg, Mass., 10 Jan. 1859; d. Middletown, Conn., 18 April 1917. He was educated at Boston University and was professor of biology at Wesleyan University, Middletown, Conn. He published 'Evolution of To-day' (1886); 'The Living World' (1891); 'The Story of Germ Life' (1897); 'The Story of the Living Machine' (1890); 'The Method of Evolution' (1900); 'Agricultural Bacteriology' (1902); 'An Elementary Physiology and Hygiene for Use in Schools' (1903); and also over 150 scientific memoirs.

CONN, Lough, lŏH kŏn, a lake in the north of Mayo County, Ireland, united with Lough Cullin by a narrow channel. The two extend for about 13 miles and are studded with islands.

CONNATE WATER. See GROUND WATER.

CONNAUGHT, kŏn'-nât, AND STRATHEARN, DUKE OF, **Arthur William Patrick Albert,** English prince, sixth child and third son of Queen Victoria: b. Buckingham palace, 1 May 1850. He entered the Military Academy at Woolwich as a cadet in 1866; lieutenant, Royal Engineers, 1868; Royal Artillery 1869; captain, Rifle Brigade, 1871. On attaining his majority in 1871, Parliament voted him a grant of $75,000 a year, and an addition of $50,000 was voted on his marriage in 1879 to Princess Louise Margaret of Prussia. She died in London 14 March 1917 at the age of 57. Three children were born of the union, Princess Margaret (late Crown Princess of Sweden), Prince Arthur and the popular Princess Patricia, in whose honor a Canadian regiment mobilized for the war was named "Princess Pat's Own." The Duke of Connaught led an active life of 50 years' public service. In 1870 he served in Canada, was assistant adjutant-general at Gibraltar till 1876, when he was appointed personal aide-de-camp to Queen Victoria. He commanded the Guards' Brigade in the Egyptian campaign of 1882, and in 1886 was sent to India to assume command of the Bombay army. He returned home in 1890, commanded at Portsmouth for three years, and then succeeded Sir Evelyn Wood as commander-in-chief at Aldershot. From 1900 to 1904 he commanded the forces in Ireland and was created field-marshal in 1902. In 1901 the Duke was elected Grand Master of Freemasons in England in succession to his brother, the late King Edward. On the reorganization of the War Office in 1904, he became the first inspector-general of the forces and president of the selection board. In 1908 he was appointed to the newly-created post of commander-in-chief and high commissioner in the Mediterranean. In 1910 the Duke opened the first Parliament under the Union of South Africa, in Cape Town, and in 1911 became governor-general of Canada for five years. Few members of the British royal family saw more of the world than did the Duke of Connaught, who died at his country estate, Bagshot Park, Sussex, England, 16 Jan. 1942. His grandson, the Earl of Macduff, son of Prince Arthur, succeeded to the dukedom.

CONNAUGHT, Ireland, one of the four provinces, bounded east and northeast by Leinster and Ulster, south by Munster, and north and west by the Atlantic; length, north to south, 112 miles; breadth, 99 miles; area, 6,867 square miles. It is the smallest, most westerly and least populous of the provinces. Its west coast is much broken up by numerous bays and inlets, and is thickly studded with islands. The surface is rugged and mountainous, except in the central part, which is comparatively level. It is, on the whole, the least fertile of all the provinces. Agriculture and fishing are the chief industries. Sheep raising is largely engaged in. Connaught was formerly one of the Irish kingdoms. Its kings were of the race of O'Connor, but they were almost exterminated at Athenry in 1305. In 1590 the English divided it into six counties — Galway, Leitrim, Mayo, Roscommon, Sligo and Clare — one of which, county Clare, was afterward transferred to Munster. Pop. 552,757, 96 per cent being Roman Catholics.

CONNEAUT, kŏn'ê-ôt, Ohio, city and port of entry in Ashtabula County; alt. 650 feet; on Lake Erie at the mouth of Conneaut Creek; 70m. NE. of Cleveland; on the New York Central; New York, Chicago and St. Louis; and Bessemer and Lake Erie railroads. It has a good harbor at the mouth of the creek, is an important ore and coal port, transshipping iron ore to Ohio and Pennsylvania mills, and coal to Great Lakes ports; and it exports molding sand, farm produce and fish. Railway repairs, machine shops, tanning, canneries, and the manufacture of garden tools, tin cans, and women's underwear are the principal industries. Lake View Park is along the shore. South of Conneaut is the Old Salt Road laid out in 1804. Barrels of salt were hauled over this road from Conneaut, where they often sold for $20. Settled in 1799, Conneaut became a city in 1898. Pop. (1940) 9,355.

CONNECTICUT, kŏn-nĕt'ĭ-kŭt, «the Nutmeg State,» «the Land of Steady Habits,» or «the Constitutional State» (having framed the first written constitution in America), is the southwesternmost of the six New England States. It is bounded by Massachusetts on the north, Long Island Sound on the south, Rhode Island on the east and New York on the west. Capital, Hartford. Area 5,009 square miles including 110 sq. m. water. Pop. 1,709,242.

History.— There is no doubt that the claim of the Dutch to Connecticut by right of discovery was well founded, for the accounts of the voyages of Henry Hudson in 1609 and of Adrian Bloch in 1614 give the first descriptions which history records of this region. The attempts of the Dutch to maintain their foothold by this right were few and ineffectual, failing to prevent William Holmes of Plymouth colony from establishing a trading post at or near Hartford in 1633.

Settlement.— The first permanent settlement by the English was made in 1636, though a disastrous attempt had been made in the previous year by a party from Massachusetts to occupy the three original towns. In June 1636 Rev. Thomas Hooker and Rev. Samuel Stone, with about 100 men, women and children, made their way from Massachusetts to the Connecticut Val-

Saybrook Lynde Point Light, which guards the seacoast near the mouth of the Connecticut River where it empties into Long Island Sound, located on Lynde Point.

ley, and there re-established the almost abandoned settlements at the three towns which bore the transplanted Massachusetts names of Newtown, Watertown and Dorchester, but were, in the following year, respectively named Hartford, Wethersfield and Windsor. Within a year from the time of this settlement about 30 of the settlers had been wantonly killed by the Pequot Indians, who appeared to be plotting the extermination of the English. In May 1637 Maj. John Mason, with a band of 90 men, was dispatched to attack the Pequots at their stronghold in the present town of Groton. Reaching, by strategic movements, the stockade, where a large number of them were encamped, he took them completely by surprise, killing about 700 by setting fire to their inflammable wigwams and putting to death in hand-to-hand conflict those who escaped the flames. This resulted in the extermination of the Pequot tribe, and secured to the settlers exemption from Indian depredations for all time to come.

The colonists now began to prosper under the leadership of the pastors, Hooker and Stone. Finding themselves outside of the jurisdiction of Massachusetts, to which they at first supposed that they were answerable, they proceeded to form a civil government of their own, adopting in 1639 the Constitution which stands unique in history as the first written constitution of a self-governing people. Its principles had been preached from the pulpit by Thomas Hooker, and its spirit, if not its form, prevailed in the Federal Constitution which was adopted through the influence of Oliver Ellsworth, Roger Sherman and William Samuel Johnson of Connecticut just 150 years later. By this Constitution of 1639 much less rigid ecclesiastical control prevailed than in Massachusetts Bay and Plymouth colonies, the people were recognized as sovereign, and the authority and even the existence of the ruler of Great Britain was ignored. Meantime there had sprung up in Quinnipiack a budding colony, afterward known as New Haven colony, under the leadership of Theophilus Eaton and the Rev. John Davenport. This colony in 1639 adopted resolutions which vested the government in seven pillars of the Church, and disfranchised all who were not church members. In 1662 John Winthrop, the younger, then governor of Connecticut, obtained in England from Charles II a charter which established Connecticut as an independent colony under the constitution already adopted, and defined the boundaries to include New Haven colony, which was thus absorbed, though sorely against its will.

Charter Rights.—From this time onward, for 50 years, Connecticut was engaged in a constant struggle to maintain the rights which the charter had granted. Conflicting grants by Charles II to his brother, then Duke of York; boundary disputes; conflicts of authority with other colonial governors; and the fear that the charter might be annulled by royal decree, kept the statesmen of the day in an attitude of continual vigilance, and schooled them in diplomacy, tact and political alertness. But once in her history, and then only for a year and a half, did Connecticut lose that autonomy which she cherished as her birthright. This was during the usurpation of Andros, in 1687. But the charter was preserved, though Andros demanded it. Its preservation was the result of one of the Yankee tricks for which Connecticut has always been famous, and which may have had something to do with giving her the equivocal title of «the Nutmeg State.» The charter was brought into the general court toward nightfall at Andros' request. Candles were lighted and, by some mysterious agency, suddenly extinguished. During the darkness which prevailed the charter disappeared. Andros assumed the government, and Secretary John Allyn wrote «FINIS» at the close of the record of the proceedings. In May 1689 came the downfall of Andros, and the government and charter reappeared, with the astute Governor Treat once more in the chair, and an undying reverence established for the old charter oak, where, as tradition tells us, Capt. Joseph Wadsworth hid the precious document when it so suddenly disappeared.

War Services.—From the resumption of the government under the charter to the close of the French war in 1763, Connecticut saw much military service, for which she furnished her full quota, on other soils than her own. The short intervals of peace during this long period did not suffice to regain prosperity, and the year 1763 found the colony impoverished by contributions of men and money in the French and Spanish wars, and confronted with the odious news of the Stamp Act. The enforcement of this measure was prevented by compelling the stamp-master to sign a paper stating that he resigned «of his own free will.»

In the War of the Revolution which followed, the share of Connecticut forms a most important feature, still hardly appreciated by historians. The colony was amply, though quietly, prepared in every way for the coming struggle in 1775. Perfect unanimity prevailed. It was unnecessary either to reconstruct the government, as was done in Massachusetts, or to depose the governor, as was done in all the other colonies. Connecticut alone of all the 13 colonies had from the beginning a governor, Jonathan Trumbull, who was an ardent believer in the cause of his country. He became a trusted adviser and helper to Washington. A cherished Connecticut tradition asserts that the national nickname, «Brother Jonathan,» is derived from the fact that Washington had used this sobriquet in speaking of Governor Trumbull. From recent compilations of muster-rolls it is safe to assert that Connecticut furnished 40,000 men in her various enlistments in this war. In the adoption of the Declaration of Independence she was the first colony to instruct her delegates to vote for this measure. During the war, she gained the title of «the Provision State,» owing to the unstinted supplies which she sent to the front in all times of need, relieving, for example, the sufferings of the starving soldiers at Valley Forge by sending forward droves of live cattle when Washington wrote Trumbull that the army must disband unless supplies were forthcoming.

As in the French, Spanish and Indian wars, so in the Revolution, Connecticut's position was, in a certain sense, altruistic, for but little fighting was done on her soil, and it was done at times when her own fighting men were serving their country beyond their own immediate borders. The ravages of two of the most savage

massacres and two of the most barbarous raids of the war brought their horror and devastation to this little commonwealth. The Wyoming massacre was an attack on Connecticut settlers on disputed Connecticut soil, justly claimed under grants of the charter, which extended the western boundaries to the «South Sea» or Pacific Ocean, whose location was majestically ignored by Charles II and his advisers. Wyoming or Westmoreland, now in Pennsylvania, was at the time of the horrible massacre of July 1778 a county of Connecticut, having been previously a part of Litchfield County, and having been for 25 years settled by a Connecticut company after repeated repulses which only served to strengthen resistance and establish an apparently permanent foothold on the part of the settlers. The refugees, of whom women and children composed a large majority, fled to their homes in Connecticut after the massacre, the terrible results of which did not prevent many of the former inhabitants from returning to Wyoming, and once more establishing themselves in that beautiful region from which they had been so often ruthlessly driven. The other massacre, at Groton, occurred toward the close of the war, 6 Sept. 1781. The raid was commanded by Benedict Arnold, to whom it is unfair to attribute the most disgraceful part of it. He was in New London at the time of the occurrence, his troops having burned a large portion of the town. The little garrison of Fort Griswold at Groton made a brave resistance against forces outnumbering them six to one. When, at last, the British entered the fort, Ledyard, the American commander, presented his sword to the officer in command of the British in token of surrender. This brute, whose name, fortunately for his memory, has never been discovered, received the sword and plunged it at once through Ledyard's heart. This was a signal for indiscriminate slaughter, in which hardly a man of this surrendered force was left unhurt, and but few left alive.

The raids of Gov. William Tryon on Danbury in April 1777, and on New Haven, Fairfield and Norwalk, in July 1779, resulted in great destruction of property by fire and plunder, and in the loss of many lives on both sides. It may be truly said that never but twice did these invaders remain on Connecticut soil over night, and in each case took to their ships the next morning with Connecticut troops in hot pursuit.

Notwithstanding the terrible drain which the Revolution made upon her resources, Connecticut, through her wise financial policy, was better prepared, at the close of the war, to avail of the advantages of peace than were any of the other States with the exception of Delaware. It is hardly surprising that the War of 1812 should have been unpopular in Connecticut as well as in all New England; but too much opprobrium has been heaped on Connecticut by giving the protesting convention for all New England the name of the Hartford Convention for the simple reason that it was held, for convenience, in Hartford. It will be found that Connecticut furnished for this war, too, a goodly number of men, though there were some disputes as to the manner and form of doing it. For the half century following this war, peace and prosperity prevailed, broken only by the comparatively insignificant, but sufficient, contribution which was made to the Mexican War.

The outbreak of the Civil War in 1861, like the outbreak of the Revolution in 1775, found Connecticut with a governor in office who was equal to the emergency. Gov. William A. Buckingham, upon his own responsibility, called for a regiment of volunteers, 16 April 1861, when there was not a regiment of organized militia in the State to meet Lincoln's first call. The private citizens and the towns voted money to forward troops; and soon, instead of one, three regiments of volunteers reported for service, making it necessary for the governor to go to Washington to have three times the quota accepted under the call. At the close of the war, the official record shows that Connecticut had furnished 54,882 volunteers, which number was largely in excess of her quota.

Industries.— This war stimulated the industries of Connecticut, which had, at the time, reached a high stage of development. The demand which the large and suddenly equipped army and navy of the country made upon these industries could not fail to have this effect. During the years which have followed the War, the development of manufactures has continued to keep up a healthy growth. This little commonwealth, originally composed of intelligent farming communities, has, by a perfectly natural process of evolution, developed into a manufacturing State which, small though it is in area, holds the rank of eleventh in the gross value of its manufactured products, and the rank of second in the per capita value of these products among the 52 States and Territories enumerated in the latest census. Still more significant is the fact that a larger number of patents in proportion to the population have been issued to Connecticut inventors than to those of any other State in the Union during the past 40 years.

It appears to be a fact that in early colonial times the same inventive genius which has developed in this little commonwealth was born of necessity, and that it was transmitted by heredity down to the present day. The first settlers brought with them intelligence, broadened views of ecclesiastical control and little or nothing more. There were no industrial specialists among them; and a century after the towns of the colony had taken root in various parts of the soil the leading townsmen, besides being still farmers with a growing tendency to trade, were each of them equal to any industrial or political emergency which might arise. Diaries covering the first half of the 18th century show, for example, that the diarist was a ship-carpenter, house-carpenter, millwright, surveyor, judge of probate, soldier and deputy to the general assembly, while pursuing the regular occupation of a trading farmer; and that his neighbors were equally versatile in their industrial and political pursuits. This diversity of individual talents naturally grew, in time, to specializing, as the resources and needs of the commonwealth developed. In 1705 the Granby copper mines were discovered, and unprofitably worked, leaving as souvenirs the Granby copper coins, and the old mine itself, which was used as a prison during the Revolution, and abandoned at the time of establishing the State prison at Wethersfield in 1827. Other

attempts at mining for precious metals were equally unsuccessful, but the working of the Salisbury iron mines, which have been in operation since 1730, proved to be a lasting success. From these mines cannon balls, camp-kettles and other useful articles were furnished during the Revolution, including the chains which were used to bar the progress of the British fleet on the Hudson. The anchor of the famous ship *Constitution* was forged from Salisbury iron in later days. The ore is a rich hematite, which, prepared by the use of charcoal, yields pig-iron which rivals the famous product of the Swedish and Norwegian mines.

Manufactures.— As early as 1749 we find that John Allyn had experimented in brass-making; and in 1768 the first paper-mill of Connecticut, if not the first in the country, was successfully established by Christopher Leffingwell of Norwich. Tinware was first made in Berlin in 1770, and furnished for a century or more an important industry in which the Yankee peddler exercised his wit and shrewdness. In 1773 Thomas Harland from London established at Norwich a shop for making and repairing watches and clocks. In this shop Eli Terry learned the mechanism of the time-pieces of the day, and afterward applied his inventive genius to the manufacture of pillar-scroll and case clocks, which he perfected in 1793. Other Connecticut inventors, especially Seth Thomas and Chauncey Jerome, have brought clock-making to, or very near, its present advanced stage. Eli Whitney, the inventor of the cotton-gin, though not a Connecticut man by birth, owed his fortune to the successful manufacture of firearms at New Haven in 1798, after having been robbed of his great invention in the South in 1792.

The first manufacture of sewing-machines on an extended scale was established by Elias Howe, at Bridgeport, followed in the same city by the improvements of Wheeler and Wilson. In 1844 Charles Goodyear of New Haven obtained his first patent for the process of vulcanizing india-rubber, a process entirely of his own discovery, which revolutionized this important industry in his day, or rather made a new and still enormously increasing industry in the use of material which, without this invention, would have continued to occupy an unimportant place in the industries of the world. The invention of electro-silver plating is traced to the Rogers Brothers of Hartford. In 1846 these three brothers, Asa H., William and Simeon S., succeeded, after much experimenting, in finding a successful way of applying this process to articles made of various metals. From small beginnings, the business grew to large proportions, resulting in great establishments in Hartford, Meriden, Waterbury, Norwich and elsewhere.

The manufacture of textile fabrics had its beginnings in a small woolen factory in Hartford in 1788, and a small cotton mill in Vernon in 1804, but the growth of this industry to its present proportions did not begin in any marked degree till after the enactment of the Joint Stock Act, in 1837, allowing small sums to be capitalized and small proprietors to join their forces in manufacturing. This act, forming a long step in the evolution of the modern trust, since it was copied by nearly every State in the Union, and by Great Britain, thus changing the business of the world, was the work of a Connecticut man, Theodore Hinsdale.

Many cotton mills are on the Shetauket, Yantic and Quinnebaug rivers. The Ponemah Company, at Taftville, has a mill, which, when it was built, was the largest cotton mill in the world. The Willimantic Linen Company is one of the greatest thread producers in New England. More than seven-tenths of the cotton spindles of the State are operated at Norwich, Thompson, Plainfield, Killingly and Willimantic. The woolen mills are more widely distributed throughout the State, at Vernon, Stafford, Broad Brook, New Britain, Norwich and elsewhere. Among the textile manufactures that of silk is important, having had its small beginnings so early as 1732 and now placing the State third in the Union in that industry. At present the silk products are valued at about $75,000,000. The works of the Cheney Brothers, at South Manchester, established in 1838, are among the largest in the country.

The manufacture of textiles, including silk, wool, worsted, cotton, felt, hosiery and knit goods, forms one of the leading manufacturing industries of the State. The 1939 census of manufactures showed a total of 2,936 establishments, which gave employment to 233,525 wage-earners, receiving wages amounting to $276,274,243, with manufactured products valued at $1,229,585,778. Waterbury is prominent in making brass. Meriden in silver and plated ware; New Britain (which has the largest proportion of wage-earners, 34.2 per cent, and the greatest number of nationalities represented in its population) in hardware, cutlery and knit goods; New Haven and Bridgeport in firearms, corsets and rubber goods; Hartford in hardware and firearms. The variety of manufactured articles is noticeable, from blotting-paper to aircraft. Connecticut was the leading State in the value of firearms and munitions manufactured in 1910, two-fifths of the total for the United States having been reported; and that amount was vastly increased during the war by the output of Winchester's, Marlin's and Maxim's in New Haven, of the Union Metallic Company and American-British Company in Bridgeport, of Colt's in Hartford, besides other firms in Meriden, Norwich and elsewhere. The prodigious activity of these establishments has added many thousands to the population of those cities. Connecticut ranks first in brass and bronze products, hardware, felt hats, ammunition and plated ware, producing two-thirds of the total amount of the last in the United States; is second in typewriters, corsets, and clocks, and third in metal working machinery and tools and cutlery. Foundry and machine shop products have a large output and electrical machinery also.

Agriculture—Although the history of agriculture in Connecticut presents a contrast to that of manufacturing by showing a decline in proportion to the population, agriculture is still second in importance among industries. It must be remembered that the little commonwealth is the smallest but two of the States and Territories. Its area may be rather indefinitely divided into the central lowland, the coast, the eastern and western uplands. Of these, the central lowland, lying in the valley of the Con-

necticut River, is from Middletown to the northern boundary best adapted to cultivation; and here it was that, after spying out the land, the first colonists, whose sole industry was agriculture, settled.

From Middletown to the coast, the river leaves the lowland and cuts a narrow valley through the eastern upland. The portion of the central lowland between Middletown and New Haven is less fertile. The eastern upland varies in fertility, but contains some rich farming land. It has also the advantage of a lower average elevation than the western upland, where the only mountains of the State are found. One of these, Bear Mountain, reaches an elevation of 2,000 feet or more.

Corn, hay, potatoes and tobacco are the leading crops of Connecticut, but market gardening, poultry raising, and dairy farming are generally regarded as profitable employments. The cultivation of tobacco began in the Connecticut Valley, near Hartford, as early as 1680. Improved methods of curing the harvested plant have added much to its value in recent years, the tobacco being highly regarded for cigar wrappers. Three types are grown—the Havana seed-leaf, principally on the west bank of the Connecticut River; the broad leaf, on the east side of the river, and the shade grown, mostly on the west side of the river. The following tables, compiled from the reports of the United States Bureau of the Census, give the salient statistics relating to certain phases of agriculture in Connecticut:

Item	Census of 1940	Census of 1930
FARMS, FARM ACREAGE AND VALUE		
Number of farms	21,163	17,195
Farms operated by—		
Full owners	17,778	14,271
Part owners	1,492	1,315
Managers	375	541
All tenants	1,518	1,068
Value of farms (land and buildings)	$204,761,302	$227,412,905
Average value per farm	$9,675	$13,226
Average value per acre	$135.41	$151.38
All land in farms, acres	1,512,151	1,502,279
Average acreage per farm	71.5	87.4
FARM LAND ACCORDING TO USE (ACRES)		
Cropland harvested	362,577	372,147
Crop failure	8,461	11,542
Cropland, idle or fallow	55,437	46,899
Plowable pasture	215,595	127,843
Woodland	521,339	599,405
All other land	348,742	344,443
Land available for crops (Harvested, failure, idle or fallow, and plowable pasture)	642,070	558,431
LIVESTOCK ON FARMS (NUMBER)		
Horses and colts	16,714	20,650
Mules and mule colts	284	515
Cattle	156,912	147,444
Cows and heifers 2 years old and over on 1 Jan. of census year	115,547	95,196
Cows and heifers milked	105,019	98,184
Sheep and lambs	4,001	8,953
Hogs and pigs	15,256	16,827
Chickens	1,997,510	1,536,725

ACREAGE AND PRODUCTION OF SELECTED CROPS

(U. S. Department of Agriculture Figures)

Crop	1929–38 Average	1940
Corn:		
Acreage	52,000	49,000
Production—bu.	1,998,000	1,960,000
Hay:		
Acreage	316,000	358,000
Production—tons	416,000	495,000
Tobacco:		
Acreage	17,070	17,400
Production—lbs.	23,108,000	22,996,000
Potatoes:		
Acreage	15,700	18,900
Production—bu.	2,457,000	3,402,000
Apples:		
Production—bu.	1,281,000	1,210,000
Pears:		
Production—bu.	48,000	48,000
Peaches:

Horses	20,650	16,714
Mules	515	284
Cattle	95,196	156,912
Sheep	8,953	4,001
Swine	16,827	15,256

Railroad and Other Companies.—The railroads are the New York, New Haven and Hartford, with 865 miles operated in the State and a total mileage of 2,045.25; New London and Northern, with 56.10 miles in the State, total mileage 58.60 (operated by the Central Vermont); Central New England, with 83.08 miles in the State, total mileage, 522.80 (merged with the New York, New Haven and Hartford in 1927); Hartford and Connecticut Western, leased by Central New England, with 77.26 miles in the State, total mileage, 123.96; Norwich and Worcester, with 53.16 miles in the State, total mileage, 71.07 (operated by New York, New Haven and Hartford); South Manchester, total mileage, 3.15; Brandford (freight only), total mileage, 4.20. The total mileage in the State is 999.58, and the total miles operated by companies in the State, 5,638.01 (all tracks). There are also steamship and ferry lines making the numerous Sound and river ports, besides through and local highway bus lines, some operated in connection with the railways.

Banking.—On 1 Jan. 1939 there were in the State 208 banks of all kinds with total assets of $1,475,372,000. Liabilities of these banks included demand deposits aggregating $304,959,000 and time deposits of individuals, partnerships or corporations aggregating $912,782,000. The banks were capitalized at $45,477,000; had an aggregate surplus of $81,201,000; undivided profits of $37,220,000 and reserves and retirement account totaling $12,767,000. National banks numbered 53 on 2 Oct. 1939 with assets totaling $342,883,000; demand deposits aggregating $165,164,000; time deposits, $87,890,000; capital stock aggregating $21,547,000; surplus of $13,857,000; and undivided profits aggregating $5,120,000. There were 77 State commercial banks with total assets of $343,902,000 and deposits aggregating $290,671,000.

The oldest bank of deposit in the State and the fifth in age in the United States is the Union Bank and Trust Company of New London, chartered in 1792, and still doing business under its old charter. The Middlesex Banking Company, of Middletown, chartered in 1872, was the first mortgage company in the country.

Insurance.—Connecticut is the home of several leading insurance companies of the United States. The business centers in Hartford, where there are now six independent fire companies—the Hartford (largest in the United States), Aetna, Phoenix (also owns the Connecticut Fire but lets it operate separately),

National, Standard, and Hartford County Mutual, besides United States branches of several foreign companies. There are also in Hartford six life insurance companies; two general indemnity companies (branches of the Travelers and Hartford Fire), and the original and largest Steam Boiler Insurance Company in the United States.

Religion.—The ecclesiastical history of Connecticut would fill a large volume, and is an interesting study in the development of religion in this country. It is enough to say that, at the beginning, the colony stood unique as a compromise between the rigid ecclesiasticism of Massachusetts Bay and Plymouth colonies, and the religious liberty which Roger Williams was, at the time, establishing in Rhode Island. Unique though it was, it can be called a theocracy only at the beginning, for the State was then the Congregational Church, pure and simple, and though others than church members could vote, they were obliged by the early code to vote taxes for the support of the church. The process of emancipation from these theocratic conditions was slow, and did not reach perfection until the adoption of the new Constitution in 1818. Through this period of nearly two centuries there were executions for witchcraft at Stratford in 1651; at Fairfield in 1653; and possibly at Windsor in March 1646 or 1647, if the journal of John Winthrop is to be taken as an authority; and in the theological tenets which were adopted from time to time under direction of the general court and otherwise, we pass through a maze of solemn discussions of the Half-way Covenant, the Cambridge Platform, the Saybrook Platform with the later New Lights and Old Lights arrayed against one another as Separatists and Conservatives. Legislation exempting the Church of England from taxation for support of the Congregational Church was had in 1727, and in 1729 was extended to cover cases of the Baptists and Quakers. In 1791, the right of incorporation was allowed, under certain restrictions, to all religious bodies. The first Baptist elder was ordained at New London in 1726, but the sect did not gain largely until the beginning of the 19th century. The Protestant Episcopal Church was not established under a regularly ordained bishop until after 1784, although it had made beginnings before that time, but was practically exterminated during the Revolution, owing to the Toryism of its clergy. In 1789, the first Methodist Episcopal church in the State was established at Stratford. The first Roman Catholic church in Connecticut was established in 1830, and in 1843 the diocese of Hartford, embracing the entire State, was established.

Finances.—Including cash on hand on 30 June 1940 amounting to $34,003,828.14, receipts during the fiscal year 1939–40 aggregated $125,406,843.45. Expenditures during the same period aggregated $101,892,881.95, leaving a balance on hand on 30 June 1940 of $23,513,962.50. On 1 July 1940 the funded debt of the State totaled $23,750,000. It had a floating debt of $450,000. The assessed value of all property in the State was $3,072,460,056, of which amount about 86 per cent was real property and 14 per cent was personal property.

Charitable and Penal Institutions.—The State institutions include: State Hospital, Middletown; Norwich State Hospital; Connecticut Farm for Inebriates, Norwich; State Prison, Wethersfield; State Farm for Women, Bride Lake, Niantic; Connecticut School for Boys, Meriden; Long Lane Farm, Middletown; Fitch's Home for Soldiers, Noroton Heights; Connecticut Reformatory, Cheshire; Mansfield State Training School and Hospital; 5 State tuberculosis sanatoria—one at Hartford, one at Meriden, one at Norwich, one at Shelton, and The Seaside at Niantic; and the Oral School for the Deaf, Mystic. The miscellaneous institutions include: The American School at Hartford for the Deaf, West Hartford; Connecticut Institute for the Blind, Hartford; Newington Home for Crippled Children, Newington; Bridgeport Hospital; Charlotte Hungerford Hospital at Torrington; Danbury Hospital; The Day Kimball Hospital, Putnam; Grace Hospital, New Haven; Hartford Hospital; Old People's Home (Department of Hartford Hospital); the Hospital of St. Raphael, New Haven; Litchfield County Hospital, Winchester; Manchester Memorial Hospital, South Manchester; Lawrence and Memorial Associated Hospitals, New London; the Meriden Hospital; Middlesex Hospital, Middletown; New Britain General Hospital; Norwalk Hospital; Rockville City Hospital; St. Francis Hospital, Hartford; St. Mary's Hospital, Waterbury; St. Vincent's Hospital, Bridgeport; Stamford Hospital; Waterbury Hospital; W. W. Backus Hospital, Norwich; The Griffin Hospital, Derby; The Cyril and Julia C. Johnson Memorial Hospital, Stafford Springs; Hartford Orphan Asylum; New Haven Orphan Asylum; St. Francis Orphan Asylum.

The State Reformatory, opened in 1913, is doing a very satisfactory work, and is an important addition to the correctional work of the State.

Education.—The educational system of Connecticut was planted almost literally with the first corn that was planted by the early settlers. From the small beginning in the few towns, the present system of public schools has been evolved, aided materially in 1795 by the proceeds of the Western Reserve Lands, now in the State of Ohio, which were sold in order to establish a school fund. The lands, to the extent of about 3,500,000 acres, were granted to Connecticut by the United States in 1786 as a tacit compensation for her loss of the Wyoming territory by a decree of 1782. About 500,000 acres were granted by Connecticut to those within her jurisdiction who had suffered from the incursions of the British during the Revolution, and the remaining 3,000,000 acres were sold for the establishment of a school fund. That fund remains intact to the present day, and now amounts to well over $2,000,000, yielding an income of about $90,000. Another fund, known as the town deposit fund, was Connecticut's share of the apportionment from the surplus of the United States Treasury in 1837, and was given by the State to the towns. School attendance is required until the sixteenth birthday.

Control of the schools is largely local and is vested in a board of education in each of the 169 towns of the State. Many of these towns are too small to maintain their own high schools, and at present pay tuition to other towns that do maintain high schools. A portion of this tuition is reimbursed by the State. Recently, a move-

ment has started whereby two or more towns may combine their resources in the support of a regional high school. Six towns are cooperating in the support of the first such school.

Trade education on the secondary level is provided in eleven well-equipped and State-supported trade schools. Here boys and girls learn the skills and fundamental principles of their crafts under the tutelage of practical experts.

PUPILS ENROLLED IN THE PUBLIC SCHOOLS, 1939–40

Elementary schools	171,843
Junior high schools	23,344
High schools	79,654
	274,841

In 1939–40, expenditures for education from State funds were:

Grants-in-aid	$1,873,045
Teachers colleges	596,118
Trade schools	710,649
University of Connecticut	856,565
Teachers Retirement Board	445,468
	$4,481,845

Spent by the towns in current support of public elementary and secondary education in 1939–40, $29,140,037.

State-supported higher education is provided by the four teachers colleges and the University of Connecticut. The teachers colleges, all four-year institutions, are located at Danbury, New Britain, New Haven, and Willimantic. The teachers colleges enrolled 1,188 students in 1939–40, and had 108 faculty members. The University of Connecticut at Storrs, formerly Connecticut State College, includes the divisions of Agriculture, Arts and Sciences, Business and Commerce, Engineering, Home Economics, and Teacher Training as well as graduate instruction in these fields. The faculty numbers 164 and in 1939–40 there were 1,171 students, 782 men and 389 women. The value of the plant was estimated at $5,342,823 and the current annual expenditures for 1939–40 amounted to $1,546,444.

In addition to the public schools, there are a large number of private and parochial schools. Among the private schools are several junior colleges, business colleges, boarding schools, and college preparatory schools. Most of the parochial schools are Roman Catholic, although the Lutherans and one or two other denominations maintain schools in a few communities.

The institutions of higher learning are supported by tuition fees, endowment, or church funds. The principal institutions coming within this category are Yale University at New Haven; Wesleyan University at Middletown; Trinity College at Hartford; the Hartford Seminary Foundation; the Hartford School of Religious Education was affiliated with the seminary in 1902; the Kennedy School of Missions is another affiliate; the Berkeley Divinity School at New Haven; the St. Thomas Catholic Seminary at Bloomfield, the Connecticut College for Women at New London, St. Joseph's College in Hartford and Albertus Magnus in New Haven. Each of these institutions is provided with a library of its own. The library of Yale University contains more than 2,556,000 volumes. The Yale Elizabethan Club owns a magnificent collection of Tudor and Stuart drama, said to be the finest in America to which the general public has access.

The State Library at Hartford contains a large and valuable collection of the laws and official documents of other States and the general government; besides which it has accumulated a general collection in which history is prominent; it also contains many rare and original documents, including the charter of 1662. There are in the State over 200 public libraries.

The principal historical societies are the Connecticut, the New Haven Colony, the New London County, the Middlesex County, the Mattatuck (of Waterbury), Historical societies, and the Bridgeport Scientific and Historical Society.

The growing desire for increasing the artistic sense of the community is shown by the organized efforts in New Haven, Bridgeport, Hartford and other places, for the purpose of developing beauty in their own domains.

Government.— The government of Connecticut has been conducted under two different constitutions, the first of which was adopted in January, 1638–39, and was fortified and protected by the charter of 1662; and the second, which was adopted as the result of a constitutional convention in 1818. This constitution, with its subsequent amendments, forms the organic law of Connecticut at present. Under it the governor, lieutenant-governor, secretary of state, treasurer, comptroller and members of the general assembly are chosen biennially by the people. Other State officers are appointed either by the governor, sometimes with, and sometimes without, the consent of the senate, or by the general assembly.

The Legislature of the State is called the General Assembly and consists of a Senate of 35 members and a House of Representatives of 267 members. It meets bi-ennially on the first Wednesday after the first Monday of January in odd-numbered years. In addition to two Senators, the State is represented in the National Congress by five Representatives elected from districts and one Representative elected at large.

The courts of the State include the Supreme Court of Errors and the Superior Court, the judges serving for terms of eight years; the Court of Common Pleas, and the District Court, for four years, all of these judges being appointed by the general assembly on nomination by the governor. Judges of city, borough and town courts are appointed for terms of two years, by the general assembly. There are in the State 115 probate districts, the judges of which are elected by the people.

COLONIAL GOVERNORS

Connecticut Colony

John Haynes	1639–40	John Webster	1656–57
Edward Hopkins	1640–41	John Winthrop	1657–58
John Haynes	1641–42	Thomas Welles	1658–59
George Wyllys	1642–43	John Winthrop	1659–76
John Haynes	1643–44	William Leete	1676–83
Edward Hopkins	1644–45	Robert Treat	1683–87
John Haynes	1645–46	Edmund Andros	1687–89
Edward Hopkins	1646–47	Robert Treat	1689–98
John Haynes	1647–48	Fitz John Winthrop	1698–1707
Edward Hopkins	1648–49	Gurdon Saltonstall	1707–24
John Haynes	1649–50	Joseph Talcott	1724–41
Edward Hopkins	1650–51	Jonathan Law	1741–50
John Haynes	1651–52	Roger Wolcott	1750–54
Edward Hopkins	1652–53	Thomas Fitch	1754–66
John Haynes	1653–54	William Pitkin	1766–69
Edward Hopkins	1654–55	Jonathan Trumbull	1769–76
Thomas Welles	1655–56		

(Originally no one was to be chosen governor two years in succession; which accounts for the alternating terms of office. In 1660, this restriction was abolished by the free-

men. Until 1752, the legal year in England began 25 March, not 1 January. This, with the difference of 11 days between Old Style and New Style, accounts for many apparent discrepancies in dates).

New Haven Colony

Population.—On 1 April 1940, Connecticut had a population of 1,709,242, an increase of 102,339 or 6.4 per cent over the 1,606,903 residents reported in the 1930 census. The population increase in the urban areas from 1930 to 1940 was 2.3 per cent, as compared with an increase of 16 per cent in the rural sections of the State. The first federal census of Connecticut was taken in 1790, returning a population of 237,946. The population has shown an increase at every census since that time, but the rate of increase from 1930 to 1940 was the lowest since that of 1830 to 1840. Connecticut's population passed 500,000 between 1860 and 1870; 1,000,000 between 1900 and 1910; and 1,500,000 between 1920 and 1930. The 1940 population represents a density of 348.9 inhabitants per square mile. There are 19 cities in the State with populations of 10,000 or more; of these cities, West Hartford town showed the most rapid increase (35.4 per cent) over the 1930 return. Of the eight counties, all gained in population between 1930 and 1940; Tolland County, with an 11.2 per cent increase, had the most extensive growth. The following table gives the population of the State as a whole, with comparative figures for the urban, rural, male, female, white, and nonwhite populations, 1930 and 1940:

POPULATION OF CONNECTICUT

	1940	1930
State	1,709,242	1,606,903
Urban	1,158,162	1,131,770
Rural	551,080	475,133
Male	885,071	801,303
Female	854,171	805,600
White	1,676,121	1,576,700
Nonwhite	33,121	30,203

JONATHAN TRUMBULL,
Revised by ELLEN STRONG BARTLETT.

CONNECTICUT COLLEGE FOR WOMEN, an institution for higher education at New London, Conn. It was chartered 4 April 1911. In 1913 the trustees authorized the erection of an initial group of five buildings, and the college was opened for the reception of students in September 1915. Its foundation was due to the desire of the people of Connecticut to provide within the State adequate facilities for the higher education of women. The campus comprises 350 acres, and the college offers courses leading to the degrees of A.B. and B.S. The institution has received numerous gifts of money, including an endowment of $1,000,000 from Morton F. Plant. In 1937–38 its grounds, buildings and equipment were valued at $3,162,170. Students enrolled in 1937–38 numbered 716, and the teaching staff numbered 73. Volumes in the library, 80,000. General examinations of all students in their major subject was voted a graduation requirement, beginning with the 1939 class.

CONNECTICUT LAKES, four small lakes in the northern part of Coos County, N. H., which are connected with Connecticut River in the beginning of its course. They are named in numerical order, from southwest to northeast, the largest one, Connecticut Lake proper, being known as First Lake. The smallest two, Third Lake and Fourth Lake, which are very near the Canadian boundary, are the ultimate sources of the river.

CONNECTICUT RESERVE. See WESTERN RESERVE.

CONNECTICUT RIVER, a river of New England; it rises in Connecticut Lake on the northern border of New Hampshire, 2,000 feet above sea-level, forms the boundary between Vermont and New Hampshire and flows southward, passing through the western part of Massachusetts, the central part of Connecticut and falls into Long Island Sound. Its total length is about 350 miles, and its drainage basin is more than 11,000 square miles in extent. Its principal affluent is the Farmington which joins it above Hartford. Throughout its course between New Hampshire and Vermont the banks are wooded, the river bed very narrow and all affluents are small, but at certain seasons become so many torrents. The average fall in this upper course is from 18 to 32 feet per mile. After entering Massachusetts the river flows through Triassic shales and sandstones and the river valley becomes very broad. Near the Connecticut border and after its entry into the latter State the river has cut its way through heavy deposits of sand, gravel and clay of the late Glacial Period. This portion is also marked by several rapids and waterfalls; of these the principal are the Enfield Falls, 10 miles above Hartford. The river valley from Middletown to the sea is narrow, the stream here working through the crystalline rocks of the lowlands. The valley is a great manufacturing region, ample water-power being supplied by the river at many points, such as Bellows Falls, Vt., Turners Falls and Holyoke, Mass., and Windsor Locks, Conn. Below Brattleboro, Vt., a great power dam has been constructed recently by the Federal Government. The latter has had elaborate surveys made with a view of rendering the river navigable as far as Holyoke. Subsidiary canals at present make it navigable for about 25 miles above Hartford, while from this city to the sea (50 miles) it is navigable for vessels drawing from eight to 10 feet. The sand bars which are constantly forming at the mouth of the rivers are removed by dredging. In Colonial times the river played a prominent part in the settlement of the region. It was the highway for the English and Dutch fur traders, and the fertility of the lands along its banks soon attracted settlers. Until the advent of the railway it remained the principal thoroughfare between the northland and the sea. Consult Bacon, E. M., 'The Connecticut River and the Valley of the Connecticut' (New York 1906); Genth, M. K., 'Valley Towns of Connecticut' (American Geographical Society, Vol. XXXIX, No. 9, ib., 1907).

CONNECTICUT, University of, at Storrs, Conn. The university was founded in 1881 by act of the General Assembly as the Storrs Agricultural School. In founding the school the State accepted a gift of 170 acres of land and several buildings and $6,000 in money from Charles and Augustus Storrs, brothers, who had in mind a farm school for boys. The first step in expansion came when the General Assembly divided the proceeds of the national Hatch Act of 1887 between the Storrs Agricultural School and the Connecticut Agricultural Experiment Station in New Haven. In 1893 the General Assembly assigned to the school the proceeds of Connecticut's share of the Land Grant Act of 1862. At the same time the name was changed to Storrs Agricultural College. As a part of this change women were for the first time legally admitted to the school.

In 1899 the General Assembly changed the name of the school to Connecticut Agricultural College. The degree of Bachelor of Science was first granted in 1904. In 1933 the General Assembly again changed the name to Connecticut State College. The degree of Bachelor of Arts was first granted in the same year. Six years later, in 1939, the General Assembly changed the name to University of Connecticut.

Collegiate instruction is organized in six divisions: Agriculture, Arts and Sciences, Home Economics, Teacher Training, Business and Commerce, and Engineering. Associated with the resident instruction work of the college are the Storrs Agricultural Experiment Station and the Extension Service. The University is the Land Grant College of Connecticut and is supported from both Federal and State funds. The university is governed by a board of 13 trustees of which the state commissioners of education and agriculture are ex-officio members. Eight members are appointed by the Governor and two are elected by the alumni. The Governor is ex-officio head of the board.

ALBERT N. JORGENSEN,
President.

CONNECTICUT YANKEE IN KING ARTHUR'S COURT, a humorous tale by Mark Twain published in 1889. It is the story of a superintendent of an arms factory in Hartford, Conn., who one day lost consciousness from a blow received in a quarrel with his men, and when he awoke found himself in England at the time of King Arthur. The contact of Connecticut Yankeedom with Arthurian chivalry gives rise to strange results; yet amidst all the fun and pathos, the courtliness, the sincerity, and the stern virtues—as well as what seems to us the ridiculousness—of the age are well shown.

CONNECTIVE TISSUE, the most important supporting tissue of the body, derived like bone and cartilage from the mesenchyme of the embyro. It is made up of cells, which are relatively scanty, fibres and an intercellular ground substance secreted by the cells. The cells may be amœboid (in embryonic tissue), or may be the vacuolated so-called plasma-cells, or may assume a spindle-like or plate-like shape; and may contain pigment, granules of substance showing a peculiar affinity for certain dyes or fat. Besides these cells formed *in situ*, leucocytes often invade connective tissue. The white fibres of connective tissue are formed in bundles, are easily stained by acid fuchsin, yield gelatin on boiling, and are digested by artificial gastric juice, though not by pancreatin. The yellow fibres or elastic fibres, unlike the white branch and anastomose, are highly refractive, and during life, owing to the

tension under which they are, are straight. They are only slowly digested by the gastric juice, but rapidly by the pancreatic juice. Orcein acts as a specific stain for elastic tissue. The so-called reticulum is made up of fibres much like the white fibres, but not so easily attacked by artificial gastric juice.

Embryonic connective tissue is made up of spindle-shaped and amœboid, stellate cells, with few fibres and, in the less mature tissues, all of these white. The ground substance is fluid. Embryonic connective tissue is found not only in fœti and infants, but also in tumors and during the regeneration of injured connective tissue.

Gelatinous connective tissue occurs only in the umbilical cord and in the vitreous humor of the eye. It contains plate-like cells and reticulum, sparse in the vitreous humor and relatively dense in the umbilical cord. The ground substance is gelatinous.

Areolar connective tissue occupies all otherwise unfilled regions. The white fibres form interlacing bundles. The elastic fibres are isolated and comparatively few in number. The cells are of all varieties. The ground substance is a fluid which can be coagulated by silver nitrate.

Dense white fibrous tissue consists mainly of parallel bundles of white fibres with plate-like cells in their interstices. Yellow fibres are scarce and there is little ground substance. This tissue forms most tendons, ligaments, fascial and muscular sheaths, and envelopes many of the viscera. The valves of the heart, the chordæ tendinæ and the tendinous rings about the mouths of the great vessels are all formed from white fibrous tissue.

Elastic tissue is made up of bundles of elastic fibres with sheaths of white fibres. It contains but little ground substance. It is found in the ligamenta subflava dorsal to the spinal column and in the ligamentum nuchæ supporting the head in the lower mammals.

Adipose tissue is composed of cells distended until they have become mere sacs of fat and of fibrous bands supporting these cells. It is found beneath the skin of many parts of the body, about the lymphatic nodes, adrenals and kidneys, in the mediastinum and the grooves of the heart wall, and in the mesentery and omentum.

Reticular tissue is found as the stroma of many glands and in bone marrow. Its tissue juice is lymph. It consists of a reticulum of fibres closely joined in anastomosing bundles, with cells of a plate-like nature at the points of bifurcation.

Lymphoid tissue is reticular tissue permeated by the close-packed spheroidal lymphatic corpuscles. Lymphoid tissue is found in the tonsils, spleen, thymus, lymphatic glands, and in Peyers patches and the solitary follicles of the intestine. More diffuse lymphoid tissue is found elsewhere in the respiratory and digestive tract.

Connective tissues are richly supplied with blood vessels and nerves. They are nourished by the lymph exuding from the blood capillaries. The waste products of metabolism are taken up by the lymph capillaries.

CONNELLEY, William Elsey, American author: b. Johnson County, Ky., 15 March 1855; d. 15 July 1930. Though largely self-educated, he was for a number of years a school teacher in Kentucky and Kansas. He went to Kansas in 1881 and was county clerk of Wyandotte County, 1883–88. For four years (1888–92) he was in the wholesale lumber business, and then engaged in banking. His leisure was devoted chiefly to the study of the history and antiquities of the North American Indians, and the States of the Middle West. He compiled the first vocabulary of the Wyandot language, and made valuable studies of the languages of the Delawares, Shawnees and other tribes. He was secretary of the Kansas State Historical Society. His papers mostly appeared in the publications of the Ontario, Kansas, Nebraska and Ohio Historical societies, the Bureau of Ethnology and Smithsonian Institution. Some of their titles are 'The Provisional Government of Nebraska Territory' (1899); 'Notes of the Clan System of the Wyandots' (1899); 'Notes on the Folk-Lore of the Wyandots' (Journal of American Folk-Lore, 1900); 'James Henry Lane, the Grim Chieftain of Kansas' (1899); 'Kansas Territorial Governors' (1900); 'John Brown: the Last of the Puritans' (1900); 'The Overland Stage to California' (with Root, 1902); 'Doniphan's Expedition' (1907); 'Eastern Kentucky Papers' (1910); 'Life of Preston B. Plumb' (1913); 'History of Kansas' (1917); 'History of Kentucky' (1922); 'Indian Myths' (1928).

CONNELLSVILLE, Pa., city in Fayette County; alt. 890 feet; on the Youghiogheny River; 58m. SE. of Pittsburgh; on the Pennsylvania; Baltimore and Ohio; Pittsburgh and Lake Erie; Western Maryland; and Pittsburgh and West Virginia railroads. It was once the center of the most extensive coke-producing area in the United States, and until 1903 the coke output of this region was 40 to 50 per cent of the total output of the country. Coal and coke machinery, structural iron and steel, metal castings, glass containers, corrugated paper, silk, trousers, macaroni, and heaters are the main factory products. The Baltimore and Ohio has car shops here. At Broad Ford, just north, is a large and famous whiskey distillery. Boat-building was an important industry in the community's early days, as here the Youghiogheny River becomes navigable. Scottdale near by was the birthplace of Henry Clay Frick (q.v.), the first large-scale maker of coke. Connellsville was the scene of a violent miners' strike in 1891. Originally the site of a Shawnee Indian village, Connellsville was settled in 1770, and organized as a township. It was named in honor of Zachariah Connell, the founder, in 1793. Incorporated as a borough in 1806, it was chartered as a city in 1911. Pop. (1940) 13,608.

CONNEMARA, kŏn-nę-mä'ra, Ireland («the Bays of the Ocean»), a boggy and mountainous district occupying the most western portion of county Galway, about 30 miles long and 15 to 20 miles wide. The scenery of its broken coastline is very grand; in the sea inlets there is an abundance of fish; and there are numerous small lakes. It is subdivided into Connemara Proper in the west, Iar-Connaught in the south and Joyce Country in the north.

CONNERSVILLE, Ind., seat of Fayette County, alt. 828 to 910 feet, 59m. E. of Indianapolis, on the Whitewater River, and on the

Baltimore and Ohio, New York Central, and Nickel Plate railroads, and on three state highways. It lies in a hog- and corn-raising country, with good sand, clay, and limestone. Automobiles were formerly made here. Now the city makes trailers, trucks, auto parts and hardware, blowers, gas meters, metal and porcelain kitchen equipment, vacuum cleaners, caskets and casket hardware. Incorporated in 1813, it is governed by a mayor and a council. Pop. (1940) 12,898.

CONNERY, Thomas Bernard Joseph, American journalist: b. Ireland, 13 Oct. 1838; d. Atlantic City, N. J., 10 Feb. 1923. He was for years connected with the New York *Herald,* on which he held nearly every position except that of financial editor, 1856–84. He was editor of New York *Truth,* 1885; *Once a Week,* 1893–95; *Collier's Weekly,* 1895. He was United States secretary of legation and *chargé d'affaires* in Mexico, 1866–68. He was a member of the New York Board of Education in 1902. He published 'Don Tiburcio'; 'Black Friday'; 'History of American Comic Journalism'; 'Character Marks Autorial'; 'Essays on Literary Women of England'; 'All the Dog's Fault'; 'That Noble Mexican'; 'My Trip to Mars'; 'Violet Bland'; 'Forgotten Incidents: Lincoln's Visit to West Point'; also magazine articles.

CONNOR, Ralph. See GORDON, CHARLES WILLIAM.

CONNOR, Selden, American soldier: b. Fairfield, Me., 25 Jan. 1839; d. 9 July 1917; graduated, Tufts College, 1859; enlisted as a private in the 1st Vermont regiment 1861; became lieutenant-colonel of the 7th Maine regiment 1861, colonel of the 19th Maine 1864, and brigadier-general of volunteers June 1864. He was present at the battles of Fredericksburg, Gettysburg and the Wilderness, where he was severely wounded. After the war he held several minor Federal offices, was governor of Maine 1876–78, United States pension agent 1882–86, and 1897. On 3 Oct. 1889 he delivered the oration at the dedication of the Maine monuments at Gettysburg. In 1890 he became president of the Society of the Army of the Potomac, in 1896–99 was senior vice-commander-in-chief of the Order of the Loyal Legion, and in 1897 was again appointed pension agent, continuing in this office until the abolition by law of all pension agencies in 1913. His address on 'Hannibal Hamlin' was published in 1909.

CONODONTS (Gr. «cone-teeth»), minute fossils found in Palæozoic strata. They look very like the teeth of different kinds of fishes, some being simple slender pointed sharp-edged cones, while others are more complex, resembling in form the teeth of certain sharks. The old opinion was that they are minute teeth of fishes allied to the living hag-fishes and lampreys, but it is more likely that they are the jaws of annelids and naked mollusks. Consult Zittel and Rohon, 'Ueber Conodonten' (in *Sitzungsberichte der königlich-bayerischen Akademie der Wissenschaften,* Munich 1886).

CONOID, *in geometry,* a surface generated by a straight line moving parallel to a given plane in such a manner that it constantly touches a curve and a straight line; more generally, a surface generated by a line through two given straight lines and a given curve.

CONON, Athenian commander: d. after 392 B.C. Having been defeated in a naval engagement at Ægospotamos by Lysander, he for a time went into exile; but being aided by Artaxerxes, king of Persia, he returned and defeated the Spartans near Cnidus 394 B.C. Conon then began to rebuild the fortifications of Athens, and restored it to liberty and security.

CONON, of Samos, Greek astronomer and mathematician who lived in the 3d century B.C. He was a friend of Archimedes and invented the curve known as the Spiral of Archimedes. His works do not survive, but the main testimony to his genius is found in the laudatory comments in the surviving works of Archimedes.

CONQUEST, Ida (Mrs. Riccardo Bertelli), American actress: b. New York, June 1882. Her first stage experience was at the age of eight, when she appeared as Little Buttercup in the Boston Museum juvenile production of 'Pinafore,' a part she played over 300 times. Her professional début was made in 1894 as Constance in 'The Transgressor,' with Olga Nethersole, in Palmer's Theatre, New York. She had an ingénue part with the Empire Stock Company in 1896; and was leading lady with John Drew in 'Tyranny of Tears,' 'Second in Command' and 'Richard Carvel,' 1902; leading lady with William Gillette in 'Sherlock Holmes'; with Nat Goodwin as Helena in 'Midsummer Night's Dream,' 1903; starred with Charles Frohman in 'Girl with the Green Eyes,' 1904, and was leading lady with Richard Mansfield in 'Old Heidelberg,' 'Ivan the Terrible,' etc. She was leading lady with William Collier in 'On the Quiet,' 1905; appeared as Ann Whitfield in 'Man and Superman,' 1906, and later played in 'The Wolf' and 'A Little Brother of the Rich'; appeared with Nazimova as Asta in 'Little Eyolf,' 1910; and starred in 'The Talker,' 1911; after which she retired from the stage. She married Cavalier Riccardo Bertelli, of Genoa, Italy, 23 Oct. 1911. Others of her parts are Phyllis Lee, in 'The Charity Ball'; Carey, in 'Alabama'; Sybil, in 'The Dancing Girl'; Renée de Cochefort, in 'Under the Red Robe'; Consult Strang, 'Famous Actresses of the Day.' D. New York, N. Y., 11 July 1937.

CONQUEST, Right of. The appropriation of an enemy's territory by military occupation. In ancient times such occupation immediately passed title to the conqueror, but in modern times military occupation alone does not give such title to the invader. Title passes only when the invader manifests his intention of appropriating the territory by formal annexation, and when the acquiescence of the state from which it is taken shows the conqueror's ability to retain it. The Hague Conferences of 1899 and 1907 expressly detailed the rights and duties of the occupying power in 'Conventions Concerning the Laws and Customs of War on Land,' according to which the conqueror assumes ownership of all public property in occupied territory, and assumes the rights and obligations of the ousted state. The citizens of such occupied territory transfer their allegiance to the conqueror, although in modern times they are given the choice of leaving the territory if they refuse to swear al-

legiance to the new government. See DIPLOMATIC RELATIONS of the United States with the principal foreign nations; BELLIGERENT; WARS OF THE UNITED STATES.

CONQUEST OF MEXICO, The, a noted history by William Hickling Prescott, published 1843.

CONQUEST OF PERU, The, a history published by William Hickling Prescott (1847). Of the five books into which this work is divided, the first treats of the wonderful civilization of the Incas; the second of the discovery of Peru; the third of its conquest; the fourth of the civil wars of the conquerors; and the fifth of the settlement of the country. The first book hardly yields in interest to any of the others, describing as it does, on the whole, an unparalleled state of society. From the necessities of its material, the work is more scattered in construction than is the 'History of the Conquest of Mexico,' usually regarded as the author's most brilliant production.

CONRAD I, Emperor of Germany; d. 23 Dec. 918. He was elected king of Germany in 911; but Arnulf, Duke of Bavaria, and Henry, Duke of Saxony, disputed this title, and engaged the Huns to overrun Germany. Conrad, who was favored and supported by the Church, is said to have received a mortal wound in combat with these revolted chiefs, who were almost independent of the Crown, and the obedience of whom, therefore, Conrad was unable to command or win by other means. He is chiefly noteworthy for the revival in his case of the elective title to the crown.

CONRAD II, Emperor of Germany: b. about 990; d. Utrecht, 4 June 1039. He was the son of Henry, Duke of Franconia, and was elected king of Germany in 1024. Attempts were made to displace him, but without success, and in 1027 he was crowned emperor at Rome, in the presence of Canute, king of England, and Rudolph, king of Burgundy. He is regarded as the true founder of the Franconian or Salic line. He was often engaged in contests with the greater barons and princes of the empire, and endeavored to form a counterpoise to their influence by encouraging the formation of minor independent fiefs. With the same view he endeavored to appropriate several of the larger duchies to members of his own family, and thus convert the elective empire into a hereditary monarchy similar to that of France. These designs, though conducted with considerable ability, failed, mainly in consequence of the incessant contests in which he was engaged with the popes. He crossed the Alps in 1026, defeated the Italians and had himself crowned king of Italy at Milan. After a war which occupied most of the years 1032–34 he conquered Burgundy and made it a part of his empire.

CONRAD III, Emperor of Germany: b. 1093; d. Bamberg, Germany, 15 Feb. 1152. He was the founder of the house of Hohenstaufen; and was elected emperor in 1138. His title was disputed by Henry the Proud, Duke of Saxony, and the rivalry of these two princes was the germ of the factions afterward so famous under the names of Guelfs and Ghibellines. In 1146, at the Diet held at Spires, Conrad was persuaded by the eloquence of Saint Bernard to undertake a crusade, on which he set out the following year at the head of a large army. It was fruitless and disastrous, and Conrad returned with the wreck of his army in 1149.

CONRAD IV, Emperor of Germany: b. Andria, Italy, 25 or 27 April 1228; d. Lavello, Italy, 21 May 1254. He was chosen king of the Romans in 1237, but was never crowned; was a son of the great Emperor Frederick II. and like him excommunicated by the Pope. Innocent IV, who set up a rival emperor in William, Count of Holland. On the death of his father in 1250, Conrad marched into Italy to recover the towns which had declared against him. He took Naples, but could not get the investiture of the kingdom of Sicily from the Pope. In the midst of his troubles and contentions, he died of fever.

CONRAD V, or **CONRADIN OF SWABIA,** German prince: b. 1252; d. Naples, 29 Oct. 1268. He was the son of Conrad IV, and the last of the Hohenstauffen. He accepted the invitation of the Italian Ghibellines to place himself at their head and the sale of a large portion of his possessions enabled him to raise troops. In the autumn of 1267 he crossed the Alps with 10,000 men, and at Verona was warmly received by the Scala family, the chief of the Ghibelline party. His relatives here, persuading him to part with his remaining possessions at a low price, deserted him with their followers, leaving but 3,000 men. The Ghibellines, however, remained true to him. Verona raised a large army, Pisa a fleet, and Rome, whose pontiff was forced to flee to Viterbo, opened its gates to him. Conradin entered lower Italy, and at Tagliacozzo met the French army under Charles d'Anjou, on whom the crown of Naples had been bestowed by Pope Urban IV. He beat Charles back, and his men, supposing the victory won, dispersed in search of plunder, when they were attacked by the French and utterly routed, 23 Aug. 1268. Conradin escaped, but was betrayed into the hands of Charles at Astura, who caused him to be beheaded in the market place of Naples. His extreme youth, his unfortunate fate and the stories that clustered about him made him a good and favorite subject of poetry and more especially of the drama.

CONRAD, Charles M., American soldier and statesman: b. Winchester, Va., about 1804; d. New Orleans, La., 11 Feb. 1878. He went with his father to Mississippi, and thence to Louisiana while an infant, received a liberal education, studied law, was admitted to the bar in 1828 and practised in New Orleans. He served several years in the State legislature, was elected to the United States Senate as a Whig in the place of Alexander Mouton, who had resigned, and served from 14 April 1842 to 3 March 1843. In 1844 he was a member of the State Constitutional Convention. He was elected to Congress in 1848, and served until August 1850, when he was appointed Secretary of War by President Fillmore, serving from 13 Aug. 1850 to 7 March 1853. He was one of the leaders of the Secession movement in Louisiana in December 1860, a deputy from Louisiana in the Montgomery provisional congress of 1861, a member of the first and second Confederate congresses of 1862–64, and also served as brigadier-general in the Confederate army.

CONRAD, Frederik Willem, Dutch engineer: b. Delft 1769; d. 1808. He was the pupil and friend of Brunings, who did so much for the construction of the sea dykes of Holland, and on his death succeeded him in his situation of inspector-general of sea dykes in the province of Rynland. He afterward held the office of administrator-general of the sea dykes in the Low Countries. He rendered a lasting service to his country by reclaiming large tracts of land from the sea, and more especially by the formation of a proper outlet for the waters of the Rhine.

CONRAD, kōn'rät, **Johannes,** German political economist: b. West Prussia 1839; d. Halle, 21 May 1915. He was educated at the universities of Berlin and Jena. He was made professor of political economy at the latter institution in 1870 and at Halle in 1872. He was a member of the second commission appointed to revise the German Civil Code and took a prominent part in its deliberations. In 1878 he was appointed editor of the *Jahrbücher für Nationalökonomie und Statistik* and associate editor of the *Handwörterbuch der Staatswissenschaften* (1889–95; 2d ed., 1898 et seq.). He has published 'Das Universitäts-studium in Deutschland während der letzten fünfzig Jahre' (1884; Eng. trans. by Hutchison, with preface by James Bryce, 1885); 'Grundriss zum Studium der politischen Oekonomie' (1896–1909); 'Leitfaden zum Studium der Nationalökonomie' (1901).

CONRAD, Joseph, English novelist: b. Poland 1857; d. England, 3 Aug. 1924. He was educated in Cracow, and at 13 went to sea, becoming subsequently a captain in the merchant service. After a long experience as a sea rover, he settled in England and began putting his various experiences into literature. His writings include 'Almayer's Folly' (1895); 'An Outcast of the Islands' (1896); 'The Nigger of the Narcissus,' issued in America as 'The Children of the Sea' (1897); 'Lord Jim' (1900); 'The Inheritors' (with F. M. Hueffer, 1901); 'Youth and Other Tales' (1902); 'Typhoon' (1903); 'Mirror of the Sea' (1906); 'A Set of Six' (1908); 'Under Western Eyes' (1911); 'Twixt Land and Sea' (1912); 'Chance' (1914); 'Victory' (1915); 'The Shadow-Line' (1917); 'The Arrow of Gold' (1919); 'Rescue' (1920); 'Notes on Life and Letters' (1921); 'The Rover' (1923). Consult Aubry, G. J., 'Life and Letters' (1927).

CONRAD, Robert Taylor, American lawyer and dramatist: b. Philadelphia, 10 June 1810; d. there, 27 June 1858. He was mayor of Philadelphia and judge of the Court of Quarter Sessions (1856–57). He wrote 'Aylmere' (1852), a tragedy in which Edwin Forrest played the rôle of Jack Cade; 'Conrad of Naples,' a tragedy; 'Poems' (1852).

CONRAD, Timothy Abbott, American palæontologist: b. Philadelphia 1803; d. there, 1877. In his youth he followed the occupation of publisher and printer in his father's shop. He became interested in natural history, and published papers on marine conchology in 1831; and in 1832 began to publish in parts his work on the fossil mollusks of the Tertiary formations of North America, which was the beginning of systematic research in that department. He became State geologist of New York in 1837, and worked as State palæontologist from 1838–41, issuing during that time his serial monograph on the *Unionidæ* of the United States. It is upon this work and subsequent papers that his excellent fame rests. He finally returned to Philadelphia. Consult Merrill, in 'Report of the United States National Museum for 1904' (Washington 1906).

CONRADER, kōn'rä-dĕr, **Georg,** German painter: b. Munich 1838; d. 1911. He studied under Foltz and Piloty at the Munich Academy. He first came into notice with 'Tilly in the Grave-Digger's Dwelling'; On the Eve of Breitenfeld' (Kunst Halle, Hamburg). Other well-known and much-admired works by him are 'The Destruction of Carthage' (Maximilianeum, Munich), 'Hauer Painting Charlotte Corday in Prison,' 'The Death of Joseph II,' and portraits in the Budapest National Museum.

CONRADIN OF SWABIA. See CONRAD V.

CONRIED, Heinrich, American impresario: b. Bielitz, Austrian Silesia, 13 Sept. 1855; d. Meran, Tyrol, Austria, 27 April 1909. Graduating from the Oberrealschule of Vienna, he came to the United States, and was for several years a manager of German theatrical and operatic organizations. As director of the Irving Place Theatre, New York, he became known for excellent presentations of German classic drama, frequently repeated at Cambridge and other university centres. In 1903 he became director of the Metropolitan Opera-house, where he presented Wagner's 'Parsifal' for the first time outside Bayreuth. He resigned in 1908. Consult Moses, M. J., 'Life of Heinrich Conried' (New York 1916).

CONRING, kōn'rĭng, **Hermann,** Dutch scholar: b. Norden, East Friesland, 9 Nov. 1606; d. Helmstedt, Brunswick, 12 Dec. 1681. He studied at Helmstedt and Leyden, devoting himself chiefly to theology and medicine; was appointed in 1632 professor of philosophy at Helmstedt, in 1636 professor of medicine, and remained in this city until his death. He was distinguished in almost every department of knowledge, and the title of a councillor was conferred on him by the kings of Denmark and Sweden and the elector of the Palatinate. He was then made professor of law. The German emperor likewise distinguished him. From far and near his advice was sought in political and legal cases. He did a great deal in compiling the history of the German Empire, and improving German public law. He wrote 'De origine juris Germanici' (1643); 'Exercitationes de re publica Germanica' (1675); and very many other treatises to the number of over 100. His works, with his biography, were published in 1730. Consult Stobbe, also.

CONROE, Tex., county-seat of Montgomery County, 37 miles north of Houston; on the Int. & Gt. Nor. and Santa Fé railroads. It has lumber interests, and there are two negro colleges. Pop. (1940) 4,624.

CONSALVI, kōn-säl'vē, **Ercole,** Italian statesman and cardinal: b. Toscanella, 8 June 1757; d. Rome, 24 Jan. 1824. Having in 1797 entered the public service of the court of Rome in an humble capacity, he was four years later

one of the 12 auditors of the Rota, a commission in effect a supreme court of appeal in all matters secular as well as ecclesiastical. When the French took possession of Rome, Consalvi, falsely accused of having had part in an assassination, was for a while held in prison and then banished. When Pius VI died, Consalvi was largely instrumental in procuring, in the conclave held at Venice, the election of Cardinal Chiaramonti to the papal throne as Pius VII, and thereafter was that pontiff's chief counsellor; he was now second only to the Pope in all dealings with the European powers and specially with Napoleon. In the course of the controversies between Rome and the French emperor, he showed a firmness that won him the unwilling respect indeed of Napoleon, but also his irreconcilable enmity. It was while the Emperor was flushed with the victory of Austerlitz that he sent to Consalvi through Cardinal Fesch the message, "Tell Consalvi that if he loves his country he must either resign or do what I demand"; and the cardinal prudently withdrew from public life for a season. In 1809 he had an interview with Napoleon at Paris, in which the Emperor in effect made an apology for that act; but Consalvi persisted in his opposition to Napoleon's designs; and was one of the 13 cardinals who refused to concede the lawfulness of the second marriage of Napoleon. In punishment of his obstinacy in that matter he was held in confinement three years at Rheims. After the fall and banishment of Napoleon, he resumed his station in the papal court and devoted himself to the institution of many reforms in the government, being in effect chief governor of Rome and the papal states. He was always a liberal patron of art, literature and science. He left the bulk of his property to the poor. Consult Crétineau-Joly, 'Mémoires du Cardinal Consalvi' (Paris 1895).

CONSANGUINITY, relationship of persons descended from the same ancestry or common stock. Consanguinity may be either direct (known also as lineal) or collateral. Consanguinity is direct when the relationship is that which exists between ascendants and descendants, as grandfather, father, son. It is collateral when the relationship is that which exists between persons who have the same ancestor but who are the issue of different children, as first cousins. Various degrees of consanguinity are recognized by law, but the manner of computing collateral consanguinity varies with the locality, depending on whether the civil or the canon law is followed. In the civil law the degrees from the common ancestor are numbered on both sides, brothers thus being related in the second degree and first cousins in the fourth. In the canon law, which is the same as the common law in this particular, the steps between the remoter person and the common ancester are counted, brothers thus being related in the first degree and first cousins in the second degree. The rule for computing the degree of lineal consanguinity is the same for the canon, civil and common law. English law and the law of most of the States in this country follow the canon law in reckoning downward from a common ancestor. Consanguinity is an important question in the law of marriage, inheritance and descent, certain crimes as incest, and in determining the disqualifications of judges, jurors, etc. The term consanguinity must be carefully distinguished from affinity, which latter term means relationship by marriage, either through the husband or wife, and not through a common ancestor. See Descent in Law; Inheritance.

CONSCIENCE, kôn-syäns, **Hendrik,** Belgian novelist: b. Antwerp, Dec. 3, 1812; d. Brussels, Sept. 10, 1883. He was mostly self-educated. He entered the army in 1830 but resigned in 1836 and in the following year published his first novel in Flemish, *In the Wonderful Year 1556.* It was a great success but the author was left under a burden of debt to his printer. *Phantasy* and *The Lion of Flanders* followed soon after. Conscience was one of the first to use Flemish as a medium of literary expression and his example heartened others, who had less patriotic courage, to do likewise. It also secured for him a measure of government patronage, being granted a post in a government office. He abandoned this for gardening and soon afterward was appointed to a post at the Royal Academy of Painting. In 1845 he was made associate professor at Ghent and instructor in Flemish to the royal children, and in 1868 became custodian of the Wiertz Museum. He published in all over 100 volumes and the occasion of the publication of his 100th volume in 1881 was made a national celebration. His historical novels are inferior to his works dealing with Flemish home life, which he knew. In addition to those noted above his most noteworthy works are *How One Becomes a Painter* (1843); *Poor Nobleman* (1851); *The Good Luck to be Rich* (1855); *Duke Carl's Justice* (1876); and *Benjamin of Flanders* (1880). (See Lion of Flanders, The; Rikki-Tikki-Tak). Consult the biographies by Eeckhoud (Brussels 1881) and Pol de Mont (Haarlem 1883).

CONSCIENCE, the mental basis of our judgments of moral obligation. The conscientious examination of a course of action consists in: (a) the fullest possible inquisition into the motives, results and other bearings of the action; (b) the approval or disapproval of the entire course of action in the light of this inquisition. The act of approval or disapproval does not appear to be essentially different in character from that involved in judgments of taste or pleasure or the dicta of prejudice. It is the vastly wider scope of the preliminary examination, together with the fact that its judgments are most usually concerned with conduct and its principles, which mark conscientious judgments off from all others of a normative nature. See Ethics; Norm.

CONSCIENCE MONEY, stolen or wrongfully acquired money returned to its rightful owner when conscience is awakened to a sense of right dealing. In the United States such money paid into the treasury at Washington by self-avowed debtors anonymously is known as the conscience fund. In England the phrase is applied to money forwarded, as a rule anonymously, to the Chancellor of the Exchequer for unpaid income tax. It amounts to some thousand pounds a year.

CONSCIENTIOUS OBJECTOR, a conscript who declines to perform military service on the ground that the state has no right to require it of him. Humanitarian, moral or religious principles are generally advanced as the reason for the objector's refusal to serve in the armed forces of his country. The Religious Society of

Friends (Quakers) since their foundation in the middle 17th century have held it a cardinal tenet to abstain from warmaking or participation in any warlike preparations. This prohibition of military service did not, however, prevent a considerable number of Pennsylvania and Long Island Quakers from volunteering in the Revolutionary Army and the Union Army during the Civil War. Another sect, the Mennonites, German and Dutch dissenters, who were given asylum in William Penn's proprietary province in the late 17th century and founded Germantown, profess similar nonresistant principles. The Doukhobors, who found refuge in Canada in 1899, were expelled from Russia principally on account of their religious objection to military service.

The large number of conscientious objectors in England during World War I brought the problem to public notice. Special tribunals were established to deal with them. Some were transferred into noncombatant units and others into war work and agriculture. Many others were given prison sentences. In 1918 an act of Parliament was passed disfranchising any conscientious objector who had refused to perform the service assigned him for a period of five years after the war.

During the same conflict conscientious objectors in the United States presented a like problem to the civil and military authorities, despite the fact that the conscription bill made liberal provisions for recognized sects, such as the Quakers and Mennonites, whose creeds opposed bearing arms. These religious objectors, however, were not exempt from the draft; they must serve but could choose a noncombatant corps. A distinction was drawn between "sincere" and "insincere" objectors. The former were given the choice of agricultural service or serving with the Friends' and Red Cross units in France. The "insincere" objectors were those who professed no religious or moral antipathy to war, but refused to fight against Germany. The men in this category, for the most part of German birth or descent, were court-martialled and given prison sentences of short duration. In November 1920 a group of 31, the last of the imprisoned objectors, was released, only two years after the end of hostilities.

United States government reports of World War I conscientious objectors (popularly termed "Conchies") indicate a surprisingly small number, a total of only 3,989. Of these, 1,300 accepted noncombatant service; 1,299 were furloughed for alternate service; 450 were imprisoned by court-martial; and the remainder were in camp at the time of the armistice.

During World War II conscientious objectors were far more numerous in the United States, and a much greater number were imprisoned. However, they constituted only a minute fraction of the drafted men. On Jan. 6, 1943, the Selective Service System in Washington reported that of more than 5,000,000 conscripts only 6,277, about 0.1 per cent, were in this category; and of these 40 per cent were Mennonites. Among other religious objectors were members of the Moral Rearmament Movement, an outgrowth of the Oxford Group which preached pacifism in the period immediately preceding the outbreak of the war. The number of British conscientious objectors was both actually and relatively larger than in the United States, numbering 52,000. Nearly half of these (24,000) were allowed to enter war work. Nine months after the war ended (May 1946) some 2,600 American conscientious objectors were still held in federal prisons.

CONSCIOUSNESS, properly an abstract term which, like "happiness," "graciousness," or "thoroughness," refers to some quality of the human being taken *in abstracto*. However, the hypostatizing tendency of human thinking has led to its use as if referring to something existential. Since a man may be conscious, it is easy to fall into the assumption that he may have consciousness, then that something like a consciousness exists. This tendency to hypostatization has been strengthened by another circumstance. Much psychological interest has been in the description of one's experiences when he is conscious, his feelings, perceptions, emotions, thoughts; and to arrest such experiences in midcareer, to hold them static for detailed description, incurs the danger of misapprehending these cross-sectional snapshots as stable and enduring things.

The term "consciousness" has been used in a variety of meanings. The two most technical uses may be mentioned. A person is conscious so long as his mental processes are going on, and unconscious as soon as these ideas, thoughts, feelings, and so on, are in abeyance. "Experience," "awareness," and "consciousness" then mean the same thing. A more recondite use is where consciousness means a person's awareness of his mental processes, the immediate knowledge which one has of his sensory and affective and ideational processes. We shall neglect the second, and expand the first. There are degrees in this being conscious, varying from the total absence of anything—or at least the total absence of anything recallable later—of a coma, to the keen and lively alertness of one sensing danger. A low degree of being aware is characterized by vagueness and fluidity; a high degree by focalized attending with all its clearness and vividness.

How can one describe, compare, and formally break down his experiences? To ask, "What is it like to be conscious?" is to word an impossible question, for, as is true in blindness, unless one has had the experience firsthand no verbal statements can acquaint him with it. One can, however, recall and compare the different things of which he has been conscious and the different ways in which he has been conscious of them. Psychologists called structuralists have applied themselves to this analytic work by *introspecting*. Awarenesses of present things break down, if we are analytic and atomistic enough, into quales derived through the senses. These may be differentiated into modalities—visual, auditory, olfactory, gustatory, cutaneous, kinesthetic, static, and organic; and experiences within any of these groupings vary further as to their intensity, extensity, duration, quality, and clearness. Not only may one be aware of things present in these ways, but he may be aware of things absent, he may have imagery; and the same dimensions of variation again apply. What one is conscious of, the so-called contents of consciousness, includes then all these variable experiencings but combined and rearranged in countless ways, ranging from chance conglomerations of drowsiness or reverie to the neat sequences of logical thinking. The combining and rearranging are

not themselves, however, ordinarily experienced, but only their results.

The question of how this being aware, or consciousness, is related to man's other biological processes is difficult of answer. Evidences from embryology, comparative anatomy, and pathology, point clearly to some correlation with neural functions, particularly of the master ganglion, the cerebrum; for complexity of development, as well as healthy integrity of his cerebral structure, seem to go with ability of a person to report that he is conscious. Injure the head and the cerebrum and your victim apparently loses all consciousness or is conscious of only some particular kinds of things. The muscular system cannot be ignored, however, in any inquiry into the organic correlates of being-conscious; and there is some evidence even for the dependence of one's thought-play upon the delicate changes in his complex motor apparatus. The stream of consciousness, the sequences of things of which the conscious man is aware, is then a complex composite of experiential elements derived not only through the exteroceptive sense organs but also from the interoceptive sensory channels flowing back from the muscles.

A less descriptive and more functional treatment of consciousness appears in the psychoanalytic use of the term. In disentangling the complex motivations of men to unravel the peculiarities of their everyday behavior as well as the why's of their neuroses, Freud found that it is useful to assume three levels of awareness: the conscious, the foreconscious or preconscious, and the unconscious. Immediately below the level of full consciousness lie the preconscious ideas of which one is not aware at the moment but which he can recall to mind more or less readily. Then there are ideas or motives which quite resist any recall under ordinary circumstances, and which—to continue Freud's spatial analogy—lie in the great unconscious. The inaccessibility to the individual's recall of these ideas is due to their strong incompatibility with his conscious thoughts and ideals; and it is as if a powerful censor—owing its nature to his established thou-shalts and thou-shalt-nots—were acting to suppress and repress them, and so to protect the individual personality from the disruptive effects of his realizing them.

The term "subconscious," which is not to be confused with any Freudian meanings, has been much employed in the study of phenomena in which a man's thinking operations produce certain products without his being aware of the process as going on. Examples are: the crystal gazer's recall of things he was not aware of having seen before; the mathematician's or the poet's sudden awareness of an answer to a problem he thought he had put quite out of mind; the faithful following of an instruction given the hypnotized subject, but performed some time after the trance is lifted and without any recognition on the performer's part that it was an instruction. Such operations, being outside the person's consciousness, are often called subconscious operations. The great danger there is the ready assuming of a "subconscious mind," a daimonlike agency to which all sorts of mysterious powers are popularly attributed. It makes for clearer thinking to insist upon use of this word (as in the case of "conscious") in its attributive rather than in any substantive sense. See also PERCEPTION.

JOHN FREDERICK DASHIELL,
Kenan Professor of Psychology, University of North Carolina.

CONSCIOUSNESS, Biological Aspects of. Apart from subtle metaphysical or abstract psychological distinctions we shall arbitrarily conceive of consciousness as that controlling mental institution which directs life's energy for the production of useful work, the word "useful" being used in an extremely broad sense. Just how consciousness grew out of tropisms, what its subtle distinctions may be from reflexes, what are its relations to the unconscious, these are matters which for the present lie outside of this discussion. It is here assumed that consciousness is a higher evolutionary product, assuming greater and greater control and precision as the opportunities and needs for adaptation to reality grow in the advancing animal scale. That consciousness may still be made a better and better instrument for analysis of and adaptation to reality goes without saying.

Adaptation to reality is a complex function of the cerebral mechanism and we may follow Bergson in saying that it is through both instinct and intelligence that this takes place. In intelligent or logical activities consciousness is assumed. Is there a consciousness in instinct? This question brings one back to the matter of tropisms, of reflexes, and of the unconscious. To present this latter problem Bergson assumes two kinds of unconsciousnes, one in which consciousness is an absent factor and one in which consciousness is merely nullified. As he says both are equal to zero, but in one case zero expresses the fact there is nothing, in the other that there are two equal quantities of opposite sign which compensate and neutralize each other. Thus one may speak of the unconsciousness of a falling stone. Instinct however has a different type of unconsciousness. When one performs an habitual action, when a somnambulist automatically acts out a drama, as did Lady Macbeth, unconsciousness may be absolute and yet of what does it consist. Bergson holds with reason that the representation of the act itself resembles the idea so perfectly, and fits it so exactly, that consciousness is unable to find room between them. Freud, Jung and Bleuler would speak of this as a special kind of thinking in which the Ego represents the painful ideas from consciousness. Consciousness is suppressed into unconsciousness. Fantasy thinking or autistic thinking results. The dramatization is the action and as Bergson shrewdly notices the representation is stopped by the action. As proof this latter author

calls to mind the fact that if the accomplishment of the act is arrested or thwarted by an obstacle consciousness may reappear. It was there but neutralized by the action which fulfilled, thereby filled the representation. This inadequacy of act to representation is what Bergson calls consciousness. He is worth quoting further on this point since much of the knowledge of psychopathology gained by psychoanalysis tends to confirm a part of his attitude. If this point be examined more closely, it is found that consciousness is the light that plays around the zone of possible actions or potential activity which surrounds the action really performed by the living being. It signifies hesitation or choice. Where many equally possible actions are indicated without there being any real action (as in a deliberation that has not come to an end), consciousness is intense. Where the action performed is the only action possible (as in activity of the somnambulistic or more general automatic kind), consciousness is reduced to nothing. Representation and knowledge exist none the less in the case if a whole series of systematized movements are found, the last of which is already prefigured in the first, and if, besides, consciousness can flash out of them at the shock of an obstacle. From this point of view, the consciousness of a living being may be defined as an arithmetical difference between potential and real activity. It measures the interval between representation and action.

It may be inferred from this that intelligence is likely to point toward the conscious, and instinct toward the unconscious. For, where the implement to be used is organized by nature, the material furnished by nature, and the result to be obtained willed by nature, there is little left to choice; the consciousness inherent in the representation is therefore counter-balanced, whenever it tends to disengage itself, by the performance of the act, identical with the representation which forms its counterweight. Where consciousness appears, it does not so much light up the instinct itself as the thwartings to which instinct is subject; it is the deficit of instinct, the distance between the act and the idea that becomes consciousness, so that consciousness, here, is only an accident. Essentially, consciousness emphasizes only the starting point of instinct, the point at which the whole series of automatic movements is released. Deficit, on the contrary, is the normal state of intelligence. Laboring under difficulties is its essence. Its original function being to construct unorganized instruments, it must, in spite of numberless difficulties, choose for this work the place and the time, the form and the matter. And it can never satisfy itself entirely, because every new satisfaction creates new needs. In short, while instinct and intelligence both involve knowledge, this knowledge is rather *acted* and unconscious in the case of instinct, *thought* and conscious in the case of intelligence. Before discussing this subject further a glance at the organs in which these mechanisms are concentrated may aid in fashioning a workable concept.

Cerebral Localizaton.— The general biological principle of the concentration of energy as a feature of advanced evolutionary development finds its expression for the psychical sphere in the more or less distinct localization of definite functions to certain portions of the brain.

For the purely vegetative activities such localization is as yet indefinite, but it is known that the areas governing the various members are accurately located. The important sense organs also show a like integration, and the localization of so-called centres for sight, hearing, smell and motor speech now admits of little question.

It is, by more or less common consent, based on general grounds, as well as on the data afforded by physiological experiment and pathological observation, as well as by the study of the comparative psychology of the lower animals (by Darwin, Herrick, Thorndike and Kappers et. al.), that the higher mental processes (i.e., those that are more complex and those which have developed late in the evolution of the race) utilize the frontal lobes of the brain in their activities; but it is certain that, so far as the ego is concerned, taken in its totality, no such localization can exist. The whole body is a psychical organ, and the sense of the ego depends on such a multitude of sensory impressions that its location is coexistent with the nervous system in its totality. It is to be borne in mind that the complex nexus of associational fibres should be considered constant factors in the idea of a consciousness. The great modifications that occur in consciousness — due to the cutting out of action of certain of such associated fibres — is a constant feature in certain hemiplegic states, and probably some similar pathological entities lie at the foundation of some of the modifications of consciousness in some of the psychoses, notably general paresis.

Within recent years the labors of the histopathologists have brought into prominence the importance of minute structural changes of the connections of the various nerve processes; collaterals, axis cylinders and dendrites, forming plexuses of communication between various systems of nerve-cell groups. Such changes are closely correlated and are probably direct causative agents of many of the symptoms of mental disease, such as loss of attention, diminished initiative, amnesia, blunting of the higher ethical ideas, insomnia, and many of those psychical activities which modify conduct so largely, and hence are representative of the personality.

From such a purely preliminary sketch it can be seen that it is futile to attempt to speak of a localization of consciousness as if such a faculty were a thing *per se* rather than a function of psychical nerve activities.

Connected, however, with this question there are to be considered certain localizations of some of the more clearly defined psychical activities.

Evidence derived from the lower animals points to the fact that following the cutting out of the prefrontal lobes there is more or less mental degradation. Close attention is lost, and observation which looks for the safety of the animal is often notably affected. Attention, judgment, memory and notably inhibition are parts of the personality which are modified by disease or injury to the frontal lobes, and with such are associated hesitation, fear, uncertainty and motor restlessness due to impaired inhibition.

Studies of monsters without a brain have shown that without a cortex, but yet possessing enough of the cerebrospinal mechanisms to bring spino-thalamobulbar fibres into play, many automatic activities may take place, notably sucking. Goltz's celebrated decerebrate dogs and the later studies of Rothmann also have shown that highly complex reflex activities may be carried out by these pallium-minus dogs. Hence one may say that certain instinctive activities persist but no intelligent ones. In these instinctive activities there is that type of unconscious already spoken of as represented by the absence of consciousness. The thwartings to which the instinct is exposed prevent conscious awareness. Consult Fulton, 'Physiology of the Nervous System' (New York 1938). See CONSCIOUSNESS; CONSCIOUSNESS, DISORDERS OF.

SMITH ELY JELLIFFE.

CONSCIOUSNESS, Disorders of. There was a time in the history of psychology when consciousness and its opposite were spoken of as faculties, as static entities and thus described. An elaborate series of forms was created and given semantic individuality. Thus Ribot's classic on 'Disorders of Consciousness' was possible. At the present time his work is better named Disorders of the Personality and consciousness *per se* is but one aspect of the personality. In Bergson's very apt phrasing, «the cerebral mechanism is arranged just so as to thrust back into the unconscious most of our past and allow beyond the threshold only that which will aid the work in hand.» In Freudian terms that threshold is the boundary between the conscious and unconscious being held in dynamic balance by that mental institution called the «Ego.» In older terms, conscious awareness is that which gets through from the vast storehouse of experience of life since the beginning: i.e., a billion or more years of «knowing» in an experiential sense, even if but a million or more in the sense of intelligent awareness, which in the «higher» animals is capable of verbalization.

Thus various names are given to the varying kinds of behavior related to the nature of the balance between dynamic acting wishes and the repressing forces of the Ego institution of the cerebral mechanism. There is a gamut of behavior from the blotto of death, or of intoxication, running through the dream, dreamy delirium, delirium of euphoria, ecstasy to controlled creative activity. The world's literature may be ransacked to find the infinity of variations in human behavior, and termed good or evil, well or sick, according to the time and place and surrounding mores. The mescalin intoxicated priest carrying out an Indian ritual is adapted and healthy according to the rules of the game. Under other circumstances and in other places his behavior would probably bring him confinement in the police station or in a mental hospital.

Thus the classification of disorders of consciousness may be considered a nominalistic fiction which has practical value, according to the situation. The important issue is the balance between the forces leading to action of human cravings, impulses, drives, instinctive needs or wants, call them by as many different names as one will, and those forces (repression), functions of the mental institution here called the «ego,» intelligence of the older faculty psychologies, what emerges, in the Bergson metaphor already cited, is adapted or maladapted behavior, so-called normal or abnormal, healthy-physiological or diseased-pathological, sometimes requiring a legally circumscribed procedure to determine which is which.

The older category of exalted, depressed or perverted states of consciousness is outmoded. It has no relevancy to what may be thought of as clinical entities in psychiatry. In fact the whole concept of disorders of consciousness is useless, since in a dynamic psychology consciousness is not a static entity. It is a phasic series of interactions which require other factors to be included in the conception.

The disorders of Ribot's day are here more or less tentatively followed.

The disorders of consciousness for the present purposes are broadly divided into a few general groups. There are: (1) Disorders of sleep and the allied phenomena; (2) disorders of the neuroses and psychoneuroses, including the phenomena of automatism, double personalities, amnesia, etc.; (3) the intoxications; and (4) the psychoses. Such a classification is manifestly incomplete and imperfect. Thus many of the phenomena of groups (1) and (2) are interchangeable. It is moreover popular at the present time to attribute most of the physical ills to various toxæmias, either autogenous or heterogenous, and it is certain that no hard-and-fast line can be drawn clinically between certain maniacal states due to intoxication and those of a purely psychical etiology. In the present changing conditions of psycho pathology the question of categories is an academic one after all.

(1) **Disorders of Sleep and Allied Phenomena.** — (Dreams, Somnambulism, Trance, etc.)

Somnambulism.—The simplest type of such fantasies is found in some somnambulistic states. In these the individual may perform, while still asleep, many of the simpler acts of the waking state, and indeed even many extremely complex acts are carried to completion. The patient awakes without any conscious recollection of the acts performed, and often such acts have been harmful to self and society.

The clinical phenomena are not constant. The eyes are frequently closed or semi-closed, or even wide open and staring. The pupils are apt to be sluggish in their reactions, but may be normal in diameter, dilated or contracted. The data collected by Gould and Pyle ('Anomalies and Curiosities of Medicine') may be referred to by those who would learn more of the complicated motor acts that many notable cases have been known to perform. Suicide and homicide have been committed by persons in the somnambulistic state. The somnambulistic state is recognized to be a special instance of autistic or fantasy thinking. The patient acts his unconscious fantasy, often with evident, but more often with complex and veiled, symbolisms. Association experiments and psychoanalysis seem to prove that the experiences lived during the somnambulistic state may be brought to consciousness. Some register is made in consciousness since a memory of them may be awakened. This does not mean that the individuals have a knowledge of what they were doing at the time it was done. This commonplace of medical science is one of the stumbling blocks of law, where the ignorance of lawyers has given rise to the stupid and

unjust definition of "responsibility." Somnambulistic performances carry out the general trend of the unconscious, i.e., toward fulfilment of instinctive desires.

Nightmare.— This is a painful dream state. In many instances, where such are extremely distressing, they have been known to precede grave cerebral disturbance, but it is not certain that they have any close relationship with the same, save perhaps in certain types where the fear of death appears in symbolic form. The more recent studies of Freud, Jones and others have pointed the way to a better hypothesis of these nightmares. They are discussed more fully in the article on DREAMS.

Lethargy, Catalepsy, Trance.— These are terms used to describe atypical unconscious states which are as yet imperfectly classified, partly on account of the fugitive character of the alterations and partly because of the complications of the picture with other symptoms of the hysterical and epileptic conditions. The phenomenon of hypnotic sleep is best put in this category.

In catalepsy the prevailing phenomenon consists of the wax-like rigidity which the limbs can be made to assume, at times unconsciously; again, especially in the hypnotic condition, by the suggestion of the operator. In trance conditions there may be manifest a great variation of phases, most of which are accompaniments of the hysterical state. All of these phenomena which occur in a variety of the psychoneuroses as well as in the psychoses, cataleptic states, lethargies, trances, etc., being extremely frequent in hysteria and more particularly in catatonic types of schizophrenia (dementia præcox), have been much better understood, thanks to Freud's ingenious hypotheses. They all represent, as stated, wish-fulfilling fantasy dramatizations, the precise significance of which can be laid bare by the principles of psychoanalysis.

(2) **Disordered Conscious States in the Neuroses and Psychoneuroses.**— No sharp dividing line separates the neuroses from the psychoneuroses so far as the prevailing disturbances of consciousness are concerned. Here under the neuroses are considered neurasthenia and anxiety neuroses, while hysteria and the compulsion neuroses (morbid phobias, fears, compulsion ceremonials, etc.) are here termed psychoneuroses. For neurasthenia, the chief phenomena are fatigue states, anxiety states in the anxiety neuroses, conversions of psychical unconscious states into physical phenomena (blindness for not willing to see, deafness for not desiring to hear, paralysis from fantasies of various kinds, etc.); indeed the whole gamut of somatic signs of hysteria may be mentally reviewed by the reader as falling under the formula conversion. Finally in the compulsion neuroses there is an erection of psychical defenses which show the phenomena of substitution. Here the sources of the emotion in the unconscious are transferred or displaced to some irrelevant matter which comes to symbolize in a specific manner the nature of the unconscious, suppressed emotional situation.

In many *neurasthenic states* organic factors loom large in determining the feelings of fatigue in consciousness. Others again, however, are purely emotional in their development and here conscious and unconscious processes are in rivalry. The desire to be sick to escape obligation; the reversion to indolence unconsciously is a large motive. The libido, that is, the energy of these individuals, concerns itself with their own bodies and they live, in fantasy, as neurasthenics, the life of the cared-for and nursed child. Here unconscious fantasy helps to disguise the task — that is, to be independent captains of their own destinies.

In the *anxiety neuroses,* physical states are also present, such as flutterings, tremblings, gaspings for breath, air hunger, very frequently palpitation, fear of impending death, anxiety lest something may happen to self, to others or to material welfare, diarrhœas, mucous colitis, gastric irregularities of all types, etc. These make up the physical signs induced by the unconscious fantasy, largely of temptation. These patients are constantly repressed; they suffer from suppressed excitement and the symptoms mentioned constitute the outlet for the repression, the exact nature of which is veiled behind the symptom, not as a true conversion as in the hysterical mechanism, save in certain mixed anxiety hysterias. Freud and Stekel as well as many others assume that this type of disorder is found more particularly in those who find the demands of culture too arduous, and yet whose ethical attitude refuses to face a certain, often but not invariably a sexual, situation. Unrequited affection, dissatisfaction with life's sternness, actual sexual stimulation without gratification — as in coitus interruptus, coitus reservatus, menopause, artificial and natural — unconscious temptations toward dishonesty, hateful impulses repressed from consciousness — these are among the dynamic factors bringing about these peculiar modifications of conduct to meet these situations.

In *hysterical conversions* the mechanisms are more complex. Here the complexes play a more determining rôle and the cast-off and yet still retained complex is more precise and definite.

Thus the essential factor, so far as consciousness is concerned, is dissociation which, according to the original view as held by Janet, is due to an inborn weakness, namely, some factor in the constitution of the individual which predisposed him to this type of reaction. Hence, by the French school, and by those who followed Janet's teachings, the search for this inborn factor was made chiefly in the prenatal life of the individual, namely in heredity, and unfortunately as a correlate of such teachings a pessimistic attitude toward therapy was inevitable. The chief advance made in the hypothesis formulated by Freud was that the factor bringing about dissociation was not so much to be sought in heredity as to be looked for in the psychological dynamics of the nervous system, so that, for reasons which psychoanalysis has revealed, a certain group of ideas or complexes remained in the unconscious, but were still active. Hence arose the concept of repression as worked out by Freud.

Inasmuch, however, as the dynamics of the nervous system could not be interfered with, some form of expression of energy must take place. The repression acting upon this discharge of energy brings about the process of conversion, that is, there is a motor discharge but the repression distorts it — puts a different

face upon it, so that the patient carries out the unconscious repressed wish in a form of dramatization known as the symptoms of the disease.

This dramatization, concerning which a much more extended discussion will be found in the article on hysteria (q.v.), presents a number of distorted mechanisms which a study of the dream life has made clear. These distorting mechanisms permit the living out of the wish, at the same time that it remains practically unconscious. Mixtures of conscious and unconscious fantasy are present in practically all hysterical attacks, so that they present various combinations.

Compulsion Neuroses.—Here the unconscious factors are handled in a manner somewhat different from that seen in hysteria. Under this head is usually included a large number of obsessive, phobic and compulsive ideas which represent an unsuccessful repression of the psychosexual conflict. Unlike hysteria, the conflict is apt to come into consciousness; it cannot be entirely disguised by the distorting mechanisms. Conversion is not so frequent a phenomenon, but instead another type of reaction is met with, namely, substitution. By this is meant that the repressed conflict, breaking into consciousness, does not come into consciousness in its true light, but is immediately transferred or transposed, that is, substituted, upon something that is innocuous. A common illustration from every-day life illustrates in part this mechanism. Thus, an irritable husband with a burden to carry, immediately on sitting down to breakfast, complains about the coffee; notwithstanding the fact that the coffee may be the same that he has been drinking for 15 years, on this particular morning it is atrocious. Here the psychical disturbance, the discomfort, the irritability is transposed or substituted upon the innocuous object, and one that has nothing whatever to do with the original source of irritation, but serves as a carrier or outlet for it. Thus the phobia, the compulsive act, the obsession becomes the innocent object for the expression of the emotional or complex disturbance of the patient. Thus, a patient will be unable to look upon a negro, will refuse to go out of the house without securing the door a number of times, or may have to put white papers under the beds, or in dark closets, have to look at people two or three times to be persuaded that they are not negroes, and a complicated ceremonial grows up about the question. The negro is only a symbol and behind the symbol lies the original difficulty.

To understand the activities of the unconscious in the compulsion neuroses is very difficult, but perhaps the most illuminating hypothesis that has been utilized for the explanation of these phenomena is that of Freud. He assumes that the fairly developed neurosis, say of a person of from 25 to 35, or even 40 years of age, represents the terminal stage of a complicated series of phenomena. The initial stage is usually laid down in childhood where, as a reaction to infantile attitudes, usually of a nature to satisfy sexual curiosity, then not known to be sexual, the patient comes to a sense of guilt concerning these activities. This sense of guilt is usually overcompensated for by little manifestations as it were of overgoodness. The children become very punctilious, very fond of their parents, intensely religious or intensely self-sacrificing, do everything they can to be good, which is hardly the normal state of childhood. They are compensating for something which needs to be compensated for apparently, and the compensation aids in pressing memories of the early experiences or fantasies into the unconscious. It may be that this overcompensation is effective, as it frequently is in mystics, religious enthusiasts, zealots, reformers, extremists and cranks of various kinds, but not infrequently the overcompensation breaks down, the original fantasies which have been put to sleep reawaken now with a much stronger imperativeness, and immediately a conflict arises, whereby the demands of the original instincts of gratification can be accomplished, and also whereby the demands of a cultural attitude may be maintained. A ceremonial which represents these conflicting tendencies develops whereby the patient can keep his cake and eat it too. The mask that is worn is of various types, as any one who has had a large experience with compulsion neuroses can testify. Sometimes an overdetermined symbolism may in the course of time become extremely complicated. The patient is driven from one level to another, and in the search for rest lights upon a series of islands of safety as it were, to be away and have to search for a new one. Thus successive lines of defenses grow up, and in every old compulsion neurosis the unraveling of the various lines of defense becomes an extremely difficult matter.

CONSCIOUSNESS IN ANIMALS. See ANIMALS, MIND IN THE BRUTE.

CONSCRIPTION. As defined by Colonel Maude, English soldier and scholar, conscription is «the selection by lot or otherwise of a proportion of the men of military age for compulsory service in the naval and military forces of their country.» It is the underlying principle involved in the concept of the «nation in arms,» reborn in the French Revolution of 1793 after lying dormant for 14 centuries. With today's advent of total war, as conducted by the dictators of Europe, Colonel Maude's definition must be widened to cover the induction of all individuals, female as well as male, into any service or industry deemed essential by the government to the prosecution of the war. Japan provides the Oriental replica with its National Mobilization Law of 1938.

The origin of the term is found in the Latin expression *conscribere milites,* referring to the enrolment or registration of men chosen for the legion from the whole body of freeborn Roman citizens capable of bearing arms. However, the initial employment of the idea antedates civilization by untold centuries. The instinct of self-preservation taught prehistoric man to band together for self-defense and aggression. In the day of H. G. Wells' «old man,» no able-bodied male was exempt from such service; in fact, the man of subnormal physique was «liquidated.» Thus, in its essence, military conscription is undoubtedly the oldest form of co-operative human effort.

Ancient Times.—With the dawn of civilization, conscription became the general practice for the peoples who achieved their day of power. In Egypt designation to the warrior

class was esteemed a privilege—open only to men who owned enough tax-free land to ensure the adequate support of their families. In warlike Assyria similar provisions existed. The practice in the other great Mesopotamian empires varied, involving in some instances the levying of conscripts from subject peoples, introducing in other cases the employment of professional soldiery as the nucleus of the imperial forces. The armies developed under the application of both of these principles invariably collapsed before the impact of more homogeneous forces, as Xenophon and Alexander demonstrated. One notable example of the citizen militia of ancient times is presented by the Hebrews, as recorded in the Book of Numbers. In their invasion of Canaan they called up all able-bodied males 20 years old and upward, to the number of 603,550, a total questioned by the historians.

Like Egypt, the city-states of ancient Greece esteemed military service a high privilege, accorded to citizens alone. Only 7,200 of Athens' male population of 36,000 were excused from such service in the Periclean Age. The victories against Persia were won by true citizen levies of a free democracy, a nation in arms. It must be remembered, moreover, that the citizens made up only a minor fraction of the whole population, as low as 20 per cent of the total in some instances. The highest development of such citizen militia occurred in Sparta, where the profession of arms was the accepted career of every able-bodied male. In fact, only the strong survived the extreme rigors of the training, which began in early youth. With the launching of the successive campaigns of imperialistic expansion by Athens, Sparta, and Thebes, the demoralizing processes of substitution and payment, and the hiring of foreign mercenaries set in, bringing finally the day of the professional army, led by the soldier of fortune. Demosthenes exhorted the Greeks, all too late: «Recruit your armies, man your fleets, not with the off-scourings of Hellas and Asia, but with the best of your freeborn citizens, and you may yet conquer.»

The Romans of the early republic depended wholly on compulsory service, in striking contrast with their Carthaginian rivals, whose armies consisted of professional mercenaries. The Roman soldier furnished his own equipment and received no pay. Thus, the cavalry was drawn from the ranks of the wealthy, the infantry from the middle classes, and the poorer citizens either served as light auxiliaries or escaped military duty altogether. To the poorest class, the proletaries, was assigned the duty of staying at home as «getters of children.» Marius and subsequent adventurers, however, enrolled them for service in the field. From the very outset, delinquency on the part of the conscript was punished with imprisonment and the confiscation of his property. Liability to service extended from the age of 17 to 60, the older men being restricted to garrison duty. Under the prolonged strain of the Punic Wars, slaves and noncitizens were forced into the ranks, and payment for service was instituted. The citizen-militia had been supplanted by a professional army which was to carry the Roman eagles far beyond the limits of the then known world, becoming at the same time the tool with which its leaders destroyed the republic to establish themselves as masters of the state. Under the heavy drain of constant campaigning, increasing dependence was placed on the drafts called up from subject peoples, and on mercenaries. In the hour of final crisis, Rome had no trained reserves of citizen militia to defend the country. The Roman citizen had long since ceased to be a soldier.

The Middle Ages.—The military aspect of feudalism is marked by the use of a soldiery which at once suggests the citizen-soldier and the professional, but is neither. As General Crowder comments: «The soldier-serfs did not come to arms in the service of a common cause, but in payment of a debt of fealty to which they were not a party.» The doubtful loyalty and low efficiency of such contingents caused the soldier-kings of the day to turn to the use of mercenaries recruited from the very dregs of society, men who preyed on friend and foe alike. So dreaded were those professional soldiers by all classes of citizenry that the stigma adhering to the military profession has never been removed. The Middle Ages do, however, contribute important examples of the proper and efficient use of universal compulsory service. The North Italian communes of the 13th century, closely approaching democracies in their political and social organization, were well able to defend themselves with their conscript levies until the day when internecine strife destroyed their power. For a brief period the free cities of the Low Countries—Ghent, Bruges, and Ypres—did likewise. The outstanding instance occurred in the long struggle begun by the early Swiss cantons of Uri, Schwyz, and Unterwalden in 1291 against foreign oppression, leading ultimately to recognition of the independence of the Swiss Republic in the Treaty of Westphalia. Repeatedly, when faced by Austrian and Italian armies outnumbering them by more than ten to one, the highly trained Swiss soldiers, products of universal conscription, overwhelmed their enemies. The democratic Swiss system maintained liability to service for all men above the age of 16. The physically unfit paid a tax in lieu of service; the physically fit evader suffered heavy punishment and became an outcast.

As the great national states emerged in the 17th and 18th centuries, the supply of professional soldiers had to be supplemented by some form of compulsory military service. As applied by rulers like Louis XIV and Frederick the Great, it was neither democratic in form nor selective in application. Wholesale drafts and wholesale exemptions went hand in hand until such tyranny reached its lowest depths in the unspeakable trade in cannon fodder conducted by the German princes. The Hessians, hired by England to suppress the American colonists in the Revolutionary War, were a sample of this barter in human flesh.

Sweden for a brief instant of heroic history under Charles IX and Gustavus Adolphus merged the principles of the old feudal levy with an advanced type of conscription. It was so democratic in application that it won the wholehearted support of the Swedish people. The ambitious campaigns of later monarchs, notably Charles XII, compelled the usual resort to professional soldiery, inevitably bringing the day when the army became the tool of the despot. This indeed was the normal picture of

Europe throughout more than a thousand years preceding the outbreak of the French Revolution in 1789.

Revolutionary France.—One of the first steps of the revolutionaries was the abolition of the personal obligation of military service. The mob saw the army as an instrument of oppression, a wasteful consumer of the national income, an exponent of militarism. By December of 1789, however, the massing of foreign armies on France's borders led a French orator to declare: «I lay it down as an axiom that every citizen of France must be a soldier, and every soldier a citizen.» Nevertheless the new republic relied on the volunteer system until the disasters of 1792 led to the levy in the following year of all able-bodied citizens between the ages of 18 and 25. The new army, accepted immediately as the exponent of the joint rights and obligations implicit in citizenship, developed a spirit which made it unconquerable. The principle of the law of 1793 was given permanency in the measure introduced by Jourdain in 1798, incorporating universal service into the republic's organic law. Once again the familiar cycle of imperial expansion reappeared as Napoleon's endless demands for more soldiers led, in turn, to the conscripting of every Frenchman who could carry a gun and the drafting of the citizens of conquered territories. His system lost its democratic character when exemption by purchase was introduced. The well-to-do could evade their obligation at a price which materially swelled the national income. The financial gain was more than outweighed by the bitterness aroused among the millions whose poverty prevented such escape from military service. It led logically to the situation in 1810 when more than 80 per cent of the annual quota failed to appear for registration, and Napoleon was using 16 flying columns, an army of more than 40,000, to hunt down the *Refractaires*—French deserters. Ten years earlier Napoleon had begun to organize his armies around a solid nucleus of professional soldiers. The democratic concept of conscription had disappeared in the ranks of the autocrat's model army.

Napoleon's ruin gave the European powers a breathing space for reconsideration of their basic military policies. The French Republic had demonstrated the value of a democratically conscripted citizen army when defending itself against the foreign invader. Napoleon's career had shown how that army, converted into an instrument of aggression and personal power, destroyed the democratic basis of not only the army, but the state as well. The gain in striking efficiency of the professionalized military machine was paid for in the loss of the people's liberties. The lessons in France's experience were not read alike by the European statesmen.

Prussia and the German Empire.—Prostrated by the defeat of Jena and the terms of Tilsit, Prussia adopted Scharnhorst's plan of passing all young German manhood through a system of intensive military training. Treaty restrictions held the army to a total of 42,000 men. As a result, the recruit received little beyond basic instruction before being passed into the reserve. The wholly democratic basis of such universal service, with exemptions completely barred, revived the patriotic ardor of the people and built the army which helped to destroy Napoleon. Nevertheless that army was a tool out of place, a democratic instrument in a land whose people were psychologically fit only for autocratic rule. With the advent of Bismarck, Prussia's professionalized system of conscription was ready to convert his «Blood and Iron» thesis into a formula for conquest and the creation of the German Empire. With the extension of the Prussian system to all the empire, the German Army made ready for the test which came in 1914. Its collapse under the attacks of the Allied armies, which by 1918 were being raised by conscription measures as sweeping as those of Germany itself, brought only a brief interlude before the Nazi concept of total war extended the principle of universal service to all the populace, regardless of age or sex. Today, all must contribute, if only in the form of self-denial and sacrifice on the part of the aged and the infants.

France, After Waterloo.—France, for a period of three years after Waterloo, abandoned universal service. Its resumption in 1818 was half-hearted, the law permitting the conscript to purchase substitution. A futile effort was made by the republic of 1848 to build a reserve of citizen-militia behind the regular army, which by this time was essentially a professional machine. In 1866 less than 30 per cent of the army consisted of conscripts. Following the disaster of the Franco-Prussian War, France returned to a system of personal military liability for all able-bodied male citizens. It remained in force as to its general provisions until the day of France's surrender to Germany in May 1940. However, modifications as to exemptions, substitution, and length of the term of service have been frequent. In fact, every European country except Great Britain had adopted universal service in some form or other by 1914. Variations as to the duration of the period, thoroughness of training, and the employment of exemptions and substitution by purchase were numerous.

Great Britain.—British statesmen had insisted for centuries that democracy and British tradition were inconsistent with universal service. Today the historian sees the argument as a rationalization of the fact that since the days of the Armada, Britain had placed her main dependence on her fleet, with the result that her small land establishment could be recruited from volunteers. As for British military tradition, one finds its origin in the Anglo-Saxon *fyrd* or militia, a true instance of the «nation in arms,» antedating feudalism. All able-bodied males between the ages of 16 and 60 had the privilege, as it was termed, to take the oath of arms. It was a privilege not to be evaded, and in consequence an obligation. The militiaman, like the Roman soldier of republican days, furnished his own arms and equipment. Except for rare instances, training was neither thorough nor regular. Nevertheless, the fyrd gave, on the whole, an excellent account of itself from the days of Alfred to the opening years of the 14th century. It survived the importation of feudalism by William the Conqueror. In fact, that ruler used the fyrd to curb his troublesome barons.

The arduous foreign campaigns of the 14th century called for a soldiery with more training and skill than the fyrd provided. The monarchs of that day found the nucleus for the required

force in the small band of professional soldiers which had been a feature of every royal establishment. In the expansion of those units to provide the armies which humbled France at Crécy, Poitiers and Agincourt, volunteers came largely from the militia. Repeatedly Parliament intervened to prevent the wholesale draft of the fyrd for overseas duty, and in 1352 passed a law forbidding its employment outside the realm except with Parliament's consent in each case.

Under the Tudors, the militia system was expanded until Elizabeth, facing the threat of invasion, found on the rolls a million men liable for service. The Stuarts, however, mistrusted the democratic attitude of these citizen-soldiers, and did much to destroy their efficiency by first annulling the requirement for each man to arm himself, and then failing to provide the arms. For a brief period during the Civil War the parliamentary contingents turned professional when Cromwell inducted them into his New Model Army of 1645. That step is usually cited as the origin of Britain's Regular Army, a strictly professional organization. The militia system did not completely vanish, however. It was re-established in 1660, and it long remained the principal dependence for home defense, leading in one instance to the levee en masse when, in 1803, England prepared for invasion by Napoleon. England's foreign interests and the rapid increase of her imperial domain called for a long-service soldiery. Since the militia could not fill the need, the small professional force was expanded to become the empire's major dependence for land operations. The militia remained as a training school for the Regular Army until 1908 when it was finally classified as a «special reserve.» By that time it existed principally in theory. In the meanwhile, Parliament had provided in 1859 for a new force, the Volunteers.

British opinion in 1914 was wholly opposed to universal service, in fact barely tolerant of the man in uniform, as Kipling aptly records. Even though the Regular Army was no more than a handful and the volunteer system failed from the first to bring up more than a modest fraction of the man power needed at the front, it required three years of war to bring the country to acceptance of the universal draft. As was to be expected, the pick of the British youth, first to volunteer, were by that time only names on the «Roll of Honor.» Industry, moreover, had been largely disrupted by the «joining up» of key men. The draft laws finally enacted after such frightful waste were both universal as to obligation and selective as to application.

Switzerland.—Among the other European states, national defense was generally based on the principle of the universal draft, superimposed on a basic cadre of professional soldiery. Switzerland's record is unique. The Swiss citizen soldier, having demonstrated his merits, was in great demand everywhere as a mercenary through the closing centuries of the Middle Ages. Their quality and prestige declined in the years following Switzerland's complete independence. Napoleon had little difficulty in overrunning the country and in compelling it to furnish contingents for his imperial armies. The Constitution of 1848, as amended in 1874, re-established the principle of universal liability and substituted federal for cantonal responsibility in the training of the levies. Though never subjected to the test of arms in modern battle, the quality of the Swiss troops has evoked the highest praise from foreign observers for more than half a century.

Conscription Since 1919.—The years immediately following 1919 witnessed a continuation of the conscript system in Europe. Exceptions to that rule were the Central Powers, limited by treaties to the maintenance of armies so small that a professional force became the logical solution. In each case the men selected represented the pick of the nation's youth. (See MILITARY EDUCATION.) Another exception was Great Britain, returning to her prewar volunteer system of professional soldiery.

Germany.—With Hitler's seizure of power in Germany, the Reich reinstituted compulsory military service, this time in a form comparable with that previously adopted by Soviet Russia and Italy. Under the National Defense Law of 21 May 1935, as amended 13 July 1938, every male German is obligated to perform military service from the completion of his 18th year to 31 March of his 45th year. Active duty in peacetime begins with a tour of service in the labor corps, followed by two years in the Reichswehr. The conscript's training is provided chiefly by a cadre of professional soldiers. In time of national emergency the upper age limit of liability is extended at the discretion of the Minister of War; moreover, all women as well as men are obligated to render service over and above strictly military duty. The net result is total mobilization of the adult population.

Russia.—Soviet Russia's Compulsory Service Law of 15 Aug. 1930 establishes liability for all citizens, regardless of sex. Women are accepted in peacetime and may be drafted in time of war. The period of liability extends from the age of 19 to 40.

Italy.—Italy makes even greater demands on its people. Conscription, in the form of pre-military training, begins for every child at the age of six. When the youth of 21 begins his military service he is already a trained soldier. After a period with the colors, normally 18 months, he remains liable to the age of 55. A small cadre of professional troops is maintained.

France.—In the postwar period France moved by degrees to a system which combined a high percentage of professional troops (nearly a third of the total armed forces) and modified conscription, with liberal exemptions. The law of 28 March 1928 reduced the conscript's active service to one year, performed at the age of 21. In 1935 the period was increased to 18 months. Under the pressure of German rearmament, Parliament provided a two-year training period for the 1936–39 contingents. Liability to military service, including active duty, covered 28 years. The French collapse under the impact of Germany's blitzkrieg in May 1940 was due in part to the wholesale abuse of the exemption privilege. Intended to avoid undue wastage of key men in industry and professions, it actually worked to place the peasant and laborer in the trenches, while the well-to-do and the middle classes escaped the draft. Such election to the role of cannon fodder was a powerful factor in the inability or refusal of the French soldier to stand up against the German attacks.

Great Britain.—Continuing her precedent of the World War, 1914–18, Great Britain's approach to the problem of conscription in 1939

was little more than a military gesture. The Conscription Act passed in May 1939 provided a six-months' training period for all British youths in their twenty-first year. At the conclusion of training the conscript was given the option of joining the Territorials for three and one-half years or being placed in the Regular Army Reserve. Conscientious objectors were required to give six months' service on civil projects, in lieu of military training. Reinstatement of drafted employes in their former jobs, upon return from service; a moratorium on their payments of interest, premiums, and installments during the training period; and an increase of 50 per cent in the pay of the common soldier were among the benefits extended by the act. Registration on 3 June 1939 was followed by induction of the first contingent, about 35,000 men, 15 July. The plan called for the training of some 200,000 men in the first year; 800,000 in three years. Conscription of all males between the ages of 18 and 41 was provided for in the act of 3 Sept. 1939, the date of Great Britain's declaration of war against Germany. Meanwhile the call to service of the contingents registered under the earlier act proceeded tardily, disregarding the fact that the rate of volunteering during the months of the «white war,» prior to September 1939, was insufficient to bring the pitifully small Regular and Territorial armies up to authorized strength. National registration, roughly comparable to an American census, was accomplished, 29 Sept. 1939. It established the basis for not only the registrants' call to military service, but for wartime rationing, identification of individuals, and segregation of those who might interfere with the prosecution of the war. The most far-reaching measure of Britain's military history, entitled the Emergency Powers Defense Bill, was passed 22 May 1940. It provides for the draft of all British resources, material as well as human, during the period of the emergency. Legally at least it parallels the totalitarian measures adopted earlier by the dictator states.

Japan.—The universal compulsory military service law with which Japan emerged as a modern state is the logical continuance of a militaristic tradition antedating the nation's historical record. Liability to service covers the 24 years between the ages of 17 and 40, inclusive, for all males. Actual service begins in the twentieth year. Registrants are divided into five classes, according to physical fitness. Normally only the two upper classes, the «absolutely fit» and the «fit» are called to the colors. However the unending strain of the war in China compelled Japan not only to reduce her minimum physical standards, but to induct into her field units men classed as «fit for national service but not for active service.» In peacetime the conscript receives two years of training with the colors and thereafter, as a reservist, is called up for short periodic tours of duty. Service in war is for the period of the emergency. A sound system of selection guards industry against disruption by the execution of the draft. The extension of that principle under the National Mobilization Law of 1938 has produced totalitarian conscription, similar in all major respects to the Nazi model.

American Experience.—Each of the original thirteen colonies had its organized militia, a counterpart of similar British forces. Massachusetts in 1774 inducted one-fourth of her total militia levy into her organization of «minute men.» Their status was neither that of conscripts nor volunteers, but something of both. The same uncertainty occurred in the raising of similar levies in the other colonies. However, «volunteering» usually was placed on a basis suggesting compulsion whenever a colony found itself invaded. In 1777 both Massachusetts and Virginia resorted to outright conscription, after the bounties offered had failed to supply the necessary quotas. The following year Congress recommended that the states draft men for nine months, with the promise of earlier discharge if volunteers should come forward in sufficient numbers. Washington repeatedly, and without avail, recommended to Congress provisions for a general draft. The failures, heavy losses and undue prolongation of the War for Independence are chiefly chargeable to dependence on the volunteer system of recruitment.

A law embodying Washington's recommendations was passed by Congress 8 March 1792, establishing a uniform militia, to include all able-bodied men between the ages of 18 and 45. The militiaman was required to provide his own equipment and uniform, but no penalty was attached to his failure in compliance. The net result was a paper scheme establishing 15 armies, one for each state. Its utter ineffectiveness was fully demonstrated after the outbreak of the War of 1812. Notwithstanding constitutional provisions empowering Congress to «organize and arm the militia,» several states refused to furnish the requisitions of troops required to man the military posts which had been stripped for the invasion of Canada. In 1813 the Senate defeated a militia organization bill passed by the house. Political maneuvers defeated a second and more far-reaching bill in 1814. The single real, though illegal, instance of conscription during the war was furnished by Andrew Jackson in the defense of New Orleans, where he compelled many citizens to join the ranks.

America's faith in the volunteer system, bolstered by success in the Mexican War, finally vanished in 1863. Previously, on 4 Aug. 1862, President Lincoln had called on the states to provide 300,000 militia for nine months' service, declaring that failure to provide the men would result in imposition of the draft. Unable to find the volunteers, the states were likewise incapable of executing a draft. On 3 March 1863, the Enrolment Act became law. To establish its constitutionality the Republicans fell back on the constitutional power of the federal government to raise armies, in which they were upheld by the Supreme Court. The law declared the liability to military service of all able-bodied males between the ages of 20 and 45, allowing for certain exemptions. Colonel James B. Frye was detailed as provost marshal general. All his assistants, to include the personnel of the boards set up in the congressional districts, were federal officials—usually army officers. Registration was a first function of such boards, followed by the examination of pleas for exemption. The entire procedure was federal, to include the compulsory registration of every man, which often occurred at the point of the bayonet. Four months of work left the registration still incomplete. Meanwhile 98 registrars had been killed or wounded. When the time came to in-

duct the registrants into the service, the states were given one more opportunity to furnish their quotas on a voluntary basis. As a result, wealthy men purchased exemption by hiring substitutes, while the poor were forced into the ranks. Draft riots broke out in many parts of the country. In New York City, a reign of terror prevailed for three days. (See DRAFT RIOTS.) Before the end of the war, the Draft Act had brought into the ranks approximately 1,300,000 men. Of that number only 46,347 were actually drafted. Coercion or the bounty had brought the rest into the army as volunteers.

When America entered the World War in 1917, it had still to experience the operation of universal military service laws. Capitalizing on the salutary lessons learned from the failure of the Civil War draft and Great Britain's bungling after 1914, the War Department prepared a bill which was wholly democratic in its application and administration. As enacted 18 May 1917, it placed the enrolment and registration machinery in the hands of local civilian boards, supervised by the states, with the whole process integrated by the federal government. Substitution and discharge by purchase were barred. By the evening of 5 June 1917, the day set for registration, the enrolment of 9,925,750 males, between the ages of 21 and 31, was virtually complete. Selection from that pool of the men actually needed for military service, and the exemption of those required for essential industries and agriculture were likewise left to the local boards. The actual summons to military service was determined by lot in the office of the Secretary of War 5 July 1917. In September the first draft of 687,000 men went to the training camps. Supplementary legislation enacted in May 1918 increased the enrolment by 912,564, through the addition of men who had reached the age of 21 after 5 June 1917. A «work-or-fight» regulation was promulgated to force idlers and individuals in nonproductive occupations to choose between employment in some essential enterprise or induction into the military service. A second and final Selective Service Act enacted 31 Aug. 1918, embracing all men between the ages of 18 and 45, brought total enrolment to 24,234,021, of which 2,810,296 were mobilized by 11 Nov. 1918. The volunteering activities of the armed services were terminated by the act, leaving the draft as the sole source of recruitment. The constitutionality of the selective service legislation has been challenged repeatedly, from 1917 down to the present, but invariably it has been upheld by the courts. The most recent challenge was made by Grover Cleveland Bergdoll, draft evader, challenging the jurisdiction of army courts-martial at the time of his conviction. The ruling of Federal Judge John C. Knox served to establish such jurisdiction until 3 March 1921, the date that a state of peace with Germany was declared.

The dictators' challenge to democratic institutions the world over led in 1940 to the furthest extension of compulsory service in American history—peacetime conscription. The Selective Service Training Act signed by the President, 16 Sept. 1940, embodies every major determination arrived at by the Joint Army and Navy Selective Service Committee after years of study. Such study has, in fact, been continuous since the passage of the National Defense Act of 1920, charging the War Department with the preparation of plans, in conjunction with the navy, for the mobilization of the nation's manhood. The striking success of the conscription program in the World War of 1914–18 had laid the major lines which must be followed. As introduced in Congress, and enacted into law, the War Department bill places its emphasis on decentralization and intimate local administration. Central direction and coordination only is left in the hands of the National Selective Service Headquarters in Washington, D.C., headed by Dr. Clarence A. Dykstra, president of the University of Wisconsin, appointed by President Roosevelt as director of Selective Service. Broadly speaking the law aims to mobilize the nation's man power with the least possible disturbance of the national economy and the individual's normal life. The Presidential proclamation of 16 September charged the governors of the various states and the commissioners of the District of Columbia with the responsibility of providing suitable and necessary facilities for registration in local communities. Provisions for the corresponding procedure in the territorial possessions of the United States were left to future proclamations. Registration Day, 16 Oct. 1940, brought some 16,500,000 men, between the ages of 21 and 35 inclusive to their respective election precincts. Two classes were exempted from the process: individuals already in the land and naval forces of the United States, and foreign diplomatic and consular personnel resident in this country who had not declared their intention to become American citizens. All other alien residents, however, were required to register. Special provision was made for delayed registration of men prevented by illness or residence abroad from registering on the day appointed. Questionnaires were sent the registrants shortly after the time of their enrolment, to be filled out and submitted promptly to the local selection boards. These boards, approximately 6,000 in number, were wholly civilian in their makeup, consisting of local personnel best qualified to judge the availability of the registrant for military service. Their principal function is the classification of the registrants into four groups, as follows: (1) available for immediate service; (2) deferred because of the importance of their service to the nation; (3) deferred because of dependents; (4) deferred by law or for physical disability, or because induction was deemed undesirable to the government for other reasons. A lottery operated in the national headquarters established the call numbers for all Class 1 registrants.

Both the registrant and the government were given the right of appeal from the board's decisions as to classification. By using the services of eminent medical specialists in doubtful physical cases and by confining the basis of appeal to documentary evidence, excluding oral or written argument by counsel, the expeditious handling of appeals was assured. Conscientious objectors' claims to exemption were submitted to the Department of Justice for investigation, with the proviso that the local board might register them as liable for noncombatant military duty. Upon the receipt of the Class 1 lists, state headquarters made consolidated returns to the national headquarters, receiving in turn the state quotas for redistribution to the local boards. Deferment of induction for certain Class 1 reg-

istrants was provided in cases where Congress deemed that undue hardship might be inflicted. In particular, such deferments prevent unreasonable interference with the completion of registrants' college education. Concern was also shown for the selectee's rights, as indicated in the following provisions of the law:

(1) Prohibition against his employment in the armed services outside the Western Hemisphere.

(2) The privilege of taking his year's service as a volunteer instead of as a conscript.

(3) Trial by civil court of the selectee who dodges service or gets into other legal difficulties prior to induction. Courts-martial are given jurisdiction over selectees only after actual induction.

(4) Thorough physical examinations at the beginning and end of the year's service to establish any possible claim for physical deterioration as a result of military service.

(5) The grant of a certificate at the completion of the year's service, with compulsion upon the employer to reinstate the man in his former job within 40 days after completion of such service and without loss of seniority «unless the employer's circumstances have so changed as to make it impossible or unreasonable to do so.» The employer moreover may not fill the position vacated by the selectee with a member of the Communist party or the German-American Bund.

(6) The barring of discrimination on the grounds of race or color.

(7) Authorization of voting by absentee ballot; if the selectee's place of voting is within one day's journey of the place of military service, he may vote in person.

(8) Pay, after 1 October for all privates in the land and naval forces at $21 per month for the first four months, and at $30 per month thereafter. Moreover, the trainee is eligible for all rights and privileges provided by law for enlisted personnel of the Regular Army.

(9) Limitation of military service to one year unless Congress later determines that the national security requires its extension beyond that period.

(10) Protection against repossession by sellers of articles purchased by selectees under the installment plan prior to induction on the ground of nonpayment during the year of service.

The first contingent of 18,700 was called to the colors on 25 Nov. 1940, the advance guard of a total of 789,000 to be called up by the end of June 1941. Net quotas for the states to June 1941, after deduction of the totals already in the army and navy by voluntary enlistment, were as follows: Alabama, 13,711; Arizona, 3,098; Arkansas, 8,946; California, 38,017; Colorado, 3,837; Connecticut, 8,421; Delaware, 1,329; District of Columbia, 3,982; Florida, 10,370; Georgia, 12,792; Idaho, 1,954; Illinois, 62,223; Indiana, 21,087; Iowa, 11,738; Kansas, 8,388; Kentucky, 9,154; Louisiana, 15,084; Maine, 3,081; Maryland, 12,564; Massachusetts, 20,556; Michigan, 47,282; Minnesota, 18,652; Mississippi, 12,759; Missouri, 23,619; Montana, 2,563; Nebraska, 6,456; Nevada, 624; New Hampshire, 1,579; New Jersey, 32,170; New Mexico, 2,962; New York, 114,796; North Carolina, 15,613; North Dakota, 3,401; Ohio, 52,497; Oklahoma, 9,365; Oregon, 2,806; Pennsylvania, 61,522; Rhode Island, 3,118; South Carolina, 5,957; South Dakota, 3,525; Tennessee, 14,229; Texas, 33,213; Utah, 2,153; Vermont, 1,206; Virginia, 9,747; Washington, 5,821; West Virginia, 8,454; Wisconsin, 21,632; Wyoming, 1,047; United States: 789,000.

The training program, dovetailed with those of the National Guard units called into the federal service for one year and the newly organized units of the Regular Army, was scheduled to increase the Army of the United States to more than 1,200,000 by 1 April 1941. Its continuation is provided by the annual registration of men not previously registered, whose ages fall within the limits prescribed by the Selective Service Act. The measure provides for its own termination 15 May 1945, unless amended or repealed at future sessions of Congress.

Widespread opposition to the bill marked its passage through Congress. Analysis of the hearings and the debate in both houses shows certain groups to have been responsible for most of the hostility manifested, among them: important elements of the clergy, all the left-wing radicals, organized pacifists, and racial groups sympathetic to the Nazi-Fascist program of expansion. The principal charge leveled against the measure was its alleged destruction of democratic principles and its encouragement to dictatorship. The needless financial cost of conscription and the absence of any danger to America from abroad were also alleged. However, the separate Senate and House bills passed by majorities of 58 to 31 and 263 to 149, respectively. Major differences left to conference included a Senate provision for the «drafting of industry,» and the age limits set by the two houses. As finally passed, the bill provides that manufacturers are required to accept and execute on «fair and just terms» orders for materials and supplies required for the national defense when called upon to do so by the President. Refusal to comply renders the manufacturer liable to a maximum prison sentence of three years and a maximum fine of $50,000. In addition, the President is authorized to take over and operate a plant at a «fair and just» rental for similar purposes. The cost of one year's operation of the bill is estimated at $1,600,000,000, representing the absorption of approximately one-tenth of the nation's industrial output. The final vote on the compromise measure submitted by the joint conference gave a majority of 47 to 25 in the Senate, 232 to 124 in the House. See also MILITIA; NATIONAL GUARD.

CONSCRIPT DE 1813, Histoire d'un (HISTORY OF A CONSCRIPT OF 1813), a famous story, by Erckmann-Chatrian, published 1868–70. The narrative turns mainly on the contrast between the perpetual mourning that is going on in families and the perpetual Te Deums for disastrous victories. This is the dominant note; and in the mouth of the humble conscript, this thesis, interpreted by scenes of daily carnage, is more eloquent and persuasive than if it borrowed arguments from history or philosophy. The style is simple, familiar; but never trivial or commonplace, and is always in harmony with the speaker. As the work was hostile to the Napoleonic legend, numerous ob-

stacles were put in the way of its circulation at the time of publication. But notwithstanding, it was scattered in profusion throughout France by means of cheap illustrated editions.

CONSECRATION, an act by which material things and persons are dedicated to sacred uses and sacred ministries. Celebrations of rites of consecration are traced back to the earliest historic periods of Assyrian, Chaldaic, Egyptian and Hebraic civilizations. The word Consecration is also used in the Roman Catholic ritual and liturgy to signify the act of Transubstantiation (q.v.) by which the bread and wine are in the Mass changed into the body and blood of Christ. In the Roman *Pontificale* or ritual for episcopal functions there is a form for consecration of a bishop, consecration of a church, consecration of the sacred vessels used in the liturgy of the Church. In the consecration of a bishop—ordinarily performed by the metropolitan and two other bishops—the consecrating bishops impose hands on the bishop-elect and the metropolitan delivers to him the pastoral staff and the ring, emblems of his office, and anoints him with chrism, the sacramental mixture of olive oil and balsam, pronouncing the formula of words by which is expressed the commission of authority to rule the Church committed to his charge. The consecration of a church is a very elaborate ceremony, requiring several hours to complete it: there is chanting of the office of Matins and Lauds by the clergy; there are processions of clergy, headed by the consecrating bishop and other bishops who may be present, around the walls outside and thrice around the interior, with continuous chanting of psalms; there is anointing of the doors, of the walls, of the high altar; and a number of other rites. The consecration of the vessels destined for the service of the altar is also an episcopal function: it is a rite that has descended from high Christian antiquity; in this rite also chrism is employed.

CONSENT (OF. *consente,* Lat. *consentire,* «to agree»), *in law,* a free and deliberate act of a rational being. Any voluntary act by which the agent takes away his own power of giving a deliberate consent, such as partial intoxication, will not invalidate the consent; but it is invalidated by any undue means—intimidation, improper influence or imposition—used to obtain it. The law does not, in general, take cognizance of the wisdom or folly of men in entering into contracts before it enforces them; but where clear proof can be brought that a person has been wilfully misled or entrapped into a contract, it will refuse to enforce it. In pathology consent signifies an agreement or sympathy in virtue of which one affected part of the system affects another part or parts.

CONSEQUENT STREAM. On a newly emerged portion of the sea bottom, forming a coastal plain sloping toward the ocean, the run-off from rainfall gathers into little rivulets that flow down the slope to the sea. These channels enlarge till finally the water courses constitute true rivers. Streams like this, whose course is determined as a consequence of the initial slope of the land, are called consequent streams. See also SUBSEQUENT STREAM.

CONSEQUENTIAL DAMAGES OR LOSSES, *in law,* are losses incurred in consequence of an act, but not flowing directly from it. The liability for consequential damages resulting even from an unlawful act is more limited than that for direct damages, as it is evident that the power of the law in tracing and enforcing such damages must be limited; but in some cases they can be enforced.

CONSERVATION OF ENERGY. See ENERGETICS.

CONSERVATION OF MATTER. See MATTER.

CONSERVATION OF NATURAL RESOURCES. Americans, who until the close of the 19th century still exulted in the strength of their limitless resources, in the first decade of the 20th century began to regard the protection of the rights of the people in the public domain as more important than the immediate exploitation of its wealth, and began to favor public control and legislative limitations on private enterprise as essential to industrial liberty and the general welfare. Fearing the exhaustion of their natural resources, they expressed their fear in a well-developed movement for conservation. They urged more careful attention to the soil with a view to restoration of fertility by scientific farming. They favored government projects for extension of irrigation begun by private enterprise. They sought to find plants and methods which would bring crops to semiarid areas and unirrigated deserts. They sought through national and State governments and great corporations to establish forest reserves to prevent exhaustion of timber and to prevent alternate floods and droughts, and encouraged scientific study of forest problems. They began an agitation to prevent waste of supplies of coal and iron, and to save coal supply, by urging the importance of the preservation and development of latent water power to produce electricity. They were awakening to the fact that power sites should be leased, not sold or given away, and that privileges of using this natural source of wealth should be granted on terms conserving the rights of the public to adequate service at a reasonable charge. They lessened the demands on forest and iron ore by use of cement as a substitute for wood and iron. Finding that a large amount of the resources upon which the future must depend were held by a comparatively few individuals or corporations, they began to demand that the unappropriated resources should be administered primarily for the benefit of the public, and that those already in private hands should be subject to government control. They began to urge selection of trained experts to study the economic utilization of resources, and co-operation to regulate the life of the community for the good of all.

With changes of conditions which brought a realization of dangers from waste, the need of a national policy of conservation arose. A rise of prices of raw materials in connection with every resource is probably the strongest economic force leading to more scientific utilization, and this is the strongest guarantee of conservation, but legislation is also needed.

The Roosevelt administration first saw the importance of a more active national control of natural resources for the benefit of the public. In February 1907, calling attention to the waste of mineral resources, the President

recommended legislation for separation of the title to the surface of the land from the title to the underlying mineral fuels, in order that the latter at least might be withheld from monopolizing or speculative private interests and kept for the public benefit. He considered that "the conservation of our natural resources and their proper use constitute the fundamental problem which underlies almost every other problem of our national life." Early in 1907 he took the first practical step toward the solution of the problem by the appointment of the Inland Waterways Commission to investigate and recommend a full and comprehensive plan for the development and utility of the water resources of the country. In May 1908 he took the second step in calling at the White House a conference of governors to which facts regarding natural resources were presented by experts and at which plans for conservation were considered. This conference began a definite movement for conservation. Following its first meeting the President took an additional step by the appointment of a National Conservation Commission composed of about 50 members under the chairmanship of Gifford Pinchot who was head of the forestry division. This commission made the first national inventory of natural resources, published in 1909. It directed attention to the waste in extraction and treatment of mineral products, the decrease of soil fertility, the extinction of wild game and fur-bearing animals, the decrease of forests by timber industries and by fires, the waste of water in public and private irrigation projects and the great losses by failure to utilize the power of water flowing over government dams.

Disclosures of recent government investigations thus begun are appalling. Experts report that many natural resources are rapidly nearing exhaustion; that at the present rate of consumption and with present wasteful methods the timber can last only 30 or 40 years, that the supplies of available coal can be expected to last only 150 years, and the supply of petroleum only 50 years, that the supply of high grade iron can last only 100 years and the known copper deposits only 50 to 100 years.

Advocates of the new policy proposed not only to conserve by more economic methods of extraction but also by substitutes to reduce the consumption. The storage and properly directed release of vast water power which has remained uncontrolled and unused can be made to save other resources from damage and at the same time to conserve enormous supplies of coal. By complete utilization of this neglected resource, floods may be reduced, better means for irrigation provided, waterways improved for navigation, and larger power secured for industrial purposes.

President Roosevelt withdrew large areas of western public land from sale and settlement for the purpose of investigating their resources, and recommended legislation for protection of the interests of the general public in their forests, minerals and water powers. Important steps toward a national policy were taken by the creation of national forests (under acts of 1891 and 1907) and the Forest Service. The latter is a bureau of the Department of Agriculture which successfully protects and administers the public interests in the national forests, which contain one-fifth of all the standing timber in the United States, protect the headwaters of every western river and aid in supporting half the sheep in the western ranges. It also co-operates with State bureaus. It protects the forests from fire and depredations, improves the conditions for timber growth, protects the water supply and utilizes the forage crop. Besides the practice of scientific forestry it conducts investigations and collects much useful information for dissemination. The new policy defeated the attempts to cede the national forests and the entire public domain to the Western States which cannot so well administer them in the interests of the whole people.

In the Far West a decided opposition arose against the new forest policy, but by 1911 the policy of Congress not to release any of the safeguards against the forestalling of land by corporations and large individual owners and to continue the forest policy and to reserve public mineral rights became clear.

In 1911–12 Congress began appropriations for the purchase of forest reserves in the Appalachian and White mountains.

In 1909, the first steps were taken to prevent plans of great capitalists to obtain control of valuable natural resources in Alaska. Ex-President Roosevelt led in the support of a plan of government ownership with leases to corporations.

The conservation policy was also manifested in the agitation to reserve water-power sites, to secure new laws for the disposal of coal lands and to modify the Homestead Act. By act of 1910, the President can reserve public lands for water-power sites or irrigation. The Secretary of the Interior recommended that the Federal government be authorized to lease such power sites at a moderate rate for a period of not to exceed 30 years. It has been urged that the development of power in navigable and source streams should be co-ordinated to reduce drain on other resources, to aid in the control of streams for navigation, to prevent soil wash and to purify water supply. For the proper conservation of water power the most important thing is to prevent private monopolies from getting the sites and to preserve the use of them for the benefit of the whole people. The importance of this is indicated by the fact that 65 per cent of all the developed water power of the United States was controlled by 10 groups of power interests, several of which were closely related by interlocking directorates. The new policy of national conservation defeated the latest selfish attempt of organized power interests to obtain in perpetuity and for nothing the unregulated control of water powers of navigable streams in the national forests and on the public domain.

Recently the Federal government has begun active participation in the reclamation of arid lands by irrigation projects which were first begun by private corporations as early as 1880. The national irrigation policy emerged from disputes of western farmers with the large private water companies which by 1900 had secured and developed the best irrigation sites, and also from the necessity of protecting rivers and lakes from which irrigating waters were drawn. The Federal government has encouraged irrigation by the desert land laws of 1877 and 1891, by the later Carey act of 1895 (modified in 1901 and 1908), and by the more

important Newlands reclamation act of 1902, by which the government began to reserve from settlement many areas of water supply and could hold the mountain streams necessary to fill reservoirs and use the water drained from the dams. Congress advanced $20,000,000 for the construction of irrigation dams to be satisfied from the proceeds of the sales of the improved land.

Congress has gone far toward committing the government to the policy of control by authorizing the President to withdraw public lands from private use whenever important for conservation of forest or grazing lands, water power, irrigation possibilities or scenic beauty, but has not yet determined the terms on which mining and development rights will be conceded. Little effort has been made to protect mineral resources from waste or improper exploitation. In 1900, Congress enacted a law authorizing the President to withdraw temporarily from settlement and sale and to reserve for public purposes any lands in the United States and Alaska or to reserve as government property the coal and other minerals beneath the surface. The National Conservation Commission advocated the disposal of coal lands only under leases safeguarding the interests of both the mining investor and the public. Steps were taken to withhold from private ownership the coal deposits in Alaska, and the government undertook the construction of a railway leading to the Matauska coal field. This is the beginning of a new system in line with the example of many European countries.

Another illustration of the new policy of conservation is found in the guarding of the north Pacific seal fisheries by an international agreement of 1896 between the United States, Great Britain and Russia, and by a later treaty of 1911 in which Japan joined.

To make resources safe from waste and unregulated monopoly, the advocates of conservation still urge legislation for the development of water power of the national forests and other public lands on terms fair both to the people and to the power interests, for improvement of public grazing lands by regulated use, for preventing by adequate penalties the needless pollution of streams, and for the utilization of the resources of Alaska for the benefit of the people.

E. and Whitaker, J. R., eds. 'Our Natural Resources and Their Conservation' (New York 1936).

JAMES M. CALLAHAN,
Professor, West Virginia University.

CONSERVATIVE, as applied to one of the two great parties in English politics, was first used by J. W. Croker in an article in the *Quarterly Review* for January 1830, and was by Macaulay, in the *Edinburgh Review* for 1832, referred to as a «new cant word.» Conservative accordingly began to supersede Tory about the time of the Reform Bill controversies. The plural form of the word, or its equivalent in other tongues, has been assumed as a distinctive name by certain political parties in many nations. These parties are sometimes actually, and always avowedly, opposed to changes from old and established forms and practices. In United States history these names have never been in general use, but in Van Buren's administration the name of Conservatives was applied to those Democrats that at the special session of Congress of September 1837 opposed the establishment of the sub-treasury system. In the Congress that met in December 1839 they had practically disappeared. The name was also assumed by Southern whites during the reconstruction period following the Civil War, to show their adherence to the old State governments, the abolition of which by Congress they opposed. In Virginia the name was in use until 1872. The name was also used in the North during this period. The Democrats applied it to themselves to draw moderate Republican votes. In the United States (1830–40) the name of Conservatives was adopted by seceding Democrats, 4 in the Senate and 14 in the House, who voted with the Whigs against the sub-treasury, though voting with their party on other questions. They called themselves Conservatives, as wishing to conserve the prosperity of the State banks, which they held the sub-treasury to be a disguised attempt to ruin. They held the balance of power in the House 1837–38, and voted down in two successive sessions Silas Wright's sub-treasury bill, which had been passed by the Senate. The elections of 1838, however, returned only four of them to the House, and these ceased their active opposition — partly because the government had only escaped bankruptcy in 1838, on account of uncollectible claims against banks and individuals, by issuing fresh treasury notes in place of those canceled. The Whigs held the power and passed the Wright bill in 1840. In the Civil War the Northern Democrats, and especially the border State Democrats, often called themselves Conservatives, as wishing to preserve the old balance of State and national powers; and the name was much ridiculed by the other side. During the Reconstruction period, the Southern whites to a considerable extent took the name of Conservatives as wishing to preserve their old State governments, which they held to have the same existence and sovereignty as before the war, according to the declarations of the Northern leaders and Congress themselves, in stating the purposes of the war. The name, more particularly in Virginia, lasted down to 1872. See TORY; WHIG.

CONSHOHOCKEN, Pa., borough of Montgomery County; alt. 64 feet; on the east bank of the Schuylkill River; 14m. NW. of Philadelphia; on the Pennsylvania and the Reading railroads. It is in a good farming country, in which are valuable clay pits. The borough makes iron and steel, textiles, tires, tanks, pumps, boilers, glass bottles, electric construction materials. Conshohocken was founded after the building (1825) of the Schuylkill Canal and became a borough in 1850. Its Indian name means 'pleasant valley.' Pop. (1940) 10,776.

CONSIDÉRANT, kôn-sē-dā-räṅ, **Victor Prosper,** French Socialist: b. Salins, 12 Oct

1808; d. 27 Dec. 1893. After being educated at the Polytechnic School of Paris, he entered the army, which, however, he soon left to promulgate the doctrines of the Socialist Fourier. On the death of his master (1837), Considérant became the head of his school, and undertook the management of the *Phalange*, a review devoted to the spread of their opinions. Having gained the support of a young Englishman, Mr. Young, who advanced the money, Considérant established, on a large estate in the department Eure et Loire, a Socialist colony or *phalanstère*, but the experiment failed, and with it the *Phalange* fell to the ground. Thereafter he continued to promote his views in the *Democratie Pacifique*. Among his numerous writings, the chief is the 'Destinée sociale,' dedicated to Louis Philippe, which contained little more than a review of the principles of Fourier. In 1849 Considérant as a member of the Constituent Assembly was accused of high treason and compelled to flee from France. Near San Antonio, Tex., he founded a Socialist community, *La Réunion*, which flourished for a time, but afterward came to nothing and he returned to France in 1869. Of his works, the one which has the greatest claim to originality is his 'Socialisme devant le vieux monde' (1849). In religion Considérant was a conservative; and was also opposed to the Revolution.

CONSIDERATION, a legal term covering the principle governing contracts and signifying something in the way of price or compensation which may be of value to the contractor or of detriment to the contractee. In law no contract is valid if it does not expressly stipulate the amount or consideration for which any lease, sale or transfer is made. As there are various kinds of contracts recognized in law, so are there different sorts of considerations. The simplest case is that where one party surrenders some property right to another for a consideration. In dual contracts the promises are mutual — each promising a consideration to the other. But whatever the nature of the contracts — and they grow in complexity from day to day — no legal action can be taken upon them unless the consideration is clearly specified therein. But considerations need not always involve direct benefits to the contracting parties. Promises made *after* services rendered cannot become the basis of legal action, because such services are not rendered *in view* of a consideration. Thus, promising a reward after being saved from drowning, for instance, does not make one liable. Nor are promises binding when they involve the performance of what is one's legal duty, anyhow. No promise is legal which involves the performance of an illegal act. The adequacy or inadequacy of a consideration, however great or small, never matters in law. Thus, one may legally transfer property rights worth thousands of dollars in consideration of one cent.

The history of the law of contracts, could it be entered into here, would show the origin of the requirement of consideration. It clearly grew out of the original custom of requiring proof of damage or detriment suffered by the plaintiff seeking pecuniary consideration. Consideration as applied to a court, in legal phraseology, means the judgment of the court, "it is considered by the court" being equivalent to "it is adjudged by the court." See CONTRACT.

CONSIGNMENT, in law, the act of sending goods, as to an agent, for sale; also, the goods so sent. The one who sends the goods is known as the consignor, and the one to whom they are sent is known as the consignee. Usually when a consignment is sent by common carrier a bill of lading is given which serves as a receipt and contract of shipment.

CONSISTORY, in ecclesiastical usage, means a court or council of ministers and Church officials or dignitaries, for transaction of business relating to the Church. In the Roman Catholic Church the Consistory by eminence is the whole college of the cardinals, which is, so to speak, the Pope's senate, assembled at stated or occasional times to deliberate questions of Church administration. It is usually presided over by the Pope in person, but often by his delegate; the stated meetings are twice a month; the sessions are secret usually and the meeting is merely formal, but often they are public when the cause of the meeting is the conferring of the hat on newly created cardinals; or semi-public, Church dignitaries of rank inferior to the cardinalate being admitted, the purpose of the meeting being to discuss a canonization. In the Church of England every bishop of a diocese has a consistorial court for determination of ecclesiastical causes arising within his jurisdiction.

CONSOLACION DEL SUR, kōn-sō-lä-thē-ôn' dĕl soor, Cuba, the name of a district and a city in the eastern central part in Pinar del Rio province. It has railroad communication with Havana. Pop. of the district about 17,000; of the city 3,062.

CONSOLATO DEL MARE, kŏn-sō-lä'tō dĕl mä'rĕ, a compilation of sea laws. See COMMERCIAL LAW.

CONSOLIDATION OF SCHOOLS, the term used when two or more rural school districts are made into one district, one school in one building replacing two or more small schools in several buildings. In most districts this includes the transportation of pupils to the school at the public expense, either in special vehicles provided by the school, or in private vehicles, the expense being paid by the school. The primary motive is to secure better educational advantages for the pupils of the rural districts. The district schools have been pitifully inadequate because their number made necessary small salaries, and therefore poor teachers and poor equipment. The plan of the consolidated school is, in brief, as follows: two, three, four or five existing school districts, each maintaining small, inefficient rural schools, vote to unite their schools, or are consolidated by some central authority. A three- or four-room schoolhouse, built on modern lines, well ventilated and heated is erected at some central location. Arrangements are made for the transportation of all of those students living at a distance. The school is organized under a principal, and often several consolidated schools unite in employing a supervising principal and teachers in special branches. The stimulus has been great enough in many cases to instigate the formation of a high school, grade school

and a specialized teaching staff. This plan of union is not possible in mountainous or sparsely populated districts. The advantages are numerous, although at first the Middle Western States which are now the strongest supporters of the plan objected strenuously. The first improvement is to be found in the better teachers and the greater interest shown on the part of the teacher and pupil. Secondly the opportunity for the country boy or girl is made equal to that of the city pupil, on account of the increased curriculum, the better organization and instruction and the other activities opened up for the country child. A third advantage is the cheaper cost. The effect on the neighborhood has been to increase interest and pride in the school and the stimulating of effort to provide better trustees, teachers and equipment. The objections, that the consolidated school is impractical, burdensome to the children, and depreciates value of the property near which the school formerly stood, have been removed slowly by experience, and the consolidated school has become a well-recognized institution both in the United States and Canada.

The movement began in New York State in 1853, when an act was passed permitting consolidation, known as the Union School Law, incorporated as Title IX of the Consolidated Act of 1864. Massachusetts followed next, and the movement spread rapidly. The North Central States have made excellent progress in consolidation; and nearly every State has some provision for union schools.

H., 'Conveyance of Children to School in Massachusetts' (in *Educational Review*, February 1894, Vol. VII, pp. 147–153); *State School Reports*. Many of these contain good articles giving progress and condition in the several States. See especially Arkansas (December 1910); Illinois (4th ed., 1914); Kansas (1908); Kentucky (1913); Indiana (1911–12, pp. 105–159); Michigan (No. 19, 1906); Mississippi (May 1913); Nebraska (1910); etc.; Betts, G. H., and Hall, O. E., 'Consolidation and Rural School Efficiency' (in 'Better Rural Schools,' Indianapolis 1914); Knorr, G. W., 'Consolidation of Rural Schools and Organization of a County System' (Washington 1910, U. S. Dept. of Agriculture, Bulletin 232); Duke, E. A., 'School Consolidation in Oklahoma' (1926); Little, H. A., 'Potential Economies in the Reorganization of Local School Attendance Units' (1934).

CONSOLS, or CONSOLIDATED ANNUITIES, a public stock once forming the greater part of the national debt of Great Britain. It was formed in 1757 by an act consolidating several separate stocks bearing interest at 3 per cent into one general stock. At the period of consolidation, the principal of the funds united amounted to $45,689,105; but, with other loans added, grew to $2,887,000,000 in 1914 in 2½ per cent consols. The amount was greatly reduced by exchange for war loans. There are also 4 per cent consols, issued in 1927, the two forming less than half the funded debt.

CONSONANCE. See CONCORD.

CONSONANT. See ALPHABET.

CONSORT, he, she or that which shares the same lot with another; a companion; a partner; an intimate associate; a wife or husband; applied in a modern sense chiefly to persons of royal degree or position, in countries where women are able to reign; as a queen consort; a prince consort; that is, the wife of a reigning monarch, or spouse of a queen-regnant. It is also applied to a ship sailing in company with another.

The queen consort, the wife of the reigning king, is, in all legal proceedings, looked upon as a single, not as a married woman. She may purchase and convey lands, grant leases and do other acts of ownership without the intervention of the king. She may also sue and be sued in her separate person, and possesses courts and officers distinct from those of the king. She pays no toll, and is free from any fine which a court could impose upon women in general; but in other respects she is on a similar footing with the other subjects of the king. In her life and person, however, she enjoys the same protection as the king, it being high treason to design the death of either. The husband of a queen-regnant is not endowed by the constitution with any distinctive rights or privileges. All his privileges and honors, therefore, must emanate from the Crown, under the form of a warrant, grant or patent, or else be conferred by act of Parliament introduced after a royal message on the subject. Up to 1857, when the title of Prince Consort was bestowed upon him by letters patent, the late Prince Albert possessed no distinctive title and no place in court ceremonial but such as was accorded to him by courtesy. An opposite instance was that of Ferdinand of Aragon, who, on his marriage to Isabella of Castile, became joint ruler of that country.

CONSPIRACY, legally defined, "a combination by two or more persons, by some concerted action, to accomplish an unlawful purpose, or to accomplish a purpose not in itself unlawful, by unlawful means." Some of the more important common law conspiracies were those to commit treason or sedition, to murder, to cheat and defraud and to injure another maliciously. The common law recognizes as an offense the agreement between the conspirators to do an unlawful act, and no overt act is necessary for the completion of the crime. Changes have been made in this holding of the common law by the laws of several of the States and by Federal legislation in the United States. Where the changes have been made it has been declared that an overt act was necessary to make the conspiracy a crime. Conspiracies are ranked as misdemeanors, except such as by acts of legislation have been declared statutory conspiracies, and punishable as such, and they are ranked as felonies. Consult Bishop, 'New Commentaries on the Criminal Law' (Boston 1900); id., 'Commentaries on the Non-Contract Law' (Chicago 1889); also 'Encyclopedia of the Laws of England' (2d ed., London 1907).

CONSTABLE, Archibald, Scottish publisher: b. Carnee, Fifeshire, 24 Feb. 1774; d. Edinburgh, 21 July 1827. He was the original publisher of the *Edinburgh Review*, the poems of Sir Walter Scott, the 'Waverley Novels,' and other well-known works. In 1826, however,

the firm was compelled to stop payment, with liabilities exceeding $1,250,000. Sir Walter Scott, who was heavily involved, practically sacrificed his life in the endeavor to meet his creditors. Constable himself did not long survive his misfortunes. He became publisher of the *Scots' Magazine* (1801) and of the *Edinburgh Review* (1802), and owner of the *Encyclopedia Britannica* (1812), which he enlarged. He edited also a 'Chronicle of Fife' (1810) and wrote a 'Memoir of George Heriot' (1822). Consult Constable, 'Archibald Constable and His Literary Correspondents' (3 vols., Edinburgh 1873), and Lockhart, 'Life of Scott' (7 vols., London 1838).

CONSTABLE, Archibald, and His Literary Correspondents, a work by Thomas Constable (1873). It is the story of the Edinburgh publishing house which established the *Edinburgh Review;* initiated the publication of cheap popular volumes of literature, art and science; and by a bold liberality in payment of authors, with remarkable sagacity in judging what would succeed with the public, virtually transformed the business of publishing. In October 1802 the first number of the *Edinburgh Review* appeared. The generous scale of payment soon adopted — 25 guineas a sheet — startled the trade, and greatly contributed to make Constable the foremost among publishers of his day.

CONSTABLE, Henry, English poet: b. Newark, England, 1562; d. Liége, Belgium, 9 Oct. 1613. His chief work was his book of sonnets, 'Diana,' published in 1592, when few sonnets in the Italian form had been written. He was probably the author also of the 'Forest of Fancy' (1579), attributed to Chettle. Suspected of treason against Elizabeth, he was compelled to leave the country, and on his return in 1604 was confined in the Tower for a short time. His lyric 'Diaphenia' and his pastoral 'Venus and Adonis' take a high place in contemporary song.

CONSTABLE, John, English pastoral painter: b. East Bergholt, Suffolk, 11 June 1776; d. London, 1 April 1837. His father was a wealthy miller, and was at first desirous that his son should enter the Church, and then on finding him disinclined to this career, proposed that he should follow his own business. At the latter employment he continued for several years, but his favorite pursuit was painting, and in this he would occupy his leisure hours. After considerable objection on the part of his father, but encouraged by Sir George Beaumont, he entered as a student of the Royal Academy in 1799. For many years his progress as an artist was extremely slow. He did not sell a single picture to a stranger until 1814, but he had one or two private buyers who detected the promise of great things in his work. In 1816 he married secretly Maria Bicknell, who died in 1828. In 1819 his 'View of the River Stour' attracted some attention, and procured him admission as an associate of the Academy. His talent first received recognition abroad: he was awarded the medal at Lille in 1824, and another at Paris in the following year. Then followed his admission as a member of the Royal Academy (1826) — a tardy recognition which he did not value much. Constable's pictures are remarkable for the truth and vividness with which country scenes and natural phenomena are represented. Fuseli said of them that they made him call for his umbrella; and a French critic declared that his leaves and grass were bespangled with morning dew. He chose "unpicturesque" localities for his exquisite pastorals, and was the first to abandon the brown grounding adopted by the Dutch School for fresh and natural tints. For the first 12 years of his career he was able to develop along his own lines by having private buyers, and ever after that, it was by the inheritances to which he succeeded, not by what he earned, that he was enabled to live. Some authorities regard him as the founder of the impressionist school which culminated at Barbizon. Among the finest of his works are 'A View of Salisbury Cathedral'; 'The Cornfield'; 'The Lock'; and 'The Valley Farm.' Lately several good examples of Constable's art have been added to the Louvre, and the late Henry Marquand presented two fine pictures by him to the Metropolitan Museum of Art in New York. Consult Leslie, 'Memoirs of Constable' (1845); Wedmore, 'Studies in English Art' (1876–80); Brock-Arnold, 'Gainsborough and Constable' (1881); Chesneau, 'La Peinture Anglaise' (1882); Muther, 'History of Modern Painting' (1896); Holmes, C. J., 'Constable and his Influence on Landscape Painting' (New York 1903); and memoirs by Henderson, M. S. (1905), Tompkins (1907) and Fontainas (1927).

CONSTABLE (Lat. *comes stabuli,* count of the stable = master of the horse). 1. A great noble under the later Roman Empire, and so down through the Middle Ages; usually the commander-in-chief of the army; in France also of the navy, and the chief subject in the state, when Richelieu abolished the office in 1627. Napoleon revived the title but not the authority, and it lapsed with him. In England the lord high constable and the earl marshal held the courts-martial and courts of chivalry; but Henry VIII left the office unfilled, and it is only revived temporarily for great pageants. There were constables who were wardens of castles, and whose office is still existent, hereditary or appointive. 2. In England, a petty constable was the chief parish officer for keeping the peace, but is now mostly supplanted by the police. 3. In the United States, outside of cities and incorporated villages, the constable is still the chief conservator of the peace. The office was borrowed from England, and in colonial times was of high importance, including functions now assigned to various other officers. In New England he was appointed by the selectmen, in Virginia by the hundred, in other provinces or States chosen by the town. He not only made arrests, imprisoned, had right of search and executing processes, etc., but he was often tax collector, overseer of the roads, and even petty judge, and gave notice of town-meetings. There was no legally defined scope of his duties, each community deciding them for itself, but the place was always considered one of power and dignity. Philadelphia and New York had high constables, the latter up to about 1830, when his functions were given to the chief of police. The office of "constable of the commonwealth" has also been created in some States. Consult Bacon, 'New Abridgement of the Law'; Dalton, 'The Country

Justice: Containing the Practice, Duty and Power of the Justices of the Peace.'

CONSTANCE (Ger. *Constanz,* or *Konstanz,* ancient CONSTANTIA), Germany, city and lakeport in the state of Baden, occupying the only territory belonging to Germany on the south side of the Lake of Constance, at the place where that lake communicates with the arm known as the Untersee, "Lower Lake," and where the Rhine issues from it, 35 miles northeast of Zürich. It is 1,300 feet above sea-level. The chief edifices are a cathedral, the Kaufhaus, in which the famous Council of Constance sat from 1414 to 1418, and which deposed three anti-popes, and condemned Huss and Jerome of Prague; an ancient palace; a grand ducal residence. The city has manufactories of linen and cotton goods, carpets, chemicals and sacking. Constance is said to have been founded in 378 A.D. by Constantius Chlorus as a bulwark against the Alemanni. In the Middle Ages, when it reached the height of its prosperity (at the time of the Council it was able to receive 20,000 visitors), it was frequently called Kostnitz. It was annexed to the Austrian dominions in 1548, and to Baden in 1805. Pop. 31,252.

CONSTANCE, General Council of, the 16th ecumenical council of the Church, was held at Constance, Baden, Germany; it was presided over by Pope John XXIII, in its opening session 5 Nov. 1414, and was dissolved in its 45th session 1418. It was called at the suggestion of the Emperor Sigismund for the purpose of dealing with the Hussite heresy; of considering measures for the general reform of the Church, and of restoring peace to the Church, which was troubled with schisms owing to the rivalry of three claimants of the papal throne. There was Balthasar Cossa, styled John XXIII: his title seemed to be sound in point of law, but the man was eminently unfit for the office; then there was Petrus de Luna, styled Benedict XIII: he was a Spaniard, but was chosen by the French cardinals: his style, Benedict XIII, was formally disallowed when the Pope, Vincenzo Marco Orsini, who at first assumed the style of Benedict XIV (1724), afterward changed that to Benedict XIII; and there was Angelo Corario, styled Gregory XII: both of these had been condemned as perjured men, heretics and schismatics, by the Council of Pisa, which Council "deposed" them; but they still claimed papal honors. Besides the healing of these schisms, the Council was called to take measures for repression of Wiclifism in England and analogous heresies in Bohemia and elsewhere. Also the Council was to consider the ways and means of effecting a "reformation of the Church in head and members." In the Council were some of the eminent divines of the time, among them Pierre d'Ailly and Gerson, chancellor of the University of Paris, both sturdy advocates of reform; and also bishops representing the churches of England and Ireland. It is said that more than 18,000 priests, together with their retinues and many merchants and artisans, formed the brilliant crowd that collected in the city. John Huss, chancellor of the University of Prague, summoned to plead in the Council to the charge of maintaining the Wiclifite heresies, attended, having come under a safe-conduct of the Emperor Sigismund. The Council condemned the doctrines of Huss and ordered him to be given up to the civil power, to be dealt with according to the laws: he perished at the stake. Jerome of Prague met with the same fate. Memorable among the acts of this Council is its decision of a question submitted to the fathers regarding the succession to the sovereignty of the margraviate of Brandenburg. The Council recognized the superior validity of the claim of Conrad of Hohenzollern; from him is sprung the royal line of Prussia. The Council in the 12th session 29 May 1415 published a decree deposing John XXIII, who after a while formally resigned. In the 14th session Gregory XII (Corario) gave in his resignation. Petrus de Luna (Benedict XIII) refused to resign: but being no longer sustained by the king of Spain, he was simply ignored, and Cardinal Otto Colonna was elected Pope 11 Nov. 1417 under the style of Martin V. The schisms caused by the rival popes were ended. After a few reformatory measures, quite inadequate for the needs of the situation, were enacted, the Council was dissolved 22 April 1418. Consult Richtenthal, 'Kronik des Konziliums in Konstanz' (Augsburg 1553; Tübingen 1882); Creighton, 'A History of the Papacy during the Reformation' (London 1882); Wylie, 'The Council of Constance' (ib. 1900); Finke, H., 'Forschungen und Quellen zur Geschichte des Konstanzer Konzils' (Paderborn 1889); Valois, N., 'La France et le grand schisme d'Occident' (Vol. IV, Paris 1902).

CONSTANCE, Lake (anciently LACUS BRIGANTINUS; German *Boden See*), in central Europe, forming a common centre, in which Switzerland and the territories of Baden, Würtemberg, Bavaria and Austria meet. Length, northwest to southeast, 40 miles; greatest breadth, about 10½ miles; area, 204 square miles; greatest depth, 827 feet; 1,309 feet above sea-level. At its northwest extremity the lake divides into two branches or arms, each about 14 miles in length; the north arm is called the Überlingen Lake after the town of Überlingen, on its north bank; the south branch the Zellersee or Untersee. The Rhine enters the lake at Rheineck, at its southeast extremity, and leaves it at Stein, at its northwest termination. The lake, the waters of which are of a dark-green hue and very clear, are subject to sudden risings, the causes of which are unknown. In 1770 it rose in one hour from 20 to 24 feet above the ordinary level. It freezes in severe winters only. It is frequented by numerous aquatic birds, and contains a great variety and abundance of fish, including salmon, salmon-trout, pike and carp. The traffic on it is considerable, although its navigation by sailing vessels is rendered dangerous by sudden and violent squalls. There are numerous remains of lake dwellings on its shores. Steamers ply on the lake between Constance and various points on its shores. The principal towns are Constance, Bregenz, Friedrichshafen, Lindau and Rorschach. The land near is either flat or gently undulating, and fertile, and is covered with corn-fields, orchards and gardens, interspersed with ruined castles, and other remains of the Middle Ages, and with numerous towns and villages, producing altogether a very pleasing and striking effect.

CONSTANS, Flavius Julius, Roman emperor: b. about 320 A.D.; d. in Gaul 350 A.D. He was a son of Constantine the Great, and divided the empire after the death of his father with his brothers, Constantine II and Constantius II, receiving for his share Illyricum, Italy and Africa. Constantine, who invaded his provinces, having been slain in the battle of Aquileia, Constans became emperor of the whole West. He was weak, profligate and rapacious. His misrule caused an insurrection in Gaul under Magnentius; he fled to Spain, but was overtaken at the foot of the Pyrenees by the soldiers of the usurper, and slain. Constans protected the creed of Nice against the Arians and the Donatists, and closed the pagan temples.

CONSTANS, kôn'stäṅ', **Jean Antoine Ernest,** French statesman: b. Béziers, 3 May 1833; d. Paris 1913. He was a professor of law in 1876, when he was elected a deputy and affiliated with the Left Centre. He was Undersecretary of State in the Freycinet Cabinet in 1879, and was Minister of the Interior in the Freycinet and Ferry cabinets of 1880–81. After serving for one year as governor-general of Indo-China, he was compelled in 1888 to resign this position as incompatible with his duties as a deputy. From 1889 to 1892 he was again Minister of the Interior, and his vigorous measures served to overthrow Boulangerism. In 1897 he was elected to the Senate, and in the following year became Ambassador to Constantinople.

CONSTANT, kôn'stäṅ', **Jean Joseph Benjamin,** French portrait painter: b. Paris, 10 June 1845; d. there, 26 May 1902. He studied in the École des Beaux-Arts at Toulouse and Paris, and under Cabanel. A journey to Morocco in 1872 strongly influenced his artistic development. He has exhibited with growing distinction, at successive salons, from that of 1860, with his 'Hamlet,' his 'Samson' in 1872, his 'Scenes from Algiers' in 1873–74, his great historical painting of 'Mohammed II in 1453' in the Exposition of 1878, and in 1885 a large Oriental subject, as melodramatic as possible, with splendid rendering of the human figure and strong effects of color. Other noted canvases by him are 'Le roi du désert'; Le tigre favori'; and portraits of Mrs. Walters; Madame Calvé; Queen Victoria, exhibited in the Salon of 1901; Queen Alexandra; and De Blowitz. A good example of his portraiture is 'Mon Fils André' (Luxembourg), which took the medal of honor at the Salon in 1896. He was the fashionable artist of his time in Paris and London. His noble picture of 'Justinian' is in the Metropolitan Art Museum, New York. He was decorated with the Legion of Honor in 1878. He was a writer of repute, best known for his studies of contemporary French painters. Consult Stranahan, 'Modern French Painters' (New York 1893).

CONSTANT DE REBECQUE, dẹ-rẹ-bĕk', **Henri Benjamin,** French politician and author: b. Lausanne, Switzerland, 25 Oct. 1767; d. Paris, 8 Dec. 1830. His mother died at his birth and his father was an officer in the military service of Holland. He was brought up at Brussels at the home of Mme. de Nassau; studied at Erlangen in Franconia, and later at Oxford and Edinburgh where he met Mackintosh and became familiar with the government of the British Isles which he admired very much. Here he began his governmental studies in his paper 'Essai historique sur les mœurs des temps heroïques de la Grèce.' His ill health and general dissatisfaction with life caused him to leave England. He returned to Switzerland in 1786, where he remained but a short time, leaving for Paris in the following year. Here at the salon de Suard he met Mme. de Charrière, a woman of great mental powers, 27 years older than himself, with whom he formed a liaison which lasted for almost 10 years. A wild affair took him to England for a brief visit. After his return he became chamberlain at the court of Charles William of Brunswick. Here he married Mlle. Wilhelmine, Baroness of Chramm, a woman of little beauty but good intellect. His father became involved in political difficulties. The matter was finally settled satisfactorily with Benjamin's assistance and his father was not only exonerated but made a general. At this period Benjamin ventured on some new literary projects: 'Account of Corsica and Memoirs of Paoli' (1768), 'De la religion'; he undertook a comparison of the customs of the Greeks with those of the Celts, Germans, Scotch and Scandinavians. After Brunswick's manifesto against France, he divorced his wife (1794) and returned to Lausanne. He now entered upon a period of political restlessness and personal entanglements which consumed his entire life. At Lausanne he met Mme. de Staël, for whom he conceived a violent passion, and followed her to Paris in 1795. In the republican circle of which she was the centre, he soon became an important figure. He was a staunch supporter of the Directory and of a moderate republicanism. The consistent factor in his political life was his desire to see France a well-governed state. In defense of this he published his first political pamphlet, 'De la force du gouvernement,' in which he sought to induce all of the parties of the Directory to rally against the Counter-Revolution. This essay involved him in a duel with Bertin de Veaux,—one of a series of such encounters. In 1793 his title as a citizen had been contested on the ground of his Swiss birth, but his election as president of the canton of Luzarches and the reunion of Geneva and France in 1799 suppressed the question. About this time he formed the constitutional club of Salm, named after the hotel where it held its séances. It was formed to oppose the Royalist faction at the club of Clichy. In attempting to find a working middle ground, he joined forces with Barras and Talleyrand against Carnot and Barthelemy — a move which he regretted later. In 1799 he was made member of the Tribunate where he was attacked violently for his republican sentiments, which alienated the trust of Napoleon, and in 1802 he was finally eliminated. Mme. de Staël was held accountable for his republicanism, and she was also banished. Constant followed her to Germany, where her salon again became renowned at Coppet. He spent much time also at Weimar, where he became steeped in the religious and literary opinions of Schiller, Wieland, Schlegel, Müller and Goethe. He returned to Coppet in 1805; contracted a short liaison with Mme. Lindsay and eventually became married secretly to Charlotte de Harden-

berg in 1808. At this time he produced a tragic poem, 'Wallenstein,' after the manner of Schiller's trilogy. At Hardenberg he lived for a time with his wife's parents, where he worked on his book on religion. Here he was influenced by the spiritual mysticism of Herder, Cremer, Schleiermacher and Heeren, and his sceptical philosophy was lost. His father died in 1812. Constant continued his studies and published several political pamphlets attacking imperialism. At Hanover, he received a visit from the crown prince of Sweden who conferred on him the Royal Star. After the abdication of Fontainebleau he returned to Paris and at the salon of Mme. de Staël once more became an ardent publicist in behalf of liberal principles and freedom of the press. A series of pamphlets set forth his views on these subjects. During the One Hundred Days his political policy was decidedly weak. The return to Paris of Napoleon caused him to flee for a short time, but he soon returned, doubtless because of his unrequited passion for the famous beauty, Mme. Récamier, and had an interview with Napoleon who appointed him a Councillor of State. After Waterloo and the return of Louis XVIII he went to England, where he published 'Adolphe,' the first psychological romance. It is largely autobiographical. Mme. de Charrière and Mme. de Staël are the prototypes of the heroine. In 1816 he returned to Paris, where he founded two liberal journals in which he renewed his advocacy of freedom of the press and liberal constitutionalism. In 1819 he was re-elected to the Chamber of Deputies; and again in 1824 and 1827. Although ill and crippled, he took part in the coronation of Louis Philippe, and on 27 August was made president of the Chamber of Deputies. His position was weakened by the acceptance of 200,000 francs from the king for the payment of his gambling debts which he had accrued when the death of Mme. de Staël in 1817 had caused him to withdraw almost entirely from society. In 1830 he was presented to the Royal Academy, but was rejected. Constant's egoism and his amours prevented his political ability from reaching its highest point. His greatest contribution to his party lay in his persistent fight for the freedom of the press. He was a poor debater, but the brilliant forcefulness of his philippics minimized that fault. His speeches are collected in 'Discours' (2 vols., 1828); his essays on government in 'Cours de politique constitutionelle' (4 vols., 1817–20). His book on religion, 'De la religion considérée dans sa source, ses formes, et ses développements' (5 vols., 1825, 1831), is generally considered his best work. Consult Sainte-Beuve, 'Nouveaux lundis' (Vol. I, Paris 1863), and 'Portraits littéraires' (Vol. III, ib. 1864); Constant's own 'Cahier Rouge,' which contains his autobiography from 1767–87 (1907), and 'Journal intime' (1804–16, re-edited with 'Lettres à sa famille,' by D. Melegari, 1895); his letters to Mme. de Charrière and Mme. Récamier, edited by Mme. Lenormant (1882); Rudler, G., 'La jeunesse de Benjamin Constant' (1900); and 'Bibliographie critique' (1909); Scott, Geoffrey, 'Portrait of Zélide, with Postscript on Benjamin Constant' (New York 1927).

CONSTANTIA, a district in the province of Cape of Good Hope, South Africa, on the eastern and northeastern slopes of Table Mountain range, and distant from Cape Town seven miles. Constantia consists of only three estates, High, Great and Little Constantia, which have long been famed for the quality of the wines produced upon them. The wines are sweet wines of delicious aroma, both red and white. Consult Mrs. Trotter, 'Old Cape Colony' (London 1903).

CONSTANTINE (kŏn'stăn-tīn) **I,** Pope. He was elected in 708 and died in 714. The principal events of his reign were the submission of Felix, archbishop of Ravenna, to Rome; and Constantine's confirmation of the Quinisextan Council at Constantinople. There was also an anti-pope of this name, who usurped the holy office in 767.

CONSTANTINE I, Flavius Valerius Aurelius Constantinus, called the GREAT, Roman emperor b. Naissus, in Mœsia (Serbia), 27 Feb. 274; d. Nicomedia, 22 May 337. He was the son of the Emperor Constantinus Chlorus, and after the death of his father was chosen emperor by the soldiery, in the year 306. Galerius was very unwilling to allow him the title of AUGUSTUS, and gave him that of CÆSAR only. Constantine, however, took possession of the countries which had been subject to his father, namely, Gaul, Spain and Britain. He overcame the Franks, who had formerly overrun the territory of Gaul, made prisoners of two of their leaders, followed them over the Rhine, surprised and defeated them. He then directed his arms against Maxentius, who had joined Maximian against him. In the campaign in Italy he saw, it is said, a flaming cross in the heavens, beneath the sun, bearing the inscription, «*In hoc signo vinces*» (Under this sign thou shalt conquer). He accordingly caused a standard to be made in this form, which was called the *labarum*. Some days after this he vanquished the army of Maxentius, under the walls of Rome, and drove it into the Tiber. He then entered the city in triumph, set at liberty all whom Maxentius had unjustly imprisoned and pardoned all who had taken up arms against him. He was declared by the Senate chief, Augustus, and *pontifex maximus*. In the year 313, together with Licinius, he published the memorable edict of toleration in favor of the Christians. By this every one was allowed to embrace the religion most agreeable to his own mode of thinking, and all the property was restored to the Christians that had been taken from them during the persecutions. They were also made eligible to public offices. This edict marks the period of the triumph of the cross and the downfall of paganism.

Constantine had married his daughter to Licinius; but the latter, jealous of his fame, conceived a mortal hatred against him, which he displayed by persecuting the Christians. Both emperors took up arms and met in Pannonia 314 A.D. Licinius was defeated, but the conqueror granted him peace. He, however, renewed hostilities, was vanquished again, taken prisoner and put to death at Constantine's command. Thus the latter became, in 325, the sole head of the Eastern and Western empires. His first and chief cares were the establishment of peace and order, and the propagation of his religion. Many beneficial decrees were proclaimed by him. Among these were those which

abolished all the establishments of debauchery, ordered the children of the poor to be supported at his expense, gave permission to complain of his officers and promised that the Emperor would not only hear complaints, but compensate the complainants for injuries received, when they were proved to exist. He diminished the land-taxes and caused a new valuation of estates to be taken. The state treasury had always been enriched by the property of criminals; but Constantine spared the property of their wives and ameliorated the condition of their children. Death in prison, he said, was a cruel punishment for the innocent, and an insufficient penalty for the guilty; he therefore ordered all trials of prisoners to take place at once. He forbade the use of unwholesome dungeons and oppressive chains. He gave leave to sick persons, widows and orphans to appeal from the local magistrates, and refused this privilege to their adversaries. It had been customary for the heirs of a person deceased to divide his slaves among them; Constantine forbade the separation in these cases of husbands from their wives and of parents from their children. To the Christians he gave permission not only to erect churches, but to be remunerated for the cost of them from his domains. Amidst all the cares of government and the occupations of war he found leisure to assemble the Council of Arles, to put an end to the schism of the Donatists. The ecumenical council held at Nice, in Bithynia 325 A.D., was attended by him in person.

On 26 Nov. 329 he laid the foundations of a new capital of the Empire, at Byzantium, upon the Bosporus, in Thrace. The city of Byzantium had been almost entirely destroyed by Severus; it was rebuilt by Constantine, enlarged and adorned with open squares, fountains, a circus and palaces, and called by his own name. Constantine divided the Empire into four parts, governed by four prætorian prefects. Toward the close of his life he favored the Arians, to which he was induced by Eusebius of Nicomedia; and he even banished many Roman Catholic bishops. In the year 337 he fell ill in the neighborhood of Nicomedia, was baptized, and died after a reign of 31 years.

Constantine committed a great political error in dividing his empire among his three sons, Constantine, Constantius and Constans. His zeal for Christianity appears to have been excited not less by the knowledge that the religion which was embraced by a majority of the inhabitants of the Roman Empire must prevail, and that, of course, the strength of the government must be increased by protecting it, than by a wish to apply its consoling powers to the relief of a heavy conscience. He has been accused of inordinate ambition, excessive liberality and an Oriental fondness for parade. But he was brave at the head of his army, mild and indulgent in his intercourse with his subjects, the favorite of his people, the terror of his foes. He was fond of the sciences as well as of arms, and gave them his protection. He read much, and wrote nearly all his own letters. In Eusebius we find many proofs of his theological learning. Some of the martyrologists have counted him among the saints, and fix 20 May as his festival. The Greeks and Russians observe it upon the 21st of the same month. Among all the writers who have attempted to describe the character, influence and policy of Constantine, Gibbon, from the extent of his researches and the profoundness of his views, appears to deserve the first place, though his impartiality is more than doubtful. Consult Eusebius, 'Vita Constantini'; Gibbon, 'Decline and Fall of the Roman Empire'; Firth, 'Constantine the Great' (New York 1905); 'Cambridge Mediæval History' (Vol. I, ib. 1911); Fletcher, 'Life of Constantine the Great' (1852).

CONSTANTINE II, Flavius Claudius Constantinus, Roman emperor: b. Arles, Gaul, 7 Aug. 312; d. near Aquileia, Italy, 340. He was the eldest son of Constantine I, and received as his share of the empire, on the death of his father, Gaul, Spain and Britain. Being desirous, however, of possessing himself of the territory of his brother Constans, he invaded the latter's dominions, but was defeated and killed.

CONSTANTINE III, a son of the Emperor Heraclius: b. 3 May 612; d. 23 June 641. He reigned only a few months after his father's death.

CONSTANTINE IV, Flavius Constantinus, Emperor of the East; surnamed POGONATUS, or the BEARDED: d. 685. He was son of Constans II, whom he succeeded in 668. His two brothers, Tiberius and Heraclius, shared the title of Augustus, but had little or no share in the government, and toward the close of his reign Constantine IV, under the influence of suspicion, had them mutilated and put to death. Constantinople was unsuccessfully attacked by the Mussulmans in 672 and the six following years; and it was during these wars that the famous «Greek fire» was invented. He was unable to repel the attacks of the Bulgars who crossed the Danube and settled in the country which they still inhabit (679). Constantine convoked and took part in the sixth general council held at Constantinople, at which the doctrine of the Monothelites was condemned.

CONSTANTINE V, Emperor of the East: b. Constantinople 719; d. near Selymbria, Thrace, 14 Sept. 775. He was surnamed COPRONYMUS and succeeded his father, Leo the Isaurian, in 743. He sided with the Iconoclasts, who hurled down the images of the saints, and persecuted the followers of the Roman Catholic Church. The important result was that the Pope turned to Pepin, king of the Franks, for protection, and thus shifted the dependence of the popes from Constantinople. In spite of his religious persecutions, he was a splendid civic ruler, and did much to restore trade and commerce. He died in an expedition against the Bulgarians.

CONSTANTINE VI, Flavius Constantinus, Emperor of the East: b. 771; d. Constantinople about 797. He was son of Leo IV, whom he succeeded in 780. Being only 10 years old when his father died, his mother, Irene (q.v.), was his guardian and regent of the Empire. On arriving at a mature age he wished to assume the government himself; but Irene, made cruel by ambition, had him imprisoned. He escaped in 790, exiled his mother, recalled her, and finally, ruined by his licentious living, and despised by his subjects, Irene led a conspiracy against him. He was imprisoned and his eyes were put out by her order. With him the Isaurian dynasty died out. Consult Schlosser, F. C., 'Geschichte der bilderstürmen-

den Kaiser des oströmischen Reichs' (Frankfurt-am-Main 1812).

CONSTANTINE VII, Emperor of the East: b. 905; d. 15 Nov. 959. He was surnamed PORPHYROGENITUS (born in the purple), and succeeded Leo the Wise as sole ruler in 945. He was destitute of energy, and devoted himself chiefly to study and the patronage of arts and letters. He admitted colleagues to the throne so that at least five emperors were reigning together. He was poisoned by his son Romanus in 959. Constantine VII left a treatise on state affairs, a geography of the empire and the 'Life of the Emperor Basilius, the Macedonian.' Several important works, to which we are indebted for historical knowledge, undertaken at his instigation, were 'Historica,' 'Basilica,' 'Geoponica' (agricultural treatises), 'Iatrica' (medical handbook), 'Hippiatrica' (on veterinary surgery), 'Historia animalium,' a compilation of Aristotle's views on the subject by Aristophanes of Byzantium, with additions from other writers. Consult Migne, 'Patrologia Græca' (cix, cxii, cxiii); Rambaud, A., 'L'Empire grec au dixième siècle' (1870).

CONSTANTINE VIII, Emperor of the East: d. 1028. He was the son of Romanus II, succeeded John Zemisces, and was proclaimed emperor of the East, with his brother, Basil II, who held the principal authority till 1025, when he died. Constantine VIII was, after that, sole emperor.

CONSTANTINE IX, surnamed MONOMACHOS, was emperor from 1042–55. He owed his position to his marriage with Zoë, the widow of Romanus III, who became empress in 1041. His reign was occupied with rebellions both at home and abroad. He had to wage war against the Turks, the Normans, the Patzinaks and the Russians.

CONSTANTINE X, DUCAS, emperor from 1059–67: b. 1007; d. 1067. He was the husband of Eudoxia. He succeeded Isaak Comnenus, whose friend and minister he had been. He was unsuccessful in repelling the attacks of the Normans in Italy and of the Turks and Magyars as well, and thus lost large portions of the kingdom. He besieged the Russians in 1043. A plague was more effectual in resisting the encroaching enemies.

CONSTANTINE XI, Palæologus, DRAGATSES or DRAGOSES, Emperor of the East: b. 1394; d. 29 May 1453. He was the son of Manuel II and the last of the Greek emperors, succeeding to the throne in 1448. His wife, Helena, was of the dynasty of Palæologus. He took possession of Morea and of much of the Peloponnesus and defeated the Turks in many battles. In 1446 Murad II forced him to surrender the Peloponnesus again. He was killed in bravely defending Constantinople against Mahomet II, who in 1453 besieged the city with 300,000 men. The heroic valor displayed by Constantine XI in this unequal contest demands our admiration; but valor was of no avail, the city was taken by storm, and thus ended the Greek Empire. Consult Mijatovich, 'Constantine, the Last Emperor of the Greeks' (London 1892).

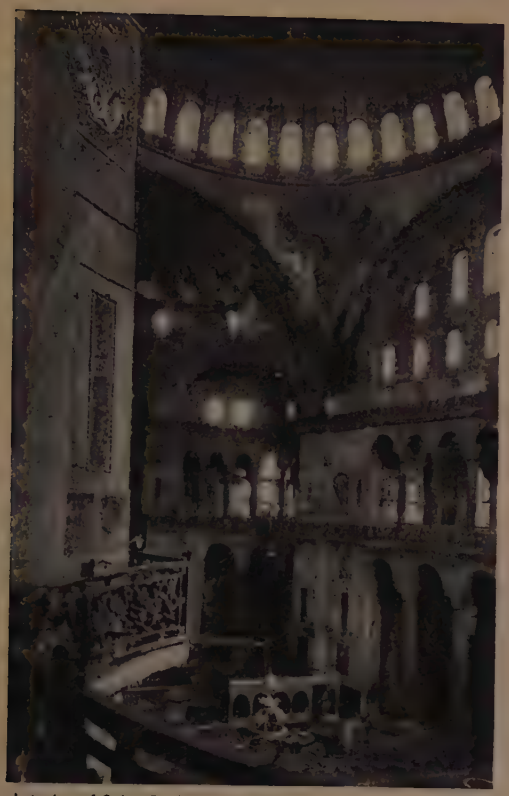
CONSTANTINE, Nikolaevitch, Russian grand duke: b. Saint Petersburg, 21 Sept. 1827; d. there, 24 Jan. 1892. He was the second son of the Emperor Nicholas of Russia, and brother of the Emperor Alexander II, grand duke and great admiral of Russia. In the war of 1854–56 he had the defenses of the Baltic entrusted to his care, in conjunction with Admiral Lütke; but the policy of the emperor hardly allowed the prince any display of courage or ability. He supported his brother's liberal reform plans and worked earnestly for the enlightenment of Russia. He was made viceroy of Poland in 1862, but resigned next year. He was president of the council of state 1865–81, but being suspected of sympathizing with the revolutionary party was dismissed from office. When Alexander III became king, he removed his uncle from all of his important offices, and Constantine retired to the Crimea.

CONSTANTINE, Pavlovitch, Russian grand duke: b. Saint Petersburg, 8 May 1779; d. Vitebsk, 27 June 1831. He was the second son of the Emperor Paul of Russia, and with his brother Alexander was brought up under Catharine II. In the wars against France he distinguished himself by his personal bravery, though not by his capacity for command. He was the elder brother of Emperor Nicholas, to whom he ceded the crown on the death of Emperor Alexander I, their brother. Constantine was afterward made viceroy of Poland, and ruled that unfortunate country with great severity. Poland revolted in 1830 and he was obliged to flee. He died of the cholera.

CONSTANTINE, Africa, town in the French territory of Algeria, capital of the department of Constantine, on a rocky peninsula, 2,162 feet above the sea, 830 feet above the river Rummel, which washes it on two sides, and accessible only on one side. It is surrounded by walls, built by the Arabs chiefly with stones which the Romans had hewn and carved, and is entered by four handsome gates. The streets, though well paved, are narrow and dirty, and the houses are very indifferent. The only edifice deserving of particular notice is the palace of the bey, now the residence of the French governor. It is more remarkable for its internal decorations than for its external structure. Both within the town and in the vicinity Roman remains abound. It is the episcopal see of a Catholic bishop. The modern or French portion has wide streets and open squares. Its principal buildings are the Palais de Justice, administration buildings, the Protestant church and a theatre. The French have here a college and the Mohammedans a seminary. The manufactures consist chiefly of woolen and linen goods and various articles in leather; the trade is in corn, linen and wax. It is connected by railroad with Philippeville, its port of entry, 47 miles distant, and with the largest towns in the territory. Constantine was built by the emperor whose name it bears, on the site of Cirta, the capital of the Numidian kings, which had fallen into decay. In 1837, after a long siege, the French took it by assault. Pop. 93,700.

CONSTANTINE, Arch of, one of the noted triumphal arches of the world, erected by order of the Roman Senate to commemorate the victory gained by Constantine over Maxentius. It is situated between the Cœlian and Palatine Hills, and was built in 315. This monument of victory is well preserved, but

CONSTANTINOPLE



Interior of Saint Sophia; formerly a mosque, now a museum.

View of Constantinople (Istanbul) and Galata Bridge.

while it tells of the power of the Emperor Constantine, it also bears witness to the incompetency of the Roman sculptors of the period in which it was built. The whole design was copied from the Arch of Trajan, even the reliefs were removed to the Arch of Constantine, and they illustrate the battles and victories of Trajan and not of Constantine. The parts copied or taken from Trajan are of superior design and workmanship, but the sculpture of the artists of the day, representing the deeds and victories of Constantine, are inferior in design and crude in workmanship. Four stately columns are on each face, one high and two lower entrances. The inscriptions proclaim the great deeds of the emperor. The arch was left standing in the Middle Ages probably because it was built by a Christian emperor. Consult Platner, 'Topography and Monuments of Ancient Rome' (New York 1911); Frothingham, 'The Mystery of the Arch of Constantine Unveiled' (in the *Century Magazine* for January 1912); Frothingham, 'Who Built the Arch of Constantine?' (in *American Journal of Archeology,* 2d series, Vols. XVI, XVII, 1912–13).

CONSTANTINOPLE, Turkey («the city of Constantine»), called *Istanbul* by the Turks (corrupted into *Stamboul*), from the Greek *eis tēn polin,* to the city; in official Turkish formerly «Constantinieh»: former capital of Turkey, situated at the junction of the Bosporus and the Sea of Marmora, in lat. 40° 0′ 16″ N., long. 28° 59′ 14″ E. It is practically an agglomeration of three towns, Stamboul, Galata-Pera and Skutari, besides a number of suburbs scattered for a distance of 12 miles along both sides of the Bosporus. The two first-named are on the European shore, divided by the Golden Horn, an inlet of the Bosporus about 500 yards wide and nearly six miles long.

Istanbul, or Constantinople proper, occupies the site of ancient Byzantium, built, like ancient Rome, on seven hills. The peninsula on which the city stands has the form almost of a triangle or, more correctly, of a trapezium, surrounded on all sides by water excepting the west, with a total waterfront of some 12 miles in extent. The eastern side projects into the Bosporus; the western forms a lofty double wall of five miles in length, stretching across the promontory from the Sea of Marmora to the Golden Horn; on the opposite side of the latter, also occupying the extremity of a promontory, sometimes called the Peninsula of Pera, are the extensive suburbs of Galata, Pera, Top Haneh and Kassim Pasha. Galata (formerly Sykæ = fig-trees) received its name from the Gauls who formed a settlement there. It is now the district where the banks, shipping agencies, stock exchange and offices of the representatives of European firms are established. Pera, adjoining Galata, is situated on the heights immediately above it, and is called the European or «Frankish» quarter. Here the Europeans, Levantines and most of the Greek and Armenian population live, and all the hotels, and foreign consulates are situated. Kassim Pasha is a dirty, insalubrious district around the dockyard, near which the Turkish fleet generally lies at anchor. Prominent on a plot of land stretching into the Golden Horn is the Admiralty, a fine marble building, and close by are the graving-docks, slips, building sheds and workshops. Directly above is the Naval Hospital. Opposite Kassim Pasha, on the Stamboul side, lies Phanar, a grimy suburb, inhabited mainly by Greeks. It is the seat of the patriarch and contains the Greek Cathedral of Saint George. Just beyond lies Balata, noted for its filthy condition, almost exclusively inhabited by Jews; the better class Jews live at Haskeui, on a hill opposite Balata, with a large percentage of Armenians. Farther up, on the opposite shore again, lies the village of Ayub (Eyoub), exclusively inhabited by Moslems; no Christians are allowed to hold property here. The spot is deeply revered by the faithful on account of the mosque built by Mohammed II, the Conqueror, in which each sultan was girded with the sword of Othman at the coronation ceremony. The adjoining burial ground contains the mausoleums and graves of numerous high personages. Skutari, properly «Usküdar,» over the Bosporus, stands on the site of ancient Chrysopolis; population, about 124,500. Its main objects of interest are the British and Turkish cemeteries and the convent of Howling Dervishes. The British Cemetery is the finest in Constantinople, and is situated at the Marmora end of Skutari, near Haidar Pasha. In it are buried many British soldiers who died during the Crimean War; one part was reserved for the interment of British residents. Adjoining the cemetery is the Skutari Hospital, once the scene of the devoted labors of Miss Florence Nightingale (q.v.) and her staff of British nurses. The Turkish Cemetery is the largest in Constantinople — a vast city of the dead — a wilderness of tombs — thickly planted with the funereal cypress. On a submerged rock off Skutari is the square lighthouse known as Leander's Tower, a name given to it by the Crusaders, though it has no connection with the legendary hero of that name. The Turks call it Kiz Kuleh, or the Maiden's Tower. It was first built as a mausoleum in 340 B.C., subsequently became a wooden lighthouse and was gradually replaced by a massive stone tower 90 feet high. Skutari has several theological colleges, schools, baths and a large Turkish printing-press, founded 1723. Haidar Pasha and Kadikeui, farther south, face the Sea of Marmora; the former is the terminal of the Constantinople and Angora Railway and a favorite Moslem picnic resort; the latter, standing on the site of ancient Chalcedon, is largely a European residential district, having all-day steamer communication with Galata. The other suburbs on the Asiatic side of the Bosporus above Skutari are, next, Kuzgunjik, a Jewish village where the Chief Rabbi resides; Beylerbey, exclusively Turkish, with a fine mosque and a white marble palace; the latter formerly contained the private menagerie of Abdul Aziz; Chengel Keui, a village; Kulehli, or Kuleh Bagtcheh (Garden Tower), where some 25 years ago Roman and Byzantine tombs, columns and marbles were unearthed; Vani Keui, founded 1665; Kandili, on the site of ancient Perirrhous; Anadoli Hissar (q.v.); Kanlija (bloody village), so named from the color of the rocks; Chibukli, where Saint Marcellus founded the monastery of the Order of Vigilants in 420 A.D.; Pasha Bagtcheh, notable for its fine mosque built in 1763; lastly, Beikos, the largest village on the Bosporus, with extensive vineyards and a palace built by Mehemet Ali

Pasha of Egypt. Crossing over to the European shore again and starting from Galata up the Bosporus, the following suburbs and places of interest included with Constantinople are Top Haneh (cannon building, i.e., gun foundry); Kaba Tash; Beshik Tash ("cradle-stone"), the tomb of Ghazi Khaireddin, "the terror of the Christians"; Orta Keui a large village the ancient Saint Phocas, containing great market-gardens, the Yeni Valideh Mosque, and residences of state ministers; near by is the former imperial residence, Yildiz Kiosk (q.v.); Kuru Chesmeh, a dirty village inhabited by Armenians and Jews, formerly the residence of Wallachian Hospodars; Arnaut Keui (q.v.), the Byzantine Michaelion; Bebek (q.v.), where the famous Robert College (q.v.) is situated; Rumeli Hissar (q.v.), the "Citadel of Europe"; Balta Liman, where the treaties of 1838, 1841 and 1849, relating to the Danubian tributary states, were signed; Boyaji Keui, a village; Emirghian, site of the ancient Kyparodis, famous for its cypress grove, mosque, marble fountain, college, summer residences and palaces; Stenia (q.v.); Yeni Keui, containing ambassadorial summer residences and magnificent villas of wealthy Levantines; Therapia (q.v.), the famous health resort; and Buyukdereh ("Great Valley"), also a summer resort for the wealthy, situated 11 miles from Galata.

Constantinople is far from being a beautiful city, yet its natural position and picturesque appearance combine to make it one of the most gorgeous sights in the world — at a distance, which in this case truly "lends enchantment to the view." No other city can claim to be situated on two continents, Europe and Asia; and certainly none has a more thrilling and romantic history. Poets, artists and authors have endeavored in song, color and prose to depict the vision of Constantinople from the deck of a vessel on a fine summer's morning. It resembles rather some enchanted city of the 'Arabian Nights' than a real town of stone, bricks and mortar. The seven low-lying hills covered with buildings of all descriptions down to the water's edge, painted in more colors than the rainbow can boast of, with white kiosks, marble palaces, cypress trees, minarets and cupolas piercing the heavens, with a background of soft blue Oriental sky and a foreground of the Sea of Marmora, in the limpid waters of which the town is reflected as in a mirror; the Golden Horn, crowded with shipping and bright with the flags of all nations; innumerable caïques (rowing and sailing boats) and steam launches bearing gaily-attired civilians and uniformed officials; the multitude of different languages and jargons that greet the ear, marking the dividing line between the poetic East and the prosaic West: all these make up a rare confusion of form, color and sound, land, sky and water, that create a lasting and indescribable impression on the mind. Gibbon was fascinated by the scene, "formed by Nature for the centre and capital of a great monarchy"; Aubrey de Vere wrote that "the view of Constantinople from the sea is the most splendid of all the pageants presented to the human eye by the metropolitan cities of the earth." More recently Dr. Edwin A. Grosvenor wrote, "In the word 'Constantinople' there is the blended magic of mythologic romance, history, and poetry . . . . . the queen city of the earth, seated upon a throne." He also calls attention to the remarkable fact that the same great parallel which encircles the globe between 40° 20′ and 41° 50′ in north latitude includes Constantinople, Rome, Madrid, New York and Chicago.

But the scene changes suddenly and painfully when the traveler steps ashore and proceeds to stumble along the narrow, dirty, wretchedly-paved alleys which do duty for streets, and climbs the rocky staircase leading from Galata to Pera. Until 1910 he had to pick his way cautiously among and over the countless mangy, half-starved pariah dogs which infested the town and lived on street garbage. These have since been captured by gypsies, conveyed in caïques to the isle of Oxia in the Sea of Marmora and left to devour each other. Noisy, vociferating *hamals* or porters shuffle along the streets staggering under heavy loads and shouting "wárda!" (look out!); donkey drivers and muleteers yelling at their animals; hawkers and pedlers shricking out the excellence and cheapness of their wares; vermin-ridden beggars thrust mutilated stumps of limbs under the pedestrian's gaze to evoke sympathy; while over all hovers the insufferable stench arising from heaps of garbage.

Population.—According to figures obtained in the official 1935 census the population of Constantinople was not more than 741,148. About half are Mohammedans and the rest Orthodox Greeks, Armenians, Jews, Europeans, Africans and Asiatics.

The climate is healthy on the whole but extremely variable, and unsuited for those suffering from pulmonary affections. The best time for visiting Constantinople is in April, May, September and October, before and after the hot season.

Walls.— Constantinople was formerly walled on all sides; very little now remains of the walls on the seaward sides, but those on the land side are still in a fair state of preservation and extend across the peninsula from Ayub to Yedi Kuleh (Seven Towers) on the Sea of Marmora, from which begin the Walls of Theodosius (3½ miles), a double line with a moat 64 feet wide and a breastwork 58 feet thick running between them. The moat is now divided into market garden plots. The inner wall is 36 feet high and was flanked by 116 towers, of which about 90, in a dilapidated condition, still remain. The outer wall is 31 feet high and 13 feet thick, and was flanked with 78 towers, most of which are still there. Fourteen gates led through the walls, seven being formerly used for military purposes. Of the Seven Towers, the Byzantine citadel, three were destroyed by earthquake in 1758. The place also served as a state prison. The main gates are the Golden Gate, Yedi Kuleh Kapu, Yeni Kapu (New Gate), Silivri Kapu, Mevlevi Hanch Kapu, Top Kapu (Cannon Gate), Eghri Kapu (Crooked Gate) and Edirneh Kapu (Adrianople Gate). Near the Golden Gate is the grave of Ahmed Kiupruli Pasha, who was hanged on his return from the capture of Candia after a 24 years' siege. Each of the gates is rich in historical associations, inscriptions and architectural embellishment. An excellent account of these is given in the Constantinople guide book of D. Coufopoulos (London 1895). Beyond Tekfur Sarai stand the Wall of Leo the

Armenian (813 A.D.) and the Wall of Heraclius (627 A.D.).

Mosques and Churches.— There are 379 mosques scattered over Constantinople and environs, all of them more or less distinguished by grandeur and beauty; but the most remarkable are the royal mosques, of which there are about 15, among the finest in the world. Of these the largest and most splendid is the Suleimanieh, situated on the northeast side of the city, and standing in the midst of a large square, surrounded inside by an arcade upon pillars of granite and marble. Next to it in extent, but of much older date, is the famous mosque of Hagia Sophia («Ayiah Sofia»), near the east extremity of the city, the pattern of almost every mosque in the land; its walls and domes, of which last it has 20 of equal dimensions, springing from the same level, and sustained by 12 huge columns, are encrusted with mosaics, forming various figures and devices. The court or open square in which it stands is paved with marble and shaded by fine plane-trees. It was restored by Italian and English architects in the 19th century by order of the sultan, and the layer of plaster removed by which the superb mosaics and frescoes that decorate its walls were covered. The mosque of Yeni Djami, known also as that of the Sultana Valideh, was built by the mother of Mohammed IV, and is esteemed one of the most magnificent in the capital. It is constructed of white marble and has two peculiarly elegant minarets, encircled by three galleries of richly perforated workmanship. The principal dome rests upon four lesser ones, which appear to lift it to the clouds. The celebrated mosque of Sultan Ahmed is noted for its vastness and its enormous columns, 75 feet in circumference. The minarets are of great beauty and ascend to an immense height. The mosque of Sultan Bayazid contains the finest courtyard in the city. A vast number of pigeons haunt its precincts. Rustem Pasha mosque is remarkable for its tile work. The church of Saint Irene is now used as a museum of ancient arms. Among its relics are the swords of Mohammed II and Skander Bey and an armlet of Tamerlane. The Mehemet Pasha mosque is supposed to be the ancient church of Saint Anastasia Pharmakolytria, of the 5th century. All the other mosques are much less in size than those described, but very much resemble them in plan and other features. All of them are encircled by splendid columns of marble, Egyptian granite or serpentine, and have massive and highly ornamented gateways and porches, and handsome courts and cisterns for ablution. The church of the Fountain of Life and the Blachernæ Church are Byzantine edifices still belonging to the Greeks.

Monuments, etc.— Among other historic monuments of Constantinople are the magnificent tombs of the sultans Selim II, Mahmud II, Suleiman the Great and Mohammed II; the obelisk of Theodosius, the Serpent Column, the Colossus in the Hippodrome, the Porphyry or Burnt Column, Marcian's Column, the Column of Theodosius II in the Seraglio and the Column of Arcadius; the Philoxenos and the Basilica water cisterns; the China Pavilion; the Hippodrome («At-Maidan» = Race Course), originally laid out by Septimius Severus on the model of the Circus Maximus in Rome, 1,300 feet long and 600 feet wide; the aqueduct of Valens; the fountain of Sultan Ahmed; and the fire towers of Galata and Stamboul. The National Museum of Antiquities contains a magnificent collection of treasures; of minor importance is the Museum of Ancient Costumes.

Palaces.—Besides the smaller palaces already mentioned, there are the Old Seraglio, the Dolma Bagtcheh and Yildiz Kiosk. The first of these, situated on the promontory named Seraglio Point, at the junction of the Bosporus and the Sea of Marmora, was for centuries the residence of the Byzantine emperors and Turkish sultans. It later contained the Treasury, the Imperial College of Medicine, the Mint, an art school and the Museum of Antiquities. The beautiful Dolma Bagtcheh Palace lies on the Bosporus, while Yildiz Kiosk, once the residence of the sultans, is a collection of palaces and other buildings. (See YILDIZ KIOSK and HAREM). The Cheragan Palace, also on the Bosporus, was destroyed by fire in 1910. It was built by Abdul Aziz, and here he committed suicide in 1876.

Bridges, Bazaars, etc.— Two iron pontoon bridges span the Golden Horn and connect Galata with Stamboul. They have each a draw to allow the passage of vessels. The bazaars are numerous; some are covered, others open. The covered bazaars have a somewhat mean appearance, resembling a row of booths at a fair, but the arrangement and manner of exposing the gay and glittering wares is sufficiently attractive. The principal or Great Bazaar consists of long avenues covered over with lofty arches of brick, lighted by apertures in the roof and branching off in different directions. The ceilings of the vaults, and various parts of the walls, are ornamented with painted flowers and devices. On each side of the passage are counters and stalls, with a wide passage between them, and on each counter sits the merchant, generally smoking his pipe or chibouk, with his crossed legs drawn under him. The bazaars, both the open and covered, are severally allotted to particular trades and merchandise; they are generally so crowded that it is difficult to pass through them. The numerous public baths in the city are mostly of marble, of plain exterior, but handsome and commodious within, with every accommodation and appliance requisite. They are divided into a number of circular rooms, lighted from above, and sufficiently spacious to admit a number of bathers at the same time. There are a vast number of coffee-houses and lodging-houses, called khans, dispersed throughout the city. The latter resemble immense stone barracks or closed squares. They are intended for the use of strangers during their temporary sojourn in the city, who may have an apartment here, with command of the key. Considerable modern improvements have been made in the commercial section of the city. Electric cars and telephones have been introduced. French and German waterworks companies provide water from reservoirs in the forest of Belgrade.

Industry.— The few manufactures of Constantinople are chiefly confined to articles in morocco leather, saddlery, tobacco-pipes, head gear, arms, perfumes, gold and silver embroideries, etc.; but its foreign commerce is considerable. The Golden Horn is deep, commodious, well sheltered and capable of contain-

ing 1,200 large ships, which may load and unload alongside the quays. It is usually crowded with vessels and light boats, and presents a lively, bustling scene. Among the imports are corn, iron, timber, tallow and furs from the Black Sea and Russia; cotton stuffs and yarn, woolens, silks, watches, furniture, jewelry, coffee, sugar, pepper and spices, spirits, etc. The exports consist of silks, carpets, hides, wool, goats' hair, madder, valonia, etc. In 1928 a tonnage of over 12,261,500 entered and cleared the port in 6,976 vessels.

History.— The city was founded, according to tradition, by a band of settlers from Megara under the leadership of Byzas, in 658 B.C., and received the name of Byzantium. It was in turn attacked by the Thracians, Bithynians, and even the Gauls; it was repeatedly invested by the Persians, who, during the campaign of Darius against the Scythians, compelled the town to surrender to Otanes, one of Darius's generals, and subsequently burnt it. After the battle of Platæa (479 B.C.) the Lacedæmonians under Pausanias took Byzantium from the Persians, and refounded the colony. Seven years later the town was captured by the Athenians; within 30 years it revolted and returned to its former allegiance. It was again besieged and taken by Alcibiades in 408 B.C. The Athenians remained in possession for three years when they lost the town again to the Spartans under Lysander. A few years later Xenophon with his 10,000 passed through it on their march from Persia. In 390 B.C. it was once more brought under the sway of Athens. Philip of Macedon laid siege to the city in 340 B.C., but the Athenians, roused by the fiery eloquence of Demosthenes against the Macedonian conqueror, came to the rescue. After repelling Philip of Macedon, Byzantium had to submit, some years later, to Alexander, who passed it on to his successors. On the death of Lysimachus the city regained — and maintained — its independence for a century, until the mighty power of Rome invaded the region of Thrace and the Hellespont.

In return for the assistance it rendered to the Romans in their wars with Macedon and Antiochus, the Senate conferred on Byzantium the status of a "free and confederate city"; it lost these privileges under the Emperor Vespasian, and became an ordinary provincial town in A.D. 73. In the struggle between Septimius Severus and Pescennius Niger for the Roman Empire, Byzantium espoused the cause of the latter, but was captured by Severus after a three years' siege, and reduced to ashes. A few years later, however, he rebuilt the city, and embellished it with porticoes, magnificent public baths and a hippodrome. During the civil wars which followed the abdication of Diocletian, the city fortifications were restored, and afforded refuge to Licinius after his defeat by Constantine at Adrianople in A.D. 323. Constantine then advanced on Byzantium, and, by means of constructing ramparts and towers as high as those of the city, finally succeeded in taking it.

The name "Byzantium" now disappears, and "Constantinople" takes its place. The city is also called "Roma Nova," or "New Rome," for it is raised to the dignity of capital of the Roman Empire, thanks to its geographical position, which alone is responsible for its vicissitudes and chequered fortunes. A new political centre was required for the reunited Empire; frequent wars with Persia, revolts of Asiatic nations, incursions of Scythians, troubles at Rome and a host of other considerations demanded that the capital should be transferred further eastward. Christianity was established, the city was dedicated to the Virgin Mary, and the foundations of Hagia Sophia were laid. The old capital was plundered of its art treasures to decorate the new, and a 40 days' festival inaugurated the second founding of the city. Immigration was encouraged, schools were built, liberal laws enacted and a bishop, afterward raised to the rank of patriarch, was appointed. Historic Church Councils were held on the Bosporus — in 337 A.D., against the Arian heresy; in 359, when 150 orthodox bishops added to the Nicene Creed; in 553; in 681, when Pope Agatho presided; and again in 870, to condemn the iconoclasts, and when the Emperor Basil attended.

But Constantinople was not destined to tread the path of peace and Christianity. The decline had set in; the fall was at hand, and a new star had risen in the East — Islam. The city had been attacked by the Huns in 450; again by the Huns and Slavs in 553, and by the Persians in 626. The Saracen conqueror, Moawiyah, besieged the walls for seven years, and finally abandoned the enterprise. A second invasion by the Saracens under Moslemah was repulsed in 718, and toward the end of the 8th century the hero of the "Arabian Nights," the redoubtable Calif Harun al Rashid, planted his standard on the heights of Skutari, but was drawn off by concessions. During the 9th and 10th centuries Constantinople was assailed by six invasions — from Bulgaria, from Hungary, and four times from Russia.

In 1096 the Crusaders, under Godfrey de Bouillon, passed on their way to Jerusalem. The fourth crusade turned aside from their holy purpose, and decided to take Constantinople, with the aid of the Venetian Republic. The plan succeeded, and Baldwin, Count of Flanders, the valiant leader of the Norman knights, was elected to the throne. This new dominion lasted 58 years, during which time a large European army held the city. The Latin rule collapsed when the Crusaders evacuated Palestine, and the Greek Empire was restored, with the assistance of the Republic of Genoa. In return for their aid the Genoese were granted exclusive rights in Galata, which they promptly surrounded with walls, behind which they claimed independence, and defied the emperor. A state of civil war ensued within the city, which was kept up till the final conquest by the Turks. Sultan Bayazid determined to obtain possession of Constantinople in 1396. He commenced this task, but had to leave it suddenly to defend his own territories against Tamerlane. Bayazid was defeated in that encounter, and taken prisoner, in 1402. Twenty years later, his grandson, Murad II, after delivering his country from the Mogul yoke, led his victorious army to the gates of Constantinople. The reigning emperor, John Palæologus, yielded to his demands, and purchased an alliance by a heavy annual tribute. Murad II was a true Moslem, and kept his engagements religiously. For the 30 years of his subsequent reign Constantinople was in-

sured against Turkish aggression. His son, Mohammed II, abrogated the treaty, and built a fort ("Cut-Throat Castle") on the European side of the Bosporus, which remains to this day. In 1453 Mohammed arrived with 60,000 horse and 20,000 foot. The city could only muster 7,000 defenders. After a desperate struggle of 40 days, the city was captured, and Hagia Sophia was converted from a Christian church into a Mohammedan mosque. The dust had claimed the Byzantine, the Roman and the Greek Empires, and the sword of Othman has held the city on the Bosporus against all comers for over four centuries and a half.

The more important historic events which have taken place in Constantinople since then may be briefly summarized. Peace was concluded there between Turkey on the one side and Venice, Spain and the Pope on the other, in 1540; another peace treaty between Turkey and Russia in 1700; and an abortive alliance between Prussia and Turkey against the ambitions of Russia and Austria. In 1821 a massacre of Greeks took place, in which the Greek Patriarch was hanged. The rising of the Janissaries and their complete annihilation occurred in 1826. In the same year 6,000 houses and many palaces were destroyed, whilst other serious conflagrations, as well as earthquakes, worked their havoc upon the city in 1714, 1755, 1808, 1883, 1890, 1893, 1894, 1908 and 1910. The most disastrous fire for a century broke out 31 May 1918 and in two days covered 2½ miles of old Stamboul, destroying over 5,000 houses, 20 baths, a dozen bazaars and as many mosques. Over 200,000 were left homeless.

It was in Constantinople, too, that the alliance between Great Britain, France and Turkey against Russia was concluded — a few weeks before the Crimean War broke out. In the winter of 1876–77 the Great Powers held a futile conference here with a view to settling the Eastern Question, but could not prevent the Russo-Turkish war which followed. In February 1878 the Russian army reached almost to the gates of the city, and forced the Treaty of San Stefano upon the Porte, while British warships lay at hand to prevent the capture of Constantinople. In 1909 Sultan Abdul Hamid II was deposed, and Shevket Pasha entered the city at the head of the Macedonian army and the new régime was announced. During the Balkan Wars of 1912–13 the Balkan Allies almost reached the walls of the city, and again in 1915 the French and British attempted to capture Constantinople by forcing the Dardenelles. See WAR, EUROPEAN. The New Turkish Republic set up its capital in Angora, thereby reducing Constantinople to a mere seaport and ending its 2,000-year status as a world capital.

Editorial Staff of The Americana.

CONSTANTINOPLE, General Councils of. The most important of these ecclesiastical councils were: the First, attended by 150 Eastern bishops, and held in 381 is reckoned as the second ecumenical council of the Church, the first being that of Nicæa in Bithynia, 325. Its president was at first Miletius, patriarch of Antioch, and after him Gregory of Nazianzus, then archbishop of Constantinople. The council, comprising only Eastern bishops, was not reputed ecumenical till after the Western Church had approved its decrees by express or tacit consent. The council defined the creed of the Church as opposed to the heresy of Arius and kindred heresies growing out of it, among them the heresy of Macedonius who denied the godhead of the Holy Spirit; hence to the creed called of Nicæa this council added the clause, "and in the Holy Spirit, the Lord and life-giver who proceedeth from the Father, who with the Father and the Son is together worshipped and glorified, who spake by the prophets." Not till a later date was added "and the Son" (in Latin filioque) to declare the procession of the Spirit from the Son also. The Second Council of Constantinople — the fifth ecumenical — was held in 553, with 165 bishops, all Eastern. The heresies it condemned had relation to the heresy of Nestorius, who held that there were in Christ two persons, a human and a divine. This council, at first regarded as Oriental, was later accepted as ecumenical. Vigilius, the Pope, refused to attend, and was excommunicated. The council was accepted by the emperor, and was generally received in the East, but was repudiated in the West. A schism resulted which lasted until the synod of Aquileia about 700. The Third General Council of Constantinople, held in 680, was presided over by legates of the bishop of Rome, Pope Agatho. The errors it condemned were those of the Monothelites (q.v.). It anathematized all Monothelites living or dead, especially Sergius and his successors, the former Pope Honorius and Macarius, the patriarch of Antioch. The banned sect fled to Syria where they formed the sect of the Maronites. It was the Sixth ecumenical council. The Quinisext Synod (692) was regarded as supplementary to the fifth and sixth ecumenical councils. Its work was legislative and its decisions were set forth in 102 canons. The synods of 754 and 815 set forth decrees against image worship. The Fourth General Council of Constantinople (the eighth ecumenical), held in 860, was convoked for the purpose of ending the schism then separating the Eastern from the Western Church. This council decreed the deposition of Photius, the usurping patriarch of Constantinople, and the restoration of Ignatius the rightful patriarch; but both this decree and the measures proposed by the council for reconciling the Eastern with the Western churches were repudiated by the Greek Church; and the schism grew wider and has continued, with an interval of communion now and again till the present time. pp. 210 seq.; XIV, pp. 111 seq., 787 seq.; XV, pp. 143–476; XVI, pp. 1–500; XVII, pp. 66–186, 365–530).

CONSTANTINOPLE, Strait of. See BOSPORUS.

CONSTANTIUS I, kŏn-stăn'shĭ-ŭs (full name FLAVIUS VALERIUS CONSTANTIUS; surnamed CHLORUS, "the pale"), Roman emperor: b. about 250; d. York, England, 306. Nephew of Emperor Claudius II, he became caesar in 292, and after re-establishing Roman power in Britain and defeating the Alemanni, he became one of the Augusti in 305. His son, Constantine the Great, succeeded.

CONSTANTIUS II (full name FLAVIUS JULIUS CONSTANTIUS), Roman emperor: b. Sirmium, 317; d. Cilicia, 361. The second son of Constantine the Great and Fausta, he was emperor of Rome from 337 to 361. Reigning first in the East, after the fall in the West of his two brothers, Constantine II and Constans, in 350, he fought against the usurpers. Constantius was victorious and ruled the whole empire. In 361 his cousin, Julian, was proclaimed emperor by the army. Constantius marched against him but died, and Julian succeeded him.

CONSTANTIUS III, Roman emperor: b. Illyria; d. Ravenna, September 421. He fought campaigns in Gaul and Spain, captured Constantine the Tyrant, and finally was made co-emperor of the West by Emperor Honorius. He married Galla Placidia, the sister of Honorius, in 417. He died after a reign of only a few months.

CONSTELLATION (Lat. *con,* with, *stella* star). From the earliest times men have classified groups of stars in constellations. Out of the 88 which are now recognized and which cover the whole sky, 48 were described by the Greeks before 400 B.C. Some are mentioned in the much earlier writings of Homer and Hesiod. There is, however, reason to believe that the Greeks, probably through the Phoenicians, acquired far more ancient astronomical knowledge from the Euphrates Valley, where some of the constellations seem to have been well known before 3000 B.C. Undoubtedly the brighter groups were recognized and named by nomadic peoples long before there were any written records.

Aratus of Soli about 270 B.C. gives us our oldest list of 44 constellations which he copied from a work by Eudoxus of about a century earlier. In those enumerated by Aratus, we have 19 northern constellations, 13 zodiacal, and 12 south of the ecliptic. Among the first, Ophiuchus includes the modern Serpens and Centaurus includes Lupus. We now count the Pleiades as merely an asterism and part of Taurus. Aratus gave, however, the three groups as follows: (1) Ursa Major, Ursa Minor, Draco, Cassiopeia, Cepheus, Perseus, Andromeda, Pegasus, Triangulum, Auriga, Boötes, Corona, Cygnus, Hercules, Lyra, Sagitta, Aquila Delphinus and Ophiuchus; (2) Aries, Pleiades, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Aquarius, Capricornus and Pisces; (3) Cetus, Eridanus, Orion, Canis Major, Lepus, Argo, Hydra, Crater, Corvus, Ara, Centaurus, and Piscis Australis. Many of these constellations bear names connected with the Argonautic expedition, so the legends connected therewith have been permanently immortalized. The first star catalogue, that by Hipparchus of about 129 B.C., has been lost; therefore, the catalogue by Ptolemy (Claudius Ptolemaeus) of 137 A.D. is the oldest in existence. This is contained in his classical *Almagest* (q.v.), the textbook of astronomy for the next 15 centuries. He gives 48 constellations, the names and approximate boundaries of which survive. He probably copied the earlier work of Hipparchus.

In 1603, Johann Bayer published his *Uranometria,* which contained 12 new southern constellations. These maps were decorated by a series of drawings, the outlines of which have served since to ornament the constellations as represented on many celestial globes and in many atlases. These were among the first star maps published, although Gerhardus Mercator had introduced stellar globes earlier. Bayer also introduced the great reform of designating the stars in a given constellation by letters of the Greek alphabet, arranging the stars thus in their approximate order of brightness. Before his day it had been usual to designate the star by its position in the figure of the object which the constellation was supposed to represent. Thus, Aldebaran (α Tauri) was the bright star in the eye of the bull. Bellatrix (γ Orionis) was the second magnitude star in the shoulder of Orion. The use of letters did away with this cumbersome and unscientific method of designation. When the 24 Greek letters ran out, Roman letters, and, later, catalogue numbers were used.

Attempts were made in the 17th century to rename the constellations, and even later, during the Napoleonic era, local efforts were made to rename Orion after national heroes. Fortunately all these impertinent and ill-conceived efforts failed. Edmund Halley in 1679 added one southern constellation, and in 1690 two posthumous works by Johannes Hevelius added 10, which are mostly inconspicuous. Crux, the Southern Cross, was added in 1679, and the present list was filled out by Nicolas Louis de Lacaille in his work which appeared in 1763, covering the far southern heavens. Unfortunately, Lacaille was more practical than poetic, so instead of immortalizing others of the ancient legends, he gave utterly prosaic names, such as Telescopium (telescope), Octans (octant), etc., to the newly named constellations. These names have survived.

The shapes of all the constellations are purely accidental and in only a few instances are the brighter stars contained in them arranged in such a manner as to bear the slightest resemblance to the object for which the constellation is named. Exceptions are Crux, Corona Borealis, and Scorpius. On the other hand, certain characteristic figures are obvious in the heavens, but they bear no relation to the constellation's name. For instance, we have the Great Dipper in Ursa Major, the Northern Cross in Cygnus, the Great Square in Pegasus, the Sickle in Leo, to mention only a few. Atlases also were not consistent, some placing a star in one constellation, others the same star in another. Perhaps the most flagrant case is that of α Andromedae which is also δ Pegasi. To remedy the confusion in the boundaries of constellations, and to secure a general agreement on what these boundaries really are, the International Astronomical Union appointed a committee, with Eugène Delporte as chairman, to bring in a full report. This dealt with all the 88 constellations of which 28 are northern, 12 zodiacal, and 48 are southern.

The report appeared in 1930. In the preface Delporte outlined the various previous attempts that had been made to secure a similar result, which is that the boundaries of constellations must follow in the north-south direction arcs of hour circles, and in the east-west direction arcs of declination circles. In 1879, Benjamin A. Gould in his *Uranometria Argentina* had succeeded in partially reforming some of the southern constellations. All attempts for the rest of the sky had failed until that supported by the International Astronomical Union, which is now universally adopted. The epoch chosen for the charts is 1875 to conform with Gould's work. They are so carefully drawn that no important star, bright or faint, is shifted from the constellation it formed part of, and from now on there will be no uncertainties as to the exact boundaries between constellations. This scientific reform fortunately will not prevent those who publish star atlases and desire to retain the old mythological figures, from tracing them in, as before. See also ASTRONOMY; STAR. Consult Upton, W., *Star Atlas* (Boston 1896); Delporte, E., *Délimitation Scientifique des Constellations* (London 1930); Barton, S. G., and Barton, W. H., *Guide to the Constellations* (New York 1944).

CONSTELLATION, a noted frigate of the United States Navy built in 1798 for service against the Barbary pirates. In the undeclared war with France she captured *L'Insurgente* (1799) and defeated *La Vengeance* (1800). Inactive during the War of 1812, she was in Decatur's Mediterranean squadron in the 1815 campaign.

CONSTIPATION, a condition in which the normal number of evacuations from the intestinal canal does not take place, or one in which the faeces are extremely hard and painful in passing. Constipation affects all ages, being prevalent in childhood, youth, adult life and old age. It can for the most part be regulated by proper hygienic living, but by reason of extreme carelessness in this regard is very prevalent.

The symptoms of constipation vary considerably. In infants there is always pain; the child cries, especially on attempts to defecate; there is usually much colic; there may be fever. In adult life the symptoms are fairly well marked. There is the time element, which is known; there is pain on passage, due to hardness of the faeces; and there may be feelings of bloating, coated tongue, headache or backache, all of which are characteristic of this condition. In fact the symptoms which are described very widely in patent-medicine circulars as due to disease of the kidney, brain, lost manhood and vague menstrual irregularities are the usual symptoms of ordinary constipation, and the patent-medicine business succeeds largely because it ascribes to this extremely common malady names of very much more dangerous illnesses. Practically most patent medicines are hardly more than cathartics.

The causes of constipation are in the main two—lack of water in the intestines and lack of muscular tone of the unstriped muscle of the intestinal walls. Lack of water may result from insufficient drinking of water. It may also result from increased elimination of water, as in excessive sweating. It may also be the result of diminished secretions of the normal juices of the intestines—the gastric juice, the bile from the liver and the pancreatic and intestinal juices.

These are all essential in adding fluid to the intestinal canal. Insufficient muscular power in the intestines may be due to a number of causes. Lack of tone of the body in general, resulting from insufficient exercise and insufficient food, is one of the most important. Bad dressing is a second cause for this loss of muscular tone. It may be a symptom of a nervous disorder such as is very frequently found in paraplegia, in locomotor ataxia and other grave spinal disorders, in which case the motor paralysis is more or less permanent. Lack of muscular power may also be the result of taking fluid diet; thus the intestine has less of the proper type of stimulus and the muscular power is not invoked. A frequent cause of constipation is tea-drinking. The most frequent cause of constipation is unconscious hate. This causes too much tension in the muscles of the lower bowel with the retention of the faeces.

The treatment of constipation is self-evident if one takes into consideration the two underlying causes and remedies them. The drinking of water, outdoor exercise, sunlight, the eating of food that has plenty of residue, such as bread, spinach, lettuce, cabbage, celery, etc.; these are very helpful. The first absolute necessity, however, in the treatment of constipation is to establish a habit of regular daily movement. In order to do this it is essential that a time should be taken which is ordinarily not interfered with, and the individual should consider a certain 15 minutes of the day to be sacredly devoted to this duty. So far as drugs are concerned in the treatment of constipation, they are best left alone; but if it becomes absolutely necessary that a drug should be used, it is a cardinal principle to remember that alternation of drugs is advisable. The same drug used day in, day out, and week after week, tends to diminish the power of the intestine and habituate it to a given drug. This results in some frightful cases of constipation. In a few cases of constipation in which the cause is due to some obstruction, as some solid body situated near the intestinal canal and pressing upon it, surgical treatment is imperative. The use of external massage is largely useless. The normal stimulus to muscular action comes from within—it is largely of unconscious nerve origin. It does not come from without. See CATHARTIC.

CONSTITUENT ASSEMBLY, a name given to the first convention of the delegates of the French nation (1787–91) to distinguish it from the Legislative Assembly of 1791. It drew up and obtained the acceptance of the first of the famous revolutionary constitutions. The constituent assemblies of 1848, 1945 and 1946 had similar aims. See ASSEMBLY, GENERAL; FRANCE—*History.*

CONSTITUTION, the fundamental law of a state, whether it be a written instrument of a certain date, as that of the United States of America, or an aggregate of laws and usages which have been formed in the course of ages, like the English Constitution. Its primitive meaning is that of any law given force by

proclamation and put into effect by the power of the supreme head of the government or nation.

I. Constitutions, according to their origin or their fundamental principle, may be divided into three classes: (1) Those established by the sovereign power; (2) those formed by contracts between nations and certain individuals whom they accept as sovereigns on condition of their complying with the terms of the contract; (3) those formed by a compact between different sovereign powers.

1. The first class may be again divided into: (*a*) constitutions established by a free sovereign people for their own regulation, of which sort is the Constitution of the United States; and (*b*) such as have been, in some instances, granted by the plenary power of absolute monarchs to their subjects, and which in theory are the voluntary gift of the beneficence of the ruler. These are called by the French *constitutions, octroyées,* from *octroyer,* to grant.

2. The second great class of constitutions mentioned above includes such as have been formed by a contract between the future ruler and the people. These are mutually binding on each party as long as the other fulfils his duty. Such, in a great degree, is the British Constitution.

3. Some constitutions are compacts between several sovereign powers. Such was the Constitution of the German Empire and that of the United Provinces of Holland, and such is also the Swiss Confederation. The Constitution of the United States, though the different States call themselves sovereign, proceeded, in point of fact, from the people of the United States collectively, as is apparent from the very beginning of the instrument: "We, the people of the United States," and not "We, the States." Moreover, the Congress, established by this Constitution, has rights and powers far exceeding those which other confederate but entirely distinct governments are wont to allow each other. The Constitution, in short, unites all the States into one nation, the government being called by all parties the national government. Governments entirely and virtually distinct from each other never would, however closely confederated, allow a government, particularly a national government, to be established over themselves. The Constitution of the United States is more than a mere compact between independent powers, yet less than the simple constitution of an undivided nation; it ought rather to be considered as forming one whole with the different constitutions of the States which have given up to the general government most of the rights of sovereignty, as that of making war and peace, coining, etc.

II. In regard to political principles, constitutions are: (1) Democratic, when the fundamental law guarantees to every citizen equal rights, protection and participation, direct or indirect, in the government, such as the Constitution of the United States and those of some cantons of Switzerland; (2) aristocratic, when the constitution establishes privileged classes, as the nobility and clergy, and entrusts the government entirely to them, or allows them a very disproportionate share in it; such a constitution as that of Venice, and such as, at one time, those of some Swiss cantons, for instance, Bern; (3) of a mixed character, to this latter division belonging some monarchical constitutions, which recognize the existence of a king whose power is modified by other branches of government of a more or less popular cast. The British Constitution belongs to this last division.

III. The forms of government, established by the various constitutions, afford a ground of division important in some respects; and, lastly,

IV. The principle on which a constitution establishes the representation, or the way in which the people participate in the government, furnishes an important means of classification: (1) Some allow the people to partake in the government without representation, as was the case in many of the small states of ancient Greece, and also in the ancient Roman republic, and is still the case in several of the small Swiss cantons, in which the whole people assemble and legislate; it being obvious that such a constitution can operate only where the number of citizens is very small, and even then will be almost always objectionable; (2) some are of a representative character; that is, all the citizens do not take an immediate part in the government, but act by their representatives; constitutions of this sort, either establishing a general and equal representation, as those of the United States; or connecting the right of representation with particular estates and corporations. The term representative constitution is frequently applied exclusively to the former by way of eminence.

V. Representative constitutions may be divided into: (1) Such as are founded on the union of the feudal estates, the clergy, nobility, citizens and peasantry, the two latter of which derive their right of representation from the charters of the ancient corporations; (2) such as establish the right of a general representation, like the American Constitution, and such as partake of both characters, like the British Constitution. Those of the first class either originated in feudal times or have been since copied from such as did. The feudal states were conglomerates of many heterogeneous bodies; and it was reserved for later ages to unfold the true principles of government, to separate the essential from the unessential and injurious, to give stability, distinctness and extent to principles before unsettled, indefinite and limited in their operation. See articles on the different countries of the world for information respecting their various constitutions.

CONSTITUTION, Framing of the. When the resistance to British rule in America began, independence was not its aim, and provisional governments only were established in the several colonies, temporarily to take the place of the English colonial governments, which had been suppressed. The several colonies jointly instituted the Continental Congress for the purpose of prosecuting the war. This Congress in June 1776 appointed a committee to frame an instrument of government. This was entitled the 'Articles of Confederation and Perpetual Union' (see CONFEDERATION, ARTICLES OF). It was not until 1 March 1781 that all of the States had finally signed it. Its defects were so numerous and serious that for a time it looked as if the Union would go to pieces. Several amendments were proposed and failed of adoption, chiefly because the approval of *all* States was necessary for an amendment.

By 1786 everything pointed to a speedy dissolution of the Union as it existed under the Articles of Confederation, when aid came from an unexpected quarter and quite by accident. This was the Annapolis Convention (q.v.), called to settle commercial disputes between Virginia and Maryland. The friends of efficient government dominated the convention; it had no authority but to regulate trade, but reported that nothing could be done under such a government, and recommended calling a fresh convention to amend it — the changes of course to be consented to by all the States. Congress issued the call for 14 May at Philadelphia; but a quorum (seven States, a majority) was not secured until the 25th. George Washington was appointed president; by 2 June four more States had come in, and on 23 July the New Hampshire delegation arrived. All were thus finally represented but Rhode Island, which was unalterably opposed to the scheme, and was the last to ratify the Constitution.

Three prime obstacles lay in the path of the convention: the small States' fear of the large, the one-crop States' fear of the national taxing power (and general tenacity of hold on the port dues by those which had ports) and the slave-trading States' determination not to have the business summarily stopped. The first, if not compromised, would have prevented any union at all, as the three "large States," Massachusetts, Pennsylvania and Virginia — New York then counting as a "small State" — were scattered through the line; commercial interests quite possibly might have created three confederacies, the New England, Middle and Southern; the slavery question would have created two, from New York to Delaware and from Maryland south. The first was assuaged by equal representation in the Senate; the second by the prohibition of taxing exports, with some other safeguards; the third by permitting the slave-trade for 20 years. These were three primary concessions which secured the votes of enough States to overlook the irregularity of the convention's title to create a new government, and join the Union under it; and without them there would have been no Union then, and most probably none now.

The first was by far the most difficult of all. The second and third could be and were cured by one or two single provisions, not difficult to draft nor very difficult to agree on; the first involved the very basic structure of the government, and cost a long struggle, great ingenuity and much doubt about ratification. The situation was this: The convention assumed as a basis of debate that the 11 States represented the following populations: Virginia, 420,000 (including three-fifths of the slaves, as with all the five Southern States); Massachusetts, 360,000; Pennsylvania, 360,000; New York, 238,000; Maryland, 218,000; Connecticut, 202,000; North Carolina, 200,000; South Carolina, 150,000; New Jersey, 138,000; Georgia, 90,000; Delaware, 37,000. New Hampshire with 102,000 came late, and Rhode Island with 58,000 held aloof altogether. The three largest States were regularly reinforced by the three southernmost, who were next to or mixed with huge and powerful Indian confederacies against which they would like to turn the entire national force, and therefore favored a strong government; this gave a pretty constant large State vote of six for a "national" system, where the weight should be in proportion to size, and a small State vote of five for a federative one, like the Confederation, where each State had one vote. This further involved that the latter should be a one-chamber system, since two houses each representing sovereign States equally would be an absurd duplication. These two irreconcilable propositions were embodied in what were called the "Virginia" and the "Jersey" plans.

The former, presented by Edmund Randolph 29 May, was intended to obliterate the States as bodies from the government almost entirely. It was, in substance, that the Congress should have two branches, membership in both proportioned to population, but the lower ones chosen directly by the people, the upper by the lower out of nominations by the State legislatures, the executive by both houses jointly; that Congress should have a veto on the State laws, and the President with a part of the judiciary a veto on those of Congress; that Congress might coerce delinquent States, and should legislate on all matters where State action would cause discord in the Union (that is, commerce and taxation); that new States might be admitted; that all the obligations of the Confederation should be assumed, that members of State governments should take oath to support the national government and that the new Constitution should be ratified by popular conventions instead of the State legislatures. A plan of Pinckney of South Carolina was in the same line. The committee of the whole, after debate and amendment, reported the amended bill favorably 13 June. The amendments had cut out the power of coercing the States, taken the veto from the judiciary and restricted it to the executive; made the executive's term seven years and not renewable, the senators' seven and the representatives' three; had the State legislatures choose the senators; and styled the new system a "national" government. Two days later, William Paterson of New Jersey presented the "Jersey plan," whose distinctive differences were that Congress should have but one chamber with each State voting equally, and should gain its revenue from requisitions as then, only having the power of coercing delinquent States. Coercion implied gaining a majority vote in an equal body to make war on one of the members, which would never have been granted. The other articles — that Congress should have the power of taxation and regulation of commerce and of coercing refractory individuals as well as States, also of deciding disputes as to territory, etc. — were no stronger than the weakest link; Congress was given some powers extra to those of the Confederation, but was given no whit more power to enforce them. What the Confederation had lacked was not privileges, but force. Paterson's plan otherwise was much like Randolph's. The convention in committee of the whole adhered to the latter.

Hamilton attempted to forward a plan by which the Senate was to be chosen for life by electors chosen by popular vote, the executive chosen for life by electors chosen by popular vote and the State governors to be appointed by the national government, with an absolute veto on the acts of the legislature. It found no supporters.

The first problem was to settle the basis of

power between the States. Under Randolph's plan, the Senate would have had 28 members, of which the three «large States» would have had 13; and the House 65, of which they would have had 26 — two-fifths of the latter and about half the former. Obviously they would be able, by a bargain with one or two of the smallest States, to choose the President and dictate the entire operations of the government. On the other hand, Paterson's plan was practically the Confederation plus more wind and paper decrees. The deadlock was absolute. John Dickinson of Philadelphia suggested consolidating the two plans, which was like consolidating a democracy and an autocracy. But on 21 June William Samuel Johnson of Connecticut proposed the «Connecticut plan,» the one finally adopted, making the States equal in the Senate and proportional in the House. His colleague, Ellsworth, supported him; but the vote on it showed a tie, five large to five small States, and Georgia's delegation divided. The question was referred to a committee of one from each State, which reported a compromise to win over the large States by restricting the power of originating money bills to the House, which they would control, and secure the slave States by counting in three-fifths of the slaves as a basis of representation. With the addition of the power to the Senate to propose amendments to money bills, the compromise passed after a hot debate. The two New York delegates left the convention in wrath.

Another point which had to be compromised was the power of Congress over commerce. As matters stood, not only could each State lay any duties it pleased, so long as it did not violate treaties already made or take national property, and therefore fill the Union with prohibitive barriers, but a State like New York could ruin its neighbor, New Jersey, and deal a crushing blow at western Connecticut, whose port it was. Further, several States were not agriculturally diversified, but had one great crop of tobacco, or rice, or naval stores — a severe tax on which would bankrupt the entire State. The first of these difficulties was met at the outset by the conditional power given to Congress to regulate commerce between the States; the second was acknowledged by the insertion of the prohibition to tax exports, as said. A «committee of detail» reported a draft Constitution 6 August. It had 23 articles (finally boiled down to seven); the President was to have one term of seven years, and be chosen by Congress; there was no Vice-President, and the Senate chose a president for itself. This was debated till 12 September, and amended to its present form. The slave-trading States were given their solatium in the shape of permission to continue the trade for 20 years, and the entire slave group were placated by the fugitive-slave provision; the Vice-President and the electoral system were added, and a restriction of Congressional control of commerce to a two-thirds vote stricken out. On 12 September a committee of five was appointed to revise its form, and the actual work was mainly done by Gouverneur Morris (q.v.). The next day it was reported back, after a few changes — the chief requiring only a two-thirds instead of a three-fourths vote to pass a bill over a President's veto — and accepted. A new convention to consider amendments proposed by the States was voted down; they must take or leave it as it stood. Of the 55 delegates present, only 39 signed. On 17 September the convention adjourned. The Constitution and the resolutions of the convention were transmitted to Congress, which on 28 September ordered them sent to the State legislatures for action. (For the amendments, and the consequent difficulties about ratification, see CONSTITUTIONAL AMENDMENTS, HISTORY OF). Only three States — New Jersey, Delaware and Georgia — ratified it unanimously; Connecticut, Pennsylvania, Maryland and South Carolina, by heavy majorities; Massachusetts, New Hampshire, New York (see FEDERALIST, THE) and Virginia by light ones, after a bitter and protracted struggle; North Carolina refused to ratify without many amendments and a bill of rights, and Rhode Island refused altogether till it was carried without her and she would have been shut out. There was great dissatisfaction, and only the commercial classes were heartily in its favor: John Adams said afterward that the Constitution was «extorted from the grinding necessity of a reluctant people.» See UNITED STATES — ARTICLES OF CONFEDERATION; UNITED STATES — FEDERAL CONVENTION OF 1787.

CONSTITUTION, Immutability of the. The Constitution of the United States is the product of a few great minds assembled in a brief convention. A great statesman (Gladstone) has termed it «the most wonderful work ever struck off at a given time by the brain and purpose of man.» This characterization has been accepted by all thinking men. There have been, indeed, cavils at some provisions, and speculative suggestions of alterations and improvements by individual minds; but the universal wonder is that the framers of the Constitution did so well; and that wonder was never so great as now at the close of a stormy century, littered with the wrecks of governments and nations and dynasties and constitutions.

The «given time»! The work was great, the difficulties many — most men then deemed them insuperable — and the work and its difficulties have had commentators and historians for 100 years or more; but will there be a single reader of this article who has noted how short a time it took to frame the Constitution? Has there been a single commentator or historian who has adequately shown how exceedingly brief the «given time» was? Less than a hundred working days measured it.

Moreover, the framers had had no means of previous personal communication by telegraph and almost none by mail; there were no stenographers or typewriters; there was, indeed, no clerical assistance; for the proceedings of the convention were secret and the clerical work was done by great men. When we see recent conventions with modern facilities for rapid work spending months in putting a few patches on existing State constitutions, we can best appreciate the ability of the men who in 85 working days forged the great compact of the people of the United States with themselves — a compact which has lasted more than a century substantially unchanged, which survived the storm of the greatest civil war of the modern world, which has expanded with an unforeseen and unprecedented expansion of inhabited ter-

ritory from a narrow strip upon the Atlantic seaboard to the shores of the Pacific, and which, notwithstanding changed conditions of life and thought, has grown steadily in the power of moral obligation and become more and more truly the «supreme law» of over 124,000,000 people.

As the time was brief, so were the framers few. The convention was composed of 55 members; the Constitution was signed by 39, including Washington; 51 members took part in the debates (according to the most complete report we have of them, the Journal of Madison), again including Washington. It is generally assumed that he took no part in the debates; but Professor Fiske has said in words which cannot be too often brought before the American citizen:

> It was suggested that palliatives and half measures would be far more likely to find favor with the people than any thorough-going reform, when Washington suddenly interposed with a brief but immortal speech, which ought to be blazoned in letters of gold and posted on the wall of every American assembly that shall meet to nominate a candidate or declare a policy or pass a law, so long as the weakness of the human nature shall endure. Rising from his President's chair, his tall figure drawn up to its full height, he exclaimed in tones unwontedly solemn with suppressed emotion: "It is too probable that no plan we propose will be adopted. Perhaps another dreadful conflict is to be sustained. If, to please the people, we offer what we ourselves disapprove, how can we afterward defend our work? Let us raise a standard to which the wise and the honest can repair; the event is in the hand of God."

Some of the 55 took no real part in framing the Constitution, and some were obstructionists. Their objections may have exercised a wholesome influence on the convention, but added much to the cares and perplexities of the greater men who assumed the responsibility and did the work. But whether we take the 39 members who signed the Constitution, or the 51 who took part in the debates, or the 55 who composed the convention, the number seems perilously small to be entrusted with the titanic task of founding for all time a great and growing and intensely active nation. Edmund Randolph, speaking of the time when the Articles of Confederation were framed, apologetically called it «the then infancy of the science of constitutions and of confederacies.» He might have said the same of the moment at which he was addressing the convention. Very little did the world then know of the science of constitutions or confederacies! He well summed up the new and added difficulties which confronted the convention, and which it must meet and overcome:

> The inefficiency of requisitions was unknown [to the framers of the Confederation] — no commercial discord had arisen among any States — no rebellion had appeared, as in Massachusetts — foreign debts had not become urgent — the havoc of the paper money had not been foreseen — treaties had not been violated; and perhaps nothing better could be obtained, from the jealousy of the States with regard to their sovereignty.

There were other difficulties which Randolph, like a tactful statesman, left unnoticed. At one end of the line of financial troubles Rhode Island stood intent on her great scheme of making fiat paper money the equivalent of gold and silver by imprisoning the citizen who charged more for a commodity in the one kind of money than in the other. At the other end of the line stood New York, with the greatest custom-house of the country, her chief source of revenue, which she would be called upon to surrender to the new Federal government as a part of the price she must pay for coming within the sovereignty of the Constitution. Virginia owned a vast territory which she must cede that it might become the public lands of the United States. Even in the greatness and authority of the men who composed the convention there were dangers and impediments. Three of the greatest proposed things would have defeated the great work: Franklin, the wisest member of the convention, proposed that the legislative power be vested in a single house, which would have been substantially the House of Representatives; Hamilton, the brilliant genius of the convention, advocated a government of which the President and the senators should hold office during good behavior, that is, for life; Madison, the most sagacious statesman in the convention, would have cast the responsibility of legislation on the judiciary by lodging a veto power in the Supreme Court. Any one of these provisions would have wrecked the Constitution before it was adopted; and any one of them, if it had been adopted, would have given us a government essentially different from that which we possess.

There is still another extraordinary fact connected with the framing of the Constitution which has received little if any attention, and substantially no comment. In the order of philosophical research the first subject of investigation would be the means or process by which the framers worked. A true philosopher, contemplating the clearness and conciseness of the Constitution, the masterly handling of the chief elements of the future government, the wonderful adaptation of insufficient means to a glorious end, would instantly exclaim, «Such a work is not born of the human mind completed! What was the secret process by which these great inventors attained their grand result»? And the philosopher would find, as he suspected, that even as the Constitution stands alone in the records of constructive statesmanship, so do the means and methods by which the convention did its work. It speaks badly for the century that none of the lesser conventions which have assembled frequently to experiment with State constitutions has done its work in the same way. In a word, there is nothing which equals the Constitution; there is nothing which approaches the patient, painstaking workmanship of the great convention.

At the beginning, propositions for consideration and discussion were tentatively placed before the convention in an *abstract* form. These propositions were embodied in 15 resolutions, which were immediately referred to the Committee of the Whole. They were taken up one by one, and considered and discussed and amended or rejected or adopted or postponed for later consideration. The abstract of a part of a single day's proceedings will give a clear idea of the way in which the convention worked:

Tuesday, June 5. Mr. Randolph's *ninth* proposition—*The national judiciary to be chosen by the national legislature* — Disagreed to — *To hold office during good behavior and to receive a fixed compensation* — Agreed to — *To have jurisdiction over offenses at sea, captures, cases of foreigners and citizens of different States, of national revenue, impeachment of national officers, and questions of national peace and harmony* — Postponed.

At the end of two weeks of such considera-

tion and discussion (13 June), the Committee of the Whole reported the conclusions which had so far been reached in the form of 19 resolutions. But everything was still abstract and tentative. No line of the Constitution had yet been written; no provision had yet been agreed upon. The 19 resolutions in like manner were taken up, one by one, and in like manner considered and discussed and amended or rejected or adopted or postponed. Other propositions coming from other sources were also considered; and so the work went on until 26 July, when the conclusions of the convention were referred to the Committee of Detail, and the work of reducing the abstract to the concrete began. The convention then adjourned to 6 August, to enable the committee to «prepare and report the Constitution.»

On 6 August the Committee of Detail reported and furnished every member with a printed copy of the proposed Constitution. Again the work of consideration began, and went on as before, section by section, line by line. Vexed questions were referred to special committees,—composed of one member from each State,—amendments were offered, changes were made, the Committee on Detail incorporated additional matters in their draught, until, on 8 September, the work of construction stopped. But not even then did the labors of the convention cease. On that day a committee was appointed, «by ballot, to revise the style of, and arrange, the articles which had been agreed to.» This committee was afterward known as the Committee of Style. It reported on 12 September, and the work of revision again went on until Saturday, the 15th. On Monday, the 17th, the end was reached, and the members of the convention signed the Constitution. Well might Franklin exclaim in his farewell words to the convention: «It astonishes me, sir, to find the system approaching so near to perfection as it does!» He had been overruled more than once in the convention; provisions which he had proposed had been rejected; provisions which he had opposed had been retained; but he was a great man and saw that a great work had been accomplished.

This article should treat of the Constitutional changes of the century. But the extraordinary fact is that from the framers' point of view there has been, with one trivial exception, absolutely no change in the Constitution of the United States. «Are there not 19 amendments,» it will be asked, and «do not the presidential electors vote for a President and Vice-president in a different way, and is there not an unwritten change in the Constitution by virtue of which the selection of Presidents has passed directly to the people, acting through their political national conventions?» All these questions may be answered generally in the affirmative; and yet the fact remains that from the framers' point of view there has been, with one trivial exception, absolutely no change in the Constitution of the United States.

The work of the great convention was the making of a government; and the government which the framers made has remained absolutely unchanged. Madison, who was a wary as well as sagacious statesman, carried the first 10 amendments through the first Congress at the first session to assuage public excitement and strengthen the new government and close the mouths of those who railed against it. He introduced into the 10th amendment a rule of construction which would not have been adopted by the convention—a clause which politically has created no little mischief during the passing years, but which under the necessities of judicial construction has amounted to nothing, namely, that powers not delegated or prohibited by the Constitution «are reserved to the States respectively or to the people.» The other provisions of the 10 amendments are little more than quotations from the Bill of Rights. The Constitution contained but few such declarations: that the writ of habeas corpus shall not be suspended; that no bill of attainder or *ex post facto* law shall be passed; that the trial of all crimes shall be by jury; that such trials shall be in the State where the crime was committed; that no attainder of treason shall work corruption of blood or forfeiture except during the life of the person attainted. The 10 amendments declare that Congress shall make no law respecting an establishment of religion or prohibiting the free exercise thereof, or abridge the freedom of speech, or the right of the people peacefully to assemble and petition the government for a redress of grievances, etc. (Article 1). They provide that no person shall be compelled to be a witness against himself, nor be deprived of life, liberty or property without due process of law; nor shall private property be taken for public use without just compensation, etc. (Article 5). These are great principles and noble sentiments, but their efficacy depends upon the rectitude of the government and the vigor and integrity of the people. No Congress would ever have dared to «make a law respecting an establishment of religion,» though there had been no Constitutional prohibition; and many an unfortunate citizen has lived and died with his claim for property taken for public use still unpaid, notwithstanding the Constitutional guaranty of «just compensation.» In a word, the 10 amendments served their temporary purpose; they have doubtless warned off Congress occasionally when in the heedlessness of the short session or in the heat of political excitement a legislative wrong might otherwise have been done; they have in a few instances secured the individual citizen, judicially, in his natural right to life, liberty or property; they continue to be a standing moral restraint upon the legislative and executive branches of the government; and they form a noble decalogue of great principles to be kept before the eyes of all American citizens; but, nevertheless, the judicial records of the century show that the government which the framers of the Constitution established would have moved on just as it has done, if these 10 amendments had never been proposed. The conscience and intelligence of the country have been the real safeguards of the citizen against injustice and oppression.

The Eleventh Amendment was caused by the extreme ground taken by the early Supreme Court in Chisholm v. Georgia, 2 Dall. 419, and the incipient rebellion of that State. Its purpose was to overrule that decision and to exempt a State from suit by a citizen. If Marshall had been upon the bench the decision would never have been made; and, singularly, it was overruled by the same court a hundred years afterward (Hans v. Louisiana, 134

U. S. 1). The Thirteenth, Fourteenth and Fifteenth Amendments grew out of the Civil War. They abolished slavery; they impose restraints upon State governments; they confer on some persons constitutional rights; they guarantee certain rights, privileges and immunities to citizens and persons; and they contain some provisions relating to representation in Congress. Much litigation has been caused by them; some statutes have been held constitutional and some unconstitutional; a larger proportion of representation has fallen to the Southern States; the guaranty given to all citizens of the right to vote without regard to "race, color or previous condition of servitude" is not absolutely effective, and the government of the United States moves on precisely as it did before.

It has been said herein that from the point of view of the framers of the Constitution their work has been changed in only one trifling particular. That change relates to election of the President, and was effected by the Twelfth Amendment. Under the Constitution as it originally stood each elector voted for two persons for President. He who should have the greatest number of votes would become President; he who might come next would be Vice-President. Under this provision, Mr. Lincoln, in 1861, would have become President, and Mr. Seward Vice-President. That is to say, the Republican electors, following the direction of their party, as expressed by the national convention, would have cast all their votes for Mr. Lincoln, and all but one for Mr. Seward. The purpose of the framers was a wise one: to secure for the country the two strongest statesmen of the party constituting for the time being the majority of the people, to fill the offices of President and Vice-President. No better plan could have been devised for obtaining a strong executive. We see a weak and modified application of the principle in national conventions when the defeated "wing of the party" is placated by being allowed to designate the candidate for Vice-President. But in 1801 there had been a tie, whereby the electors had failed to elect, and the election had gone into the House. If it had not been for that mishap, the Twelfth Amendment would not now exist; and if the original system had survived until the time of rapid communication by railroad and telegraph and better party organization, it is safe to say that it would now be in unquestioned operation. Political conventions would long ago have adopted its leading principle, and the struggle would have been as to which of the two strongest candidates should be first or second upon the ticket. The system would have given greater dignity to the office of Vice-President, and would have brought the possible importance of that office always before the eyes of the citizen. But whether we think well or ill of the original method, one thing is certain, that the only change made by the Twelfth Amendment is a trivial one of administrative detail. After all the changes this country has passed through in the last hundred years — changes in civilization, of territory, of population, of ideas, education and public convictions, and individual life — changes such as the world has never witnessed in one country or in one century, the only change made in the Constitution has been the paltry one of having the electoral vote cast in one form instead of in another.

The unwritten amendment of the Constitution, as it has been called, also relates to the selection of the President. It is said by some of the commentators, and indeed it is now generally believed, that the electoral colleges were intended to be "deliberative bodies." In one sense this is true — in the legal sense. The electors are not ministerial or administrative officers; they do not perform a specific work in a way determined by higher official authority; in legal contemplation the responsibility of their action rests upon themselves. But the framers of the Constitution never supposed that the electors would disregard the political pledges upon which they were chosen, or that the American people, either directly or through their State legislatures, would blindly choose electors to evolve a President out of their inner consciousness. On the contrary, they contemplated the successful candidates receiving the votes of "a majority of the whole number of electors," and they required the electors to vote "in their respective States," and to vote on the same day. If they had framed a provision requiring all of the electors to convene at the seat of the government in one body, and there in their own way and time proceed to choose a President, there would be good reason for saying that actual deliberation was intended; but they did not give to the electors one single power or attribute by virtue of which they could deliberate.

That very thing was attempted and the attempt failed. The question before the convention was, in effect: "Where shall the deliberative power to choose the President be vested when the formal casting and counting of the electoral vote fails to elect?" The answering propositions were, "In the Senate," or "In the House of Representatives." Then Spaight, of North Carolina, said that "he would prefer their [the electors] meeting altogether [all together] and *deciding finally*"; and he moved "*that the electors meet at the seat of the general government*"; and all of the States except North Carolina voted against it. The evidence is therefore both negative and positive — the convention did not invest the electors with the necessary powers and means for deliberation, and positively refused to do so; and refusal is conclusive of non-intent.

The idea that it was ever intended that the electors should nominate the candidate for whom they themselves should vote is a myth which has been unthinkingly reiterated by most eminent writers, but which does not rest upon a single fact. Nothing perplexed the convention more than the subject of the executive. Plan after plan was weighed and found wanting. The electoral system was late in coming to the front, and was the solvent of many difficulties. Hamilton early foresaw the inevitable, and proposed that "the selection be made by electors chosen by the people." Madison, later, said that the option before the convention "lay between an appointment by electors chosen by the people and an immediate appointment by the people"; and he at the same time said that "the electors would be chosen *for the occasion,* would meet *at once,* and proceed *immediately* to an appointment." It was as well understood then as it is now that they would but register the decree of the political power which appointed them. The internal evidence

of intent is even more conclusive. He who supposes that the framers intended *that 13 different bodies should convene in 13 different places at one time for one object and for one day, and that object the selection of the executive of a nation,* confesses a most superficial knowledge of the greatest constructive statesmen of their century and of the great work which they deliberately planned and built.

And what better could the framers of the Constitution have done? Wilson, who proposed «an election by the people,» was «almost unwilling to declare the mode which he wished to take place, being apprehensive that it might appear chimerical.» Gerry, «who liked the principle,» «thought the community not yet ripe»; he «was for waiting till the people should feel more the necessity of it.» Gouverneur Morris admitted «that difficulties attended this mode,» but thought that they would be «found superable.» Madison liked an election by the people best, but acknowledged «the disadvantage this would throw on the smaller States.» Ellsworth declared «the objection drawn from the different sizes of the States unanswerable.»

It has been a fashion of late to speak of the electoral system as curious machinery which may give rise to serious complications; but viewed amid the difficulties and conditions and limitations of 1787, there is no stroke of practical statesmanship in the Constitution more wise and ingenious. The choosing of candidates soon drifted into Congress; with the coming of the steamboat and the railroad it passed from the congressional caucus to national conventions; and yet, notwithstanding these radical changes of usage, the expansion of territory, the multiplication of States, and the unscrupulousness of political partisanship, there have been no more mishaps than are incident to any system of human device.

To foretell the future of the Constitution is to foretell the future of the American people. They will change before it is changed. As with Washington and Lincoln, the more we know of them the better they appear; so of the Constitution, the more we contemplate its trials the better it appears adapted to our national needs. With the growth of knowledge there has been a growth of reverence. The people will experiment with State constitutions and tear them up and experiment again, but when it comes to the Constitution — the great Constitution — there is a sturdy sentiment of «hands off,» and that sentiment is incomparably stronger now than it was at the beginning of the century. Judicial construction has moved backward rather than forward, and where Marshall left it, it stands, substantially, to-day.

The amendatory provision of the Constitution is an unbarred door which may be opened at any time. It was wise and prudent of the framers to leave it thus unlocked. But he who tries to swing open that door will find two things of which he did not reckon: first, a *vis inertia* in the ignorance and indifference of congressmen — in their doubts whether the amendments will be popular — in their absorption in lesser things; and, second, that there is always some one on the other side pressing back the door.

CHARLES C. NOTT,
Late Chief Justice Court of Claims.

CONSTITUTION, The, or OLD IRONSIDES (from the slightness of the injury her hull received in the fight with the *Guerrière*), one of the most famous vessels of the American navy, now fixed in Boston harbor. She was a 44-gun frigate of 1,576 tons; one of the six war vessels ordered by Congress early in 1794, on account of the Algerian piracies. (See BARBARY POWERS, U. S. WARS AND TREATIES WITH THE). During the wars against Tripoli she was Preble's flagship and in 1805 took part in three of the five bombardments off Tripoli.

When the War of 1812 broke out Hull started to join the New York squadron with her, 12 July; was cut off by a British squadron, including the *Guerrière,* but in a wonderful chase of three nights and two days outmanœuvred and escaped it. On 19 August, off Cape Race, she ran into and fought a battle with the *Guerrière,* a somewhat weaker English frigate which she left a total wreck after an engagement of 25 minutes, the English losing 79 of their crew, the Americans 14. The *Guerrière* was sinking and could not be towed into port; she was therefore blown up. Hull sailed into Boston with his prisoners, to such an ovation as few men have ever earned in so short a time. In less than 25 minutes of actual fighting he had lifted the despised American navy and nation to an equality with the proudest of the world; and drew from Great Britain such an explosion of rage and humiliation as it has never known before or since. Later the *Constitution* was made Bainbridge's flagship for a cruise against English commerce in the East Indies. On 29 Dec. 1812 it encountered the *Java,* Captain Lambert, off the coast of Brazil, and at 2.10 P.M. joined action. The *Constitution* had 54 guns, with 787 pounds of metal; the *Java* 47, with 568 pounds. The crews were 480 and 426. One of the fiercest of naval battles ensued for nearly two hours, in which the *Constitution's* wheel was shot away at the outset, making its navigation difficult, and the English vessel was the better sailer anyway. But the American gunnery was incomparably more intelligent and improved every opportunity for raking broadsides, while the British did not. As soon as the *Constitution* came to close quarters, she inflicted ruinous damage and frightful slaughter. The *Constitution* was taken into Boston for repairs; but before they were completed, Boston was closely blockaded, and she did not escape till New Year's Day 1814, under Capt. Charles Stewart. See UNITED STATES, WAR OF 1812.

In a cruise to the West Indies, Captain Stewart captured four prizes, with 24 guns and 76 men; one of them was the 14-gun schooner *Picton.* Again blockaded by a powerful British squadron she did not escape until 17 Dec. 1814. In 1815 she encountered two British vessels, the *Cyane* and the *Levant.*

The *Cyane* struck; the *Levant* temporarily escaped, but was overhauled by the *Constitution,* and surrendered also. The two ships had lost 35 killed and 42 wounded; the *Constitution,* 4 killed and 10 wounded. Cut off by a powerful British squadron at a neutral port whose neutrality the English treated with utter contempt, the *Constitution* and *Cyane* succeeded by fine seamanship in escaping, but the *Levant* was recaptured. In 1830 she was reported unseaworthy, and condemned to be broken up, but

Oliver Wendell Holmes published in the Boston *Advertiser* his thrilling poem 'Old Ironsides,' and the public clamor excited by it saved the noble vessel, which was rebuilt and again put in service in 1833. In 1855 she was laid up at the Portsmouth Navy Yard, but used sometimes as a training-ship; in 1877 was again partially rebuilt, and took her last trip across the Atlantic the next year. In 1897 she was roofed in at the Boston Navy Yard, and was used as a barrack ship, until 1925. She was restored by popular subscription in 1927–31 and in the latter year visited several ports on the Atlantic seaboard. Consult Hollis, 'The Frigate Constitution' (1900); Adams, Henry, 'History of the United States' (Vols. VI, VII, IX, 1900–01); Roosevelt, 'Naval War of 1812' (1882).

CONSTITUTION OF MATTER. See GASES, KINETIC THEORY OF; MATTER; MOLECULAR THEORY.

CONSTITUTION OF THE UNITED STATES, the governing instrument of the United States of America, adopted in 1787, when it took the place of the Articles of Confederation. (For details of its adoption see CONSTITUTION, FRAMING OF THE). Political discussion of the time played a much greater part in the compromises of this instrument than its provisions in turn exerted on political history in the following period, which to a surprising degree may be attached to only two clauses of the instrument and to these two simply because of their vagueness, and their mutually contradictory nature. Section 8 (18) in defining the powers of Congress adds the blanket provision of power, "to make all laws which shall be necessary and proper for carrying into execution the foregoing powers, and all other powers vested by this Constitution in the government of the United States, or in any department or officer thereof." The second historic clause occurs in the Amendments, where Article X reads: "The powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively, or to the people." The former is the famous elastic clause. In this accommodating provision interpreted radically, or conservatively, in the light of the Tenth Amendment all shades of political theory find proof-texts for their peculiar doctrines. So immediately upon the formation of the new government two political parties arose, the Democratic-Republican party, strict constructionists of the elastic clause, who limited the powers of Congress to the minimum and exalted State rights to the maximum, and the Federalist party in favor of a highly centralized government doing everything possible for and in the States. Around this fundamental difference may be grouped the great political questions up to and culminating in the Civil War, and to a less degree recent political discussions are based upon the same variance in interpretation of the Constitution, although neither party now holds to the strict construction theory as it was set forth by the early opponents of the Federalists. This change has been brought about very largely by practical experience of affairs, it being well known that the foremost strict constructionists who have come to the presidential chair were forced by the exigencies of administration to a broader exposition of the clause. This was notably the case in the administrations of Jefferson and of his immediate lieutenants and successors.

The text of the Constitution follows:

CONSTITUTION OF THE UNITED STATES

WE the people of the United States, in order to form a more perfect union, establish justice, insure domestic tranquillity, provide for the common defense, promote the general welfare, and secure the blessings of liberty to ourselves and our posterity, do ordain and establish this Constitution for the United States of America.

ARTICLE I

SECTION 1. All legislative powers herein granted shall be vested in a Congress of the United States, which shall consist of a Senate and House of Representatives.

SECTION 2. 1 The House of Representatives shall be composed of members chosen every second year by the people of the several States, and the electors in each State shall have the qualifications requisite for electors of the most numerous branch of the State legislature.

2 No person shall be a representative who shall not have attained to the age of twenty-five years, and been seven years a citizen of the United States, and who shall not, when elected, be an inhabitant of that State in which he shall be chosen.

3 Representatives and direct taxes shall be apportioned among the several States which may be included within this Union, according to their respective numbers, which shall be determined by adding to the whole number of free persons, including those bound to service for a term of years, and excluding Indians not taxed, three fifths of all other persons. The actual enumeration shall be made within three years after the first meeting of the Congress of the United States, and within every subsequent term of ten years, in such manner as they shall by law direct. The number of representatives shall not exceed one for every thirty thousand, but each State shall have at least one representative; and until such enumeration shall be made, the State of New Hampshire shall be entitled to choose three, Massachusetts eight, Rhode Island and Providence Plantations one, Connecticut five, New York six, New Jersey four, Pennsylvania eight, Delaware one, Maryland six, Virginia ten, North Carolina five, South Carolina five, and Georgia three.

4 When vacancies happen in the representation from any State, the executive authority thereof shall issue writs of election to fill such vacancies.

5 The House of Representatives shall choose their speaker and other officers, and shall have the sole power of impeachment.

SECTION 3. 1 The Senate of the United States shall be composed of two senators from each State, chosen by the legislature thereof for six years; and each senator shall have one vote.

2 Immediately after they shall be assembled in consequence of the first election, they shall be divided as equally as may be into three classes. The seats of the senators of the first class shall be vacated at the expiration of the second year, of the second class at the expiration of the fourth year, and of the third class at the expiration of the sixth year, so that one third may be chosen every second year; and if vacancies happen by resignation, or otherwise, during the recess of the legislature of any State, the executive thereof may make temporary appointments until the next meeting of the legislature, which shall then fill such vacancies.

3 No person shall be a senator who shall not have attained to the age of thirty years, and been nine years a citizen of the United States, and who shall not, when elected, be an inhabitant of that State for which he shall be chosen.

4 The Vice President of the United States shall be President of the Senate, but shall have no vote, unless they be equally divided.

5 The Senate shall choose their other officers, and also a president *pro tempore*, in the absence of the Vice President, or when he shall exercise the office of President of the United States.

6 The Senate shall have the sole power to try all impeachments. When sitting for that purpose, they shall be on oath or affirmation. When the President of the United States is tried, the chief justice shall preside: and no person shall be convicted without the concurrence of two thirds of the members present.

7 Judgment in cases of impeachment shall not extend further than to removal from office, and disqualification to hold and enjoy any office of honor, trust or profit under the United States: but the party convicted shall nevertheless be liable and subject to indictment, trial, judgment and punishment, according to law.

SECTION 4. 1 The times, places, and manner of holding elections for senators and representatives, shall be prescribed

in each State by the legislature thereof; but the Congress may at any time by law make or alter such regulations, except as to the places of choosing senators.

2 The Congress shall assemble at least once in every year, and such meeting shall be on the first Monday in December, unless they shall by law appoint a different day.

SECTION 5. 1 Each House shall be the judge of the elections, returns and qualifications of its own members, and a majority of each shall constitute a quorum to do business; but a smaller number may adjourn from day to day, and may be authorized to compel the attendance of absent members, in such manner, and under such penalties as each House may provide.

2 Each House may determine the rules of its proceedings, punish its members for disorderly behavior, and, with the concurrence of two thirds, expel a member.

3 Each House shall keep a journal of its proceedings, and from time to time publish the same, excepting such parts as may in their judgment require secrecy, and the yeas and nays of the members of either House on any question shall, at the desire of one fifth of those present, be entered on the journal.

4 Neither House, during the session of Congress, shall, without the consent of the other, adjourn for more than three days, nor to any other place than that in which the two Houses shall be sitting.

SECTION 6. 1 The senators and representatives shall receive a compensation for their services, to be ascertained by law, and paid out of the treasury of the United States. They shall in all cases, except treason, felony and breach of the peace, be privileged from arrest during their attendance at the session of their respective Houses, and in going to and returning from the same; and for any speech or debate in either House, they shall not be questioned in any other place.

2 No senator or representative shall, during the time for which he was elected, be appointed to any civil office under the authority of the United States, which shall have been created, or the emoluments whereof shall have been increased during such time; and no person holding any office under the United States shall be a member of either House during his continuance in office.

SECTION 7. 1 All bills for raising revenue shall originate in the House of Representatives; but the Senate may propose or concur with amendments as on other bills.

2 Every bill which shall have passed the House of representatives, and the Senate, shall, before it become a law, be presented to the President of the United States; if he approve he shall sign it, but if not he shall return it, with his objections to that House in which it shall have originated, who shall enter the objections at large on their journal, and proceed to reconsider it. If after such reconsideration two thirds of that House shall agree to pass the bill, it shall be sent, together with the objections, to the other House, by which it shall likewise be reconsidered, and if approved by two thirds of that House, it shall become a law. But in all such cases the votes of both Houses shall be determined by yeas and nays, and the names of the persons voting for and against the bill shall be entered on the journal of each House respectively. If any bill shall not be returned by the President within ten days (Sundays excepted) after it shall have been presented to him, the same shall be a law, in like manner as if he had signed it, unless the Congress by their adjournment prevent its return, in which case it shall not be a law.

3 Every order, resolution, or vote to which the concurrence of the Senate and House of Representatives may be necessary (except on a question of adjournment) shall be presented to the President of the United States; and before the same shall take effect, shall be approved by him, or being disapproved by him, shall be repassed by two thirds of the Senate and House of Representatives, according to the rules and limitations prescribed in the case of a bill.

SECTION 8. 1 The Congress shall have power to lay and collect taxes, duties, imposts and excises, to pay the debts and provide for the common defense and general welfare of the United States; but all duties, imposts and excises shall be uniform throughout the United States.

2 To borrow money on the credit of the United States;

3 To regulate commerce with foreign nations, and among the several States, and with the Indian tribes;

4 To establish an uniform rule of naturalization, and uniform laws on the subject of bankruptcies throughout the United States;

5 To coin money, regulate the value thereof, and of foreign coin, and fix the standard of weights and measures;

6 To provide for the punishment of counterfeiting the securities and current coin of the United States;

7 To establish post offices and post roads;

8 To promote the progress of science and useful arts by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries;

9 To constitute tribunals inferior to the Supreme Court;

10 To define and punish piracies and felonies committed on the high seas, and offenses against the law of nations;

11 To declare war, grant letters of marque and reprisal, and make rules concerning captures on land and water;

12 To raise and support armies, but no appropriation of money to that use shall be for a longer term than two years;

13 To provide and maintain a navy;

14 To make rules for the government and regulation of the land and naval forces;

15 To provide for calling forth the militia to execute the laws of the Union, suppress insurrections and repel invasions;

16 To provide for organizing, arming, and disciplining the militia, and for governing such part of them as may be employed in the service of the United States, reserving to the States respectively the appointment of the officers, and the authority of training the militia according to the discipline prescribed by Congress;

17 To exercise exclusive legislation in all cases whatsoever over such district (not exceeding ten miles square) as may, by cession of particular States and the acceptance of Congress, become the seat of the government of the United States, and to exercise like authority over all places purchased by the consent of the legislature of the State in which the same shall be, for the erection of forts, magazines, arsenals, dockyards, and other needful buildings; and

18 To make all laws which shall be necessary and proper for carrying into execution the foregoing powers, and all other powers vested by this Constitution in the government of the United States, or in any department or officer thereof.

SECTION 9. 1 The migration or importation of such persons as any of the States now existing shall think proper to admit, shall not be prohibited by the Congress prior to the year one thousand eight hundred and eight, but a tax or duty may be imposed on such importation, not exceeding ten dollars for each person.

2 The privilege of the writ of *habeas corpus* shall not be suspended, unless when in cases of rebellion or invasion the public safety may require it.

3 No bill of attainder or *ex post facto* law shall be passed.

4 No capitation, or other direct, tax shall be laid, unless in proportion to the census or enumeration hereinbefore directed to be taken.

5 No tax or duty shall be laid on articles exported from any State.

6 No preference shall be given by any regulation of commerce or revenue to the ports of one State over those of another; nor shall vessels bound to, or from, one State be obliged to enter, clear, or pay duties in another.

7 No money shall be drawn from the treasury, but in consequence of appropriations made by law; and a regular statement and account of the receipts and expenditures of all public money shall be published from time to time.

8 No title of nobility shall be granted by the United States; and no person holding any office of profit or trust under them, shall, without the consent of the Congress accept of any present, emolument, office, or title, of any kind whatever, from any king, prince, or foreign State.

SECTION 10. 1 No State shall enter into any treaty, alliance, or confederation; grant letters of marque and reprisal; coin money; emit bills of credit; make anything but gold and silver coin a tender in payment of debts; pass any bill of attainder, *ex post facto* law, or law impairing the obligation of contracts, or grant any title of nobility.

2 No State shall, without the consent of the Congress, lay any imposts or duties on imports or exports, except what may be absolutely necessary for executing its inspection laws; and the net produce of all duties and imposts laid by any State on imports or exports, shall be for the use of the treasury of the United States; and all such laws shall be subject to the revision and control of the Congress.

3 No State shall, without the consent of Congress, lay any duty of tonnage, keep troops, or ships of war in time of peace, enter into any agreement or compact with another State, or with a foreign power, or engage in war, unless actually invaded, or in such imminent danger as will not admit of delay.

ARTICLE II

SECTION 1. 1 The executive power shall be vested in a President of the United States of America. He shall hold his office during the term of four years, and, together with the Vice President, chosen for the same term, be elected, as follows:

2 Each State shall appoint, in such manner as the legislature thereof may direct, a number of electors, equal to the whose number of senators and representatives to which the State may be entitled in the Congress: but no senator or representative, or person holding an office of trust or profit under the United States, shall be appointed an elector.

3 The electors shall meet in their respective States, and vote by ballot for two persons, of whom one at least shall not be an inhabitant of the same State with themselves. And they shall make a list of all the persons voted for, and of the number of votes for each; which list they shall sign and certify, and transmit sealed to the seat of the government of the United States, directed to the president of the Senate. The president of the Senate shall, in the presence of the Senate and House of Representatives, open all the certificates, and the votes shall then be counted. The person having the

greatest number of votes shall be the President, if such number be a majority of the whole number of electors appointed; and if there be more than one who have such majority, and have an equal number of votes, then the House of Representatives shall immediately choose by ballot one of them for President; and if no person have a majority, then from the five highest on the list the said house shall in like manner choose the President. But in choosing the President, the votes shall be taken by States, the representation from each State having one vote; a quorum for this purpose shall consist of a member or members from two thirds of the States, and a majority of all the States shall be necessary to a choice. In every case, after the choice of the President, the person having the greatest number of votes of the electors shall be the Vice President. But if there should remain two or more who have equal votes, the Senate shall choose from them by ballot the Vice President. (This clause was changed by the Twelfth Amendment).

4 The Congress may determine the times of choosing the electors, and the day on which they shall give their votes; which day shall be the same throughout the United States.

5 No person except a natural born citizen, or a citizen of the United States, at the time of the adoption of this Constitution, shall be eligible to the office of President; neither shall any person be eligible to that office who shall not have attained to the age of thirty-five years, and been fourteen years a resident within the United States.

6 In case of the removal of the President from office, or of his death, resignation, or inability to discharge the powers and duties of the said office, the same shall devolve on the Vice President, and the Congress may by law provide for the case of removal, death, resignation, or inability, both of the President and Vice President, declaring what officer shall then act as President, and such officer shall act accordingly, until the disability be removed, or a President shall be elected.

7 The President shall, at stated times, receive for his services a compensation, which shall neither be increased nor diminished during the period for which he shall have been elected, and he shall not receive within that period any other emolument from the United States, or any of them.

8 Before he enter on the execution of his office, he shall take the following oath or affirmation:—"I do solemnly swear (or affirm) that I will faithfully execute the office of President of the United States, and will to the best of my ability, preserve, protect and defend the Constitution of the United States."

SECTION 2. 1 The President shall be commander in chief of the army and navy of the United States, and of the militia of the several States, when called into the actual service of the United States; he may require the opinion, in writing, of the principal officer in each of the executive departments, upon any subject relating to the duties of their respective offices, and he shall have power to grant reprieves and pardons for offenses against the United States, except in cases of impeachment.

2 He shall have power, by and with the advice and consent of the Senate, to make treaties, provided two thirds of the senators present concur; and he shall nominate, and by and with the advice and consent of the Senate, shall appoint ambassadors, other public ministers and consuls, judges of the Supreme Court, and all other officers of the United States, whose appointments are not herein otherwise provided for, and which shall be established by law: but the Congress may by law vest the appointment of such inferior officers, as they think proper, in the President alone, in the courts of law, or in the heads of departments.

3 The President shall have power to fill up all vacancies that may happen during the recess of the Senate, by granting commissions which shall expire at the end of their next session.

SECTION 3. He shall from time to time give to the Congress information of the state of the Union, and recommend to their consideration such measures as he shall judge necessary and expedient; he may, on extraordinary occasions, convene both Houses, or either of them, and in case of disagreement between them with respect to the time of adjournment, he may adjourn them to such time as he shall think proper; he shall receive ambassadors and other public ministers; he shall take care that the laws be faithfully executed, and shall commission all the officers of the United States.

SECTION 4. The President, Vice President, and all civil officers of the United States, shall be removed from office on impeachment for, and conviction of, treason, bribery, or other high crimes and misdemeanors.

ARTICLE III

SECTION 1. The judicial power of the United States shall be vested in one Supreme Court, and in such inferior courts as the Congress may from time to time ordain and establish. The judges, both of the Supreme and inferior courts, shall hold their offices during good behavior, and shall, at stated times, receive for their services, a compensation which shall not be diminished during their continuance in office.

SECTION 2. 1 The Judicial power shall extend to all cases, in law and equity, arising under this Constitution, the laws of the United States, and treaties made, or which shall be made, under their authority;—to all cases affecting ambassadors, other public ministers and consuls;—to all cases of admiralty and maritime jurisdiction;—to controversies to which the United States shall be a party;—to controversies between two or more States;—between a State and citizens of another State;—between citizens of different States,—between citizens of the same State claiming lands under grants of different States, and between a State, or the citizens thereof, and foreign States, citizens or subjects.

2 In all cases affecting ambassadors, other public ministers and consuls, and those in which a State shall be party, the Supreme Court shall have original jurisdiction. In all the other cases before mentioned, the Supreme Court shall have appellate jurisdiction, both as to law and fact, with such exceptions, and under such regulations as the Congress shall make.

3 The trial of all crimes, except in cases of impeachment, shall be by jury; and such trial shall be held in the State where the said crimes shall have been committed; but when not committed within any State, the trial shall be at such place or places as the Congress may by law have directed.

SECTION 3. 1. Treason against the United States, shall consist only in levying war against them, or in adhering to their enemies, giving them aid and comfort. No person shall be convicted of treason unless on the testimony of two witnesses to the same overt act, or on confession in open court.

2 The Congress shall have power to declare the punishment of treason, but no attainder of treason shall work corruption of blood or forfeiture except during the life of the person attainted.

ARTICLE IV

SECTION 1. Full faith and credit shall be given in each State to the public acts, records, and judicial proceedings of every other State. And the Congress may by general laws prescribe the manner in which such acts, records and proceedings shall be proved, and the effect thereof.

SECTION 2. 1 The citizens of each State shall be entitled to all privileges and immunities of citizens in the several States.

2 A person charged in any State with treason, felony, or other crime, who shall flee from justice, and be found in another State, shall on demand of the executive authority of the State from which he fled, be delivered up to be removed to the State having jurisdiction of the crime.

3 No person held to service or labor in one State, under the laws thereof, escaping into another, shall, in consequence of any law or regulation therein, be discharged from such service or labor, but shall be delivered up on claim of the party to whom such service or labor may be due.

SECTION 3. 1 New States may be admitted by the Congress into this Union; but no new States shall be formed or erected within the jurisdiction of any other State; nor any State be formed by the junction of two or more States, or parts of States, without the consent of the legislatures of the States concerned as well as of the Congress.

2 The Congress shall have power to dispose of and make all needful rules and regulations respecting the territory or other property belonging to the United States; and nothing in this Constitution shall be so construed as to prejudice any claims of the United States, or of any particular State.

SECTION 4. The United States shall guarantee to every State in this Union a republican form of government, and shall protect each of them against invasion; and on application of the legislature, or of the executive (when the legislature cannot be convened) against domestic violence.

ARTICLE V

The Congress, whenever two thirds of both Houses shall deem it necessary, shall propose amendments to this Constitution, or, on the application of the legislature of two thirds of the several States, shall call a convention for proposing amendments, which, in either case, shall be valid to all intents and purposes, as part of this Constitution, when ratified by the legislatures of three fourths of the several States, or by conventions in three fourths thereof, as the one or the other mode of ratification may be proposed by the Congress: Provided that no amendment which may be made prior to the year one thousand eight hundred and eight shall in any manner affect the first and fourth clauses in the ninth section of the first article; and that no State, without its consent, shall be deprived of its equal suffrage in the Senate.

ARTICLE VI

1 All debts contracted and engagements entered into, before the adoption of this Constitution, shall be as valid against the United States under this Constitution, as under the Confederation.

2 This Constitution, and the laws of the United States which shall be made in pursuance thereof; and all treaties made, or which shall be made, under the authority of the United States, shall be the supreme law of the land; and the judges in every State shall be bound thereby, anything in the Constitution or laws of any State to the contrary notwithstanding.

3 The senators and representatives before mentioned, and the members of the several State legislatures, and all executive and judicial officers, both of the United States, and of the several States, shall be bound by oath or affirmation to support this Constitution; but no religious test shall ever be required as a qualification to any office or public trust under the United States.

ARTICLE VII

The ratification of the conventions of nine States shall be sufficient for the establishment of this Constitution between the States so ratifying the same.

Done in Convention by the unanimous consent of the States present the seventeenth day of September in the year of our Lord one thousand seven hundred and eighty-seven, and of the independence of the United States of America the twelfth. In witness whereof we have hereunto subscribed our names,

Attest WILLIAM JACKSON Secretary.

Articles in addition to, and amendment of, the Constitution of the United States of America, proposed by Congress, and ratified by the legislatures of the several States pursuant to the fifth article of the original Constitution.

ARTICLE I

Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof; or abridging the freedom of speech, or of the press; or the right of the people peaceably to assemble, and to petition the government for a redress of grievances.

ARTICLE II

A well regulated militia, being necessary to the security of a free State, the right of the people to keep and bear arms, shall not be infringed.

ARTICLE III

No soldier shall, in time of peace be quartered in any house, without the consent of the owner, nor in time of war, but in a manner to be prescribed by law.

ARTICLE IV

The right of the people to be secure in their persons, houses, papers, and effects, against unreasonable searches and seizures, shall not be violated, and no warrants shall issue, but upon probable cause, supported by oath or affirmation, and particularly describing the place to be searched, and the persons or things to be seized.

ARTICLE V

No person shall be held to answer for a capital, or otherwise infamous crime, unless on a presentment or indictment of a grand jury, except in cases arising in the land or naval forces, or in the militia, when in actual service in time of war or public danger; nor shall any person be subject for the same offense to be twice put in jeopardy of life or limb; nor shall be compelled in any criminal case to be a witness against himself, nor be deprived of life, liberty, or property, without due process of law; nor shall private property be taken for public use without just compensation.

ARTICLE VI

In all criminal prosecutions, the accused shall enjoy the right to a speedy and public trial, by an impartial jury of the State and district wherein the crime shall have been committed, which district shall have been previously ascertained by law, and to be informed of the nature and cause of the accusation; to be confronted with the witnesses against him; to have compulsory process for obtaining witnesses in his favor, and to have the assistance of counsel for his defense.

ARTICLE VII

In suits at common law, where the value in controversy shall exceed twenty dollars, the right of trial by jury shall be preserved, and no fact tried by a jury shall be otherwise reëxamined in any court of the United States, than according to the rules of the common law.

ARTICLE VIII

Excessive bail shall not be required, nor excessive fines imposed, nor cruel and unusual punishments inflicted.

ARTICLE IX

The enumeration in the Constitution of certain rights shall not be construed to deny or disparage others retained by the people.

ARTICLE X

The powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively, or to the people.

ARTICLE XI

The judicial power of the United States shall not be construed to extend to any suit in law or equity, commenced or prosecuted against one of the United States by citizens of another State, or by citizens or subjects of any foreign State.

ARTICLE XII

The electors shall meet in their respective States, and vote by ballot for President and Vice President, one of whom, at least, shall not be an inhabitant of the same State with themselves; they shall name in their ballots the person voted for as President, and in distinct ballots the person voted for as Vice President, and they shall make distinct lists of all persons voted for as President and for all persons voted for as Vice President, and of the number of votes for each, which lists they shall sign and certify, and transmit sealed to the seat of government of the United States, directed to the president of the Senate.—The president of the Senate shall, in presence of the Senate and House of Representatives, open all the certificates and the votes shall then be counted;—The person having the greatest number of votes for President shall be the President, if such number be a majority of the whole number of electors appointed; and if no person have such majority, then from the persons having the highest numbers not exceeding three on the list of those voted for as President, the House of Representatives shall choose immediately by ballot, the President. But in choosing the President, the votes shall be taken by States, the representation from each State having one vote; a quorum for this purpose shall consist of a member or members from two thirds of the States, and a majority of all States shall be necessary to a choice. And if the House of Representatives shall not choose a President whenever the right of choice shall devolve upon them, before the fourth day of March next following, then the Vice President shall act as President, as in the case of the death or other constitutional disability of the President. The person having the greatest number of votes as Vice President shall be the Vice President, if such number be a majority of the whole number of electors appointed and if no person have a majority, then from the two highest numbers on the list, the Senate shall choose the Vice President; a quorum for the purpose shall consist of two thirds of the whole number of senators, and a majority of the whole number shall be necessary to a choice. But no person constitutionally ineligible to the office of President shall be eligible to that of Vice President of the United States.

ARTICLE XIII

SECTION 1. Neither slavery nor involuntary servitude, except as a punishment for crime whereof the party shall have been duly convicted, shall exist within the United States, or any place subject to their jurisdiction.

SECTION 2. Congress shall have power to enforce this article by appropriate legislation.

ARTICLE XIV

SECTION 1. All persons born or naturalized in the United States, and subject to the jurisdiction thereof, are citizens of the United States and the State wherein they reside. No State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any State deprive any person of life, liberty, or property, without due process of law; nor deny to any person within its jurisdiction the equal protection of the laws.

SECTION 2. Representatives shall be apportioned among the several States according to their respective numbers, counting the whole number of persons in each State, excluding Indians not taxed. But when the right to vote at any election for the choice of electors for President and Vice President of the United States, representatives in Congress, the executive and judicial officers of a State, or the members of the legislature thereof, is denied to any of the male inhabitants of such State, being twenty-one years of age, and citizens of the United States, or in any way abridged, except for participation in rebellion, or other crime, the basis of representation therein shall be reduced in the proportion which the number of such male citizens shall bear to the whole number of male citizens twenty-one years of age in such State.

SECTION 3. No person shall be a senator or representative in Congress or elector of President and Vice President, or hold any office, civil or military, under the United States, or under any State, who, having previously taken an oath, as a member of Congress, or as an officer of the United States, or as a member of any State legislature, or as an executive or judicial officer of any State, to support the Constitution of the United States, shall have engaged in insurrection or rebellion against the same, or given aid or comfort to the enemies thereof. But Congress may by a vote of two-thirds of each House, remove such disability.

SECTION 4. The validity of the public debt of the United States, authorized by law, including debts incurred for payment of pensions and bounties for services in suppressing insurrection or rebellion, shall not be questioned. But neither the United States nor any State shall assume or pay any debt or obligation incurred in aid of insurrection or rebellion against the United States, or any claim for the loss or emancipation of any slave; but all such debts, obligations and claim shall be held illegal and void.

SECTION 5. The Congress shall have power to enforce, by appropriate legislation, the provisions of this article.

ARTICLE XV.

SECTION 1. The right of citizens of the United States to vote shall not be denied or abridged by the United States or by any State on account of race, color, or previous condition of servitude.

SECTION 2. The Congress shall have power to enforce this article by appropriate legislation.

ARTICLE XVI

The Congress shall have power to lay and collect taxes on incomes, from whatever source derived, without apportionment among the several States, and without regard to any census or enumerations.

ARTICLE XVII

SECTION 1. The Senate of the United States shall be composed of two Senators from each State, elected by the people thereof, for six years, and each Senator shall have one vote. The Electors in each State shall have the qualifications requisite for Electors of the most numerous branch of the State Legislatures.

SECTION 2. When vacancies happen in the representation of any State in the Senate, the Executive authority of such State shall issue writs of election to fill such vacancies, provided that the Legislature of any State may empower the Executive thereof to make temporary appointments until the people fill the vacancies by election as the Legislature may direct.

SECTION 3. This amendment shall not be so construed as to affect the election or term of any Senator chosen before it becomes valid as part of the Constitution.

ARTICLE XVIII

SECTION 1. After one year from the ratification of this article the manufacture, sale, or transportation of intoxicating liquors within, the importation thereof into, or the exportation thereof from the United States and all territory subject to the jurisdiction thereof for beverage purposes is hereby prohibited.

SECTION 2. The Congress and the several States shall have concurrent power to enforce this article by appropriate legislation.

SECTION 3. This article shall be inoperative unless it shall have been ratified as an amendment to the Constitution by the legislatures of the several States, as provided in the Constitution, within seven years from the date of the submission hereof to the States by the Congress.

ARTICLE XIX

The right of citizens of the United States to vote shall not be denied or abridged by the United States or by any State on account of sex.

Congress shall have power to enforce this article by appropriate legislation.

ARTICLE XX

SECTION 1. The terms of the President and Vice-President shall end at noon on the twentieth day of January, and the terms of Senators and Representatives at noon on the third day of January, of the years in which such terms would have ended if this article had not been ratified; and the terms of their successors shall then begin.

SECTION 2. The Congress shall assemble at least once in every year, and such meeting shall begin at noon on the third day of January, unless they shall by law appoint a different day.

SECTION 3. If, at the time fixed for the beginning of the term of the President, the President-elect shall have died, the Vice-President-elect shall become President. If a President shall not have been chosen before the time fixed for the beginning of his term, or if the President-elect shall have failed to qualify, then the Vice-President-elect shall act as President until a President shall have qualified; and the Congress may by law provide for the case wherein neither a President-elect nor a Vice-President-elect shall have qualified, declaring who shall then act as President, or the manner in which one who is to act shall be selected, and such person shall act accordingly until a President or Vice-President shall have qualified.

SECTION 4. The Congress may by law provide for the case of the death of any of the persons from whom the House of Representatives may choose a President whenever the right of choice shall have devolved upon them, and for the case of the death of any of the persons from whom the Senate may choose a Vice-President whenever the right of choice shall have devolved upon them.

SECTION 5. Sections 1 and 2 shall take effect upon the fifteenth day of October following the ratification of this article.

SECTION 6. This article shall be inoperative unless it shall have been ratified as an amendment to the Constitution by the Legislatures of three-fourths of the several States within seven years from the date of its submission.

ARTICLE XXI

SECTION 1. The Eighteenth Amendment to the Constitution of the United States is hereby repealed.

SECTION 2. The transportation or importation into any State, Territory, or possession of the United States for delivery or use therein of intoxicating liquors, in violation of the laws thereof, is hereby prohibited.

SECTION 3. This article shall be inoperative unless it shall have been ratified as an amendment to the Constitution by conventions in the several States, as provided in the Constitution, within seven years from the date of the submission hereof to the States by the Congress.

CONSTITUTIONAL AMENDMENTS, History of. As shown in a preceding article (see CONSTITUTION, FRAMING OF THE), very few of the States liked the Constitution as a form of government at all, and fewer still were satisfied with it as an instrument. North Carolina had refused to ratify without amendments and a "bill of rights" affixed — a declaration of the fundamental rights of human beings to which immense importance was attached by the mass at that time; Massachusetts and New Hampshire ratified with an appended urgent recommendation of certain amendments; New

York first ratified subject to the right to secede if her amendments were not accepted within six years, and finally changed "on condition" to "in full confidence." The mass of amendments proposed in the first Congress was enormous; 103 from the States themselves, and 42 from minorities in other States, besides long bills of rights from New York and Virginia. Some of them were duplicates, but the total was very great; the House rejected them all and agreed on 17 articles in their place. The Senate cut them down to 12 and both Houses passed them; the first two failed of ratification by the States, the remaining 10 were accepted and went into force 15 Dec. 1791.

The text of the Amendments is to be found with the body of the Constitution.

The First Amendment (Article I) was violated by the government within a few years in the Sedition Act (see ALIEN AND SEDITION ACTS), and had no effect in accomplishing its defeat, which was effected by a party revolution. Nor has it prevented "gag laws," or exclusion from the mails of whatever has been thought obnoxious. Public opinion in these respects has been found more efficient than the Constitution.

General warrants were a principal grievance of the British customs laws, a fact which explains Article IV.

"Life *or limb*" in Article V is a curious anachronism; modern laws do not prescribe the rack as a punishment. Probably the drafters of this provision used a current phrase without stopping to analyze its meaning.

The provision of Article VI against changing the venue was doubtless suggested by the attempts to take Americans to England for trial.

The intrepid jumble of possible and impossible dangers of Articles VII–X, inclusive, reminiscences of 17th-century persecutions and 18th-century customs laws, of the times of King John and those of George III, of grievances unthinkable except under foreign rule and of others likely enough under their own, of local provisions and world-wide provisions, is amusingly characteristic of the period and the people; perhaps rather, any period and any people. The Amendments inspired the champions of a strong government with great weariness and disgust; but they are not all anachronisms or idle precautions. The Tenth especially (added by Massachusetts) has in practice restrained the action of the government greatly, especially in guiding the construction of the Supreme Court; and certain provisions of the Fifth, Sixth and Seventh have been great public safeguards, by no means out of date even yet.

See CHISHOLM V. GEORGIA, for the circumstances under which the Eleventh Amendment, put in force 8 Jan. 1798, was passed. Maryland had been sued by a private citizen, and submitted; Georgia was sued, refused to plead and threatened with death any one who served a writ in the suit; and she and Virginia pressed through an amendment forbidding such suits by individuals against States, but not vice-versa.

The gist of Article XII is the naming of the candidates for President and Vice-President separately; the lack of which provision brought about a discreditable intrigue, and results political and personal by no means forgotten. (See ELECTORAL SYSTEM; JEFFERSON-BURR IMBROGLIO). Before this, the highest candidate was President and the next highest Vice-President; but now came an election which showed not merely the possibility of a tie, but the certainty of one, between the two candidates of the same party from mere party loyalty. Yet plain as this seems, the Amendment failed in the first Congress where it was introduced, passed the House 12 Dec. 1803, only by the Speaker's casting vote, was ratified by the bare three-fourths of the States necessary, and declared in force 25 Sept. 1804. New Hampshire, Massachusetts, Connecticut and Delaware (Federalist States), rejected it.

The Emancipation Proclamation had freed only the slaves within the States technically in revolt. In those where the Union forces alone had prevented it, as Maryland, or a powerful minority of Union men plus resolute Union commanders, as Missouri, and generally in the Border States, the slaves were still private property, nearly 1,000,000 in number. Movements to compensate the owners were abortive, partly because the owners would not listen to such proposals; and the Thirteenth Amendment was introduced for entire emancipation without payment. Its phraseology is essentially that of the Ordinance of 1787 (q.v.), repeated in the Missouri Compromise and the Wilmot Proviso (q.v.). It passed the Senate April 1864, 38 to 6, and the House 15 June 95 to 66, but the latter was not the needed two-thirds. In the next session the House passed it, and it was ratified by 31 States, and proclaimed in force 18 Dec. 1865.

The Fourteenth Amendment, in part a rephrasing of the Fifth, arose out of the first Civil Rights Bills (q.v.), which was pronounced nonenforceable as contrary to the decision of the Supreme Court in the Dred Scott Case (q.v.), that negroes were not citizens. As this decision was law until distinctly reversed, the Amendment was drawn, the first clause clearing away that decision. The other sections were: (1) A bribe to the South to give the negro the vote; (2) to give the negroes a clear field by debarring the Confederate leaders from it; (3) obvious. It passed both houses in June 1866, by overwhelming votes, but a long struggle ensued over ratification. The old Confederate States rejected it, to which Congress retorted by the Reconstruction Act of 2 March 1867, constituting provisional governments in those States till they had ratified the Amendment, and they did so. Maryland, Delaware and Kentucky also rejected it; and New Jersey and Ohio were captured by the Democrats and rescinded their ratifications, though it was doubtful whether this could be done. But finally 33 States ratified without them, and the Amendment was declared in force 28 July 1868.

The Fifteenth Amendment was practically a substitute for the second section of the Fourteenth, which was found valueless. In one respect it was weaker than the other, which prescribed a penalty for the offense, while this prescribed none; but its specification of the negroes as the class not to be excluded, and their race or color or former slavery as not legal grounds for disfranchisement, gave it apparently a clearer legal footing. In fact, however, it has been found as little worth as the other. It passed both Houses in February 1869, by immense majorities, was ratified by 30

out of 37 States, and declared in force 30 March 1870. New York fell into the hands of the Democrats and rescinded its vote; a notice was filed in the State Department, which reported that the State «claimed» to have rescinded its ratification, but paid no further attention to it. It is more than doubtful if such action of a State has the least validity.

The Sixteenth (Income Tax) Amendment was passed by Congress and on 31 July 1909 was deposited in the office of the Secretary of State. On 3 Feb. 1913 it received one more than the required three-fourths of the votes of the States when Delaware and Wyoming voted to ratify the amendment, and on 25 Feb. 1913 it was declared in force. The purpose of the amendment was to obviate the necessity of distributing direct taxes among the States in accaccordance with their respective populations as provided in Section 3 of Article I of the Constitution. The Federal Income Tax Act of 1894 had been declared unconstitutional because it failed to provide for the apportionment according to representation in conformity with the Section of the Constitution referred to.

The Seventeenth Amendment, providing for the election of senators by the direct vote of the people, was introduced in Congress at the request of more than 30 State legislatures and in response to a popular demand that had resulted from 40 years of agitation. It was passed in the House 13 April 1912 and in the Senate 12 June, having already been ratified by the legislatures of three States — Massachusetts (22 May), Arizona (3 June) and Minnesota (10 June). On 9 May 1913 Wisconsin ratified the amendment, being the 36th State to take such action, and the amendment was declared in force 31 May 1913.

The Eighteenth (Prohibition) Amendment was ratified 16 Jan. 1919 and became effective 16 Jan. 1920. Only two States refused to ratify. See PROHIBITION.

The Nineteenth (Woman Suffrage) Amendment was ratified 18 Aug. 1920 and was proclaimed a part of the Constitution 26 Aug. 1920. See WOMAN SUFFRAGE. See also CONVENTIONS, CONSTITUTIONAL; INITIATIVE; REFERENDUM.

Ratification of the Amendments.— I to X inclusive were declared in force 15 Dec. 1791. XI was declared in force 8 Jan. 1798. XII, regulating elections, was ratified by all the States except Connecticut, Delaware, Massachusetts and New Hampshire, which rejected it. It was declared in force 28 Sept. 1804. XIII, the emancipation amendment, was ratified by 31 of the 36 States; rejected by Delaware and Kentucky, not acted on by Texas; conditionally ratified by Alabama and Mississippi. Proclaimed 18 Dec. 1865. XIV, reconstruction amendment, was ratified by 23 Northern States; rejected by Delaware, Kentucky, Maryland and 10 Southern States, and not acted on by California. The 10 Southern States subsequently ratified under pressure. Proclaimed 28 July 1868. XV, negro citizenship amendment, was not acted on by Tennessee, rejected by California, Delaware, Kentucky, Maryland, New Jersey and Oregon; ratified by the remaining 30 States. New York rescinded its ratification, 5 Jan. 1870. Proclaimed 30 March 1870. XVI, the income tax amendment, was ratified by all the States except Connecticut, Florida, Pennsylvania, Rhode Island, Utah and Virginia. It was declared in force 25 Feb. 1913. XVII, the amendment providing for the direct vote of United States Senators by the people, was ratified by all the States except Alabama, Delaware, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, Rhode Island, South Carolina, Utah and Virginia. It was declared in force 31 May 1913. XVIII, the prohibition amendment, was ratified by Mississippi 8 Jan. 1918. Fourteen States followed its example in 1918 and 30 States in 1919. Connecticut and Rhode Island did not ratify. XIX, the woman suffrage amendment, was ratified by 22 States in 1919 and by 15 States in 1920. Eight States ratified in regular session and 29 in special session. Nine States defeated ratification.

XX, so-called "Lame Duck" amendment, under which the terms of the President and Vice-President begin 20 January while Congress convenes and the terms of Senators and Representatives end on 3 January, was sponsored by Senator Norris of Nebraska, approved by Congress 2 March 1932, and submitted to the legislatures of the several States for ratification. By 23 Jan. 1933, it had been ratified by 36 States and on 6 Feb. 1933, it was proclaimed a part of the Constitution, to become effective 15 Oct. 1933, by which time all States had ratified.

XXI, the Prohibition Repeal amendment, was finally approved by Congress, 20 Feb. 1933 and on the following day was submitted to the States for ratification by conventions. By 5 Dec. 1933, 36 States had ratified it and it immediately went into effect. It is the only amendment to the Constitution to be ratified by the convention system.

CONSTITUTIONAL CONVENTIONS. See CONVENTIONS, CONSTITUTIONAL.

CONSTITUTIONAL LAW. See LAW, CONSTITUTIONAL.

CONSTITUTIONAL UNION PARTY, in United States history, popularly known in its own time as the Bell-Everett party, from the names of its presidential candidates; the name assumed by the remnant of the Southern Whigs in 1860. The platform consisted of a preamble antagonizing all platforms in general as local, and a resolution recognizing as the only right and duty of every citizen the support of «no political principle other than the Constitution of the country, the Union of the States and the enforcement of the laws.» The leaders invited members of both parties to unite in forming a program ignoring the slavery issue altogether. In the election of 1860 it carried Kentucky, Tennessee and Virginia, and had a total popular vote of 589,581 and a total electoral vote of 39. After this campaign, the party was submerged in the Civil War and went out of existence.

CONSTITUTIONS, Fundamental. See COLONIAL GOVERNMENT, PROPRIETARY.

CONSTITUTIONS, State. See UNITED STATES—THE FORMATION OF STATE CONSTITUTIONS; UNITED STATES—FORMATION OF STATE CONSTITUTIONS; CONVENTIONS, CONSTITUTIONAL.

CONSUBSTANTIATION, the doctrine that in the Holy Eucharist the real body and blood of Christ are present and are of the same substance with the bread and wine. The doctrine of Transubstantiation is that when the words of consecration are pronounced by the priest, the bread and wine are substantially changed into the body and blood of Christ, and

consequently cease to exist as bread and wine. The doctrine of Consubstantiation, on the contrary, is that after consecration they continue to exist in their original form, but substantially conjoined with the body and blood of Christ.

This doctrine, generally ascribed to John of Paris, as its earliest advocate, has had few, if any, confessors. The term «Consubstantiation» is often incorrectly used to designate Luther's doctrine of the sacramental conjunction with the bread and wine, which is a very different thing from that of the substantial conjunction. See LUTHERANISM.

CONSUELO, which appeared from the hand of George Sand in 1842–43, a fantastic tale with a number of genuinely historical characters, reflects the innumerable theories of social reform and the mystical, quasi-philosophical ideas then in the air. George Sand was at that time under the influence of the religious radical Lamennais, of the humanitarian revolutionary Pierre Leroux, of the Polish musician Chopin, of the Polish poet Mickiewicz and his Slavic mysticism. The action of *Consuelo* is placed in the middle of the 18th century. The heroine, a wonderful Venetian singer, is a fanciful portrait of the author's friend, the singer Pauline Viardot. The character is made to embody the ideas of the Saint-Simonian socialists, of Liszt and of Lamennais, as to the sacerdotal rôle of great musical artists. She is the pupil of the noted composer and singing-master Porpora. Eluding a selfish and unworthy lover, she escapes and enters the castle of the noble family of Rudolstadt in Bohemia as music-teacher. The heir of the family, Count Albert, loves her. He is a strange being, living a mysterious life, who speaks and acts as though he reincarnated previous human existences. Here is again seen the influence on the author of Leroux and his theories of the immortality of man in humanity. Consuelo, not sure of her own love, escapes again and wanders through the world disguised as a boy with the young musician Haydn. At the court of Maria Theresa in Vienna she rises to fame in spite of the jealousy of her former lover's mistress, Corilla. But she is recalled to Rudolstadt by the illness of Count Albert whom she marries on his death bed, thus symbolizing the democracy of art and humanity and the union of classes. The later history of Consuelo is continued at equal length in the sequel, *La Comtesse de Rudolstadt. Consuelo* seems today old-fashioned and long-winded, but it embodied the genius of its author and the aspirations of an age of reformers whose ideas were yet nebulous and impractical.

CHARLES H. C. WRIGHT,
Professor Emeritus of French Language and Literature, Harvard University.

CONSUL, the title given to the two chief magistrates of the ancient Roman Republic and to the three supreme magistrates of the first French Republic during the last five years of its existence. In present usage the term indicates an official who resides in a foreign seaport or other commercial center as the representative of his home government and who is charged with the protection of his fellow-countrymen and the safeguarding of their interests.

The office of consul was created in Rome about 508 B.C., after the expulsion of the kings. The election to the consulship was annual, and only patricians were eligible until the Licinian laws opened the office to the plebeians.

In the history of France the title of consul appears after the fall of the Directory, when three consuls were appointed. The constitution of 13 Dec. 1799 gave to the first of these magistrates the real power, the others having only an advisory voice in the government. Napoleon Bonaparte became First Consul. In 1802 he was confirmed in the consulship for life, and in 1804 he abolished it by the establishment of the Empire. The office of consul in the present signification of the term had its origin in the extensive trade relations of the Italian cities of the 12th century.

In United States law and common parlance, it is a generic term denoting a civil official exercising the functions of a consul general, consul, or vice consul. Ordinarily he resides in a seaport or important commercial center. His fundamental duties are, in his limited district, to represent the power appointing him and to protect its interests and nationals. He inherits a tradition of duties dating back two and a half millennia or more.

A Greek consul today in his native tongue is called *proxenos*. His prototype of the 8th century B.C. was called a *suffete* by the Phoenicians or Carthaginians and a *proxenos* by the Athenians (in Athens, Demosthenes was *Proxenos* for Thebes). He was the highest resident representative of the city state by which designated, and judge in the disputes of its citizens as well as their protector. Such officers may have owed their origin to the necessities of commerce between states, as held by most authorities, or to the noble humanitarian instincts of hospitality and charity as argued by Alberto Candioti; normally in those times the stranger was an enemy and driven away or enslaved. It was the primary duty of a *proxenos* to entertain foreigners from the community he represented if distinguished and to succor them if unfortunate. Seamen or those otherwise connected with commerce were his special charge. In some cases he was punished like a hostage for the acts of those he stood for. He was subject to local municipal law.

When the independent Greek states were conquered by Rome, the *proxenial* institution was followed by that of the Roman *patronatus*, who derived office in a different way but exercised similar functions. This in turn was succeeded by the *consulate* of the Middle Ages.

A medieval consul combined many of the functions of a modern ambassador, consul general and ex-territorial judge. In the port or district of his residence he represented the government of another land, protected its shipping and commerce and the property and persons of its citizens, and settled quarrels of its nationals according to its law.

These traditional consular duties were exemplified until a few years ago in the powers of an American consul general in China, Turkey, or Morocco.

The consuls' institutional line of succession has been followed. That of his title will now be traced. Those called consuls in ancient Rome were the two elected rulers and principal magistrates. After the expulsion of Tarquin in 510 B.C. the two were chosen each year by the Plebians and the Patricians. At home the Roman consul was a chief of state. In a for-

eign land he was the ranking representative of the republic and his powers were limited only by his likes and his legions. The pithiest and most publicised of consular reports was by the greatest of consuls. In August 47 B.C. according to Suetonius, after a most successful campaign of some eight months with Cleopatra in Egypt, and about eight weeks against the son of Mithridates in Pontus, Consul Julius Caesar reported to Amantius, *Veni, vidi, vici* («I came, I saw, I conquered»). When he entered Rome with a «triumph» the following summer those three words were inscribed on his banners.

During the reign of Caesar's heir and grandnephew, Emperor Augustus, and throughout the empire consuls continued to be elected, but their responsibilities became less administrative and more those of presiding magistrates of the judiciary. Finally they were figureheads. After the 5th century A.D. the name of consul as a badge of honor was borne by emperors at Rome and Byzantium, by kings and princes of trading lands in the west of Europe, by governors of city states in Italy, Spain and France, and by many counts, lords and, magistrates in control of navigation and commerce.

In the Middle Ages consular titles varied. That of *Consul à l' Etranger* is held to have originated during the First Crusade, when a representative of the Republic of Genoa was so recognized at Antioch in 1098 by Bohemund I in gratitude for military aid received. Others ranged from *Consul des Marchands, Consul de Mer* or *Consul de Navire* to consul. The title came in for a flare of renown from 1799 to 1804 when it was briefly carried by Napoleon as First Consul, and by Lucien Bonaparte and Abbé Sieyès, writer of constitutions, as consuls of the first French Republic.

At present the general acceptation of the term may best be understood by examining the status of foreign consuls as officially recognized in the United States, which is typical and standard for modern times. In 1944 all 20 of the Latin American republics and 33 other countries had representatives of consular standing in the continental United States; Mexico 91 and Great Britain 76. Altogether there were 1,012, of whom 497 were honorary. In no other country are they more numerous or treated with more scrupulous respect for international law and comity.

Consuls must have commissions from their governments and must be recognized by the American State Department before they undertake official activities. These cover notarial services, commercial invoices, ship's manifests, crew lists, seamen's relief, and shipping in general; visas for Americans and foreigners visiting their countries; passports, registrations, and records of marriages, births, deaths, and estates of the represented nationals; mediation in behalf of individuals and national organizations; counseling travelers and introducing distinguished visitors from the homeland; and a wide variety of duties as observers of laws and possible discrimination and as economic and commercial reporters. Unofficially they are often the arbiters of disputes.

Consuls are in all the principal cities and are basically subject to local law and civil suit like any other citizen or resident. By international comity and treaty, however, those of career enjoy certain advantages such as inviolability of person, dwelling, and official papers; exemption from jury and military service and billeting; and from direct taxation, import duties, and excise taxes when provided for by treaty or reciprocal agreement. They normally, except in cases of crime, enjoy freedom from search warrant and arrest. In the District of Columbia there are no property taxes on their automobiles. Special protection is given them in the discharge of their official responsibilities.

Oddly enough, almost none of the authorities writing on the consular institution have observed the closeness of the parallel between the ancient *proxenos* and the present honorary consul. Merely the chief similarities need be noted here: citizenship ordinarily of place of residence and not of the appointing power, political tenure, lack of pension benefits, remuneration from private business or fees rather than fixed pay, promotion, and allowances; full amenability to local law like an ordinary citizen—although social and other advantages accrue to him, as well as his career colleague, out of established local custom. The career consul, on the other hand, who became known as such in 1588 under the great French administrator Jean Baptiste Colbert (q.v.), has secure status, pay, promotion, and retirement prospects like a professional army or navy officer, besides superior privileges and exemptions based on treaty and international law. Further details about American consuls may be found under FOREIGN SERVICE OF THE UNITED STATES.

CONSUMERS' LEAGUE. See NATIONAL CONSUMERS' LEAGUE.

CONSUMPTION. There have been two meanings given by economists to the term consumption of wealth. By one group it has been made to include any utilization of wealth in which the wealth is used up or destroyed in the process. By another group it means only such utilization as gives direct satisfaction to a consumer. Under the first definition, coal is consumed when it is burned to make steam for the running of machinery as well as when it is burned to supply warmth for the comfort of the human body. Under the second definition only the latter use of coal would be called consumption. They who hold to the first definition are compelled to divide consumption into two kinds, namely, productive consumption and unproductive consumption. It is always explained, however, that the term unproductive consumption does not mean useless or unnecessary consumption. It means merely that wealth thus consumed, in contradistinction to that which is productively consumed, is not used up in the process of producing other wealth.

By the consumption of wealth in the narrowest sense is meant the culmination of the whole economic process, namely, the satisfac-

tion of human desires. Wealth which is used up or worn out in the process of production is not itself yielding consumers' satisfactions directly. It is helping to produce other things which will directly satisfy consumers and may therefore be said to be indirectly satisfying desires. By the consumption of wealth, under this narrower definition, is meant its utilization in the direct satisfaction of human desires. The physician's automobile which is used in his profession is being worn out, but it is not being consumed in the technical economic sense. But when it is used for his own enjoyment or that of his family it is being consumed. Again, a thing may be in the process of consumption even though it is being used up very slowly. A diamond which is used as an article of pleasure or adornment is in the process of consumption even though it may never be really worn out. A substantial piece of furniture, when used for direct satisfaction, is being consumed. While it is in a furniture store, the immediate purpose of the owner is to gain a profit from it rather than to enjoy it. Therefore it is not yet in the process of consumption. In short, the consumer of an article is the one whose desires it satisfies directly. The article begins being consumed whenever it begins satisfying a consumer's desires directly, that is, when it has passed through all the channels of business and trade, where it was used for the purpose of getting an income, and passes into the possession of someone for whose satisfaction it was designed.

Most textbook writers on economics have regarded the consumption of wealth as a department of the subject, co-ordinate with such departments as production, exchange and distribution. None of them, however, has given as much space to it as to these other departments. The reason apparently has been the general opinion that consumption is essentially an individual matter with which the public has had little or no concern. Laws relating to consumption have been called sumptuary laws, and have generally been condemned, or only half-heartedly approved. There is a growing opinion, however, that consumption is quite as important, from its effects on national prosperity, power and greatness, as any department of economics. Even the regulation of consumption, as in the case of laws regulating or prohibiting the use of habit-forming drugs has secured unanimous popular assent. The prohibition movement, on the other hand, has evoked the bitterest controversy.

The importance of the consumption of wealth is further emphasized by the consideration that as many and as dire calamities have overtaken nations and peoples because of their irrational habits of consumption as because of inefficient systems of production, exchange or distribution. In fact, there is a very profound reaction of consumption upon all the other departments, particularly upon distribution. The standard of living of the laboring classes, which is a part of consumption, has much the same influence upon the price of their labor as that exercised by the cost of production upon the price of a material commodity. Again, the rate of the accumulation of capital, upon which so many things depend, is largely determined by the habits of consumption. The effect of luxury upon industry and general national strength is one of the largest of all questions. These illustrations are enough to show that the subject of consumption deserves the most careful study and the most serious treatment which economists can give it. Systematic work on the principles of consumption has been done by Cuhel, 'Zur Lehre von den Bedürfnissen' (Innsbruck 1907), and Brentano, 'Versuch einer Theorie der Bedürfnisse' (Munich 1908). Examples of the application of the principles of consumption to the problems of progress are found in Wyand, C. S., 'Economics of Consumption' (New York 1937); Bigelow, H. F., 'Family Finance' (New York 1936); Hutt, W. H., 'Economists and the Public' (London 1936). See DISTRIBUTION; INCOME; WEALTH.

Harvard University.

CONSUMPTION. See TUBERCULOSIS.

CONTACT, in astronomy, a word used in describing eclipses of the sun and moon, and also the transits of the inferior planets. In a solar eclipse contact takes place at the instant when the limbs of the sun and moon just touch each other either exteriorly or interiorly; in a lunar eclipse, when the shadow of the earth just touches the limb of the moon; and in the case of a transit of Venus or Mercury, when the limb of the planet just touches the sun's limb either exteriorly or interiorly. The instant of interior contact and of exterior contact are distinguished by these names.

CONTACT ACTION. See CATALYSIS.

CONTACT METAMORPHISM. See METAMORPHISM.

CONTAGION. Before the time when the microscope and other laboratory aids showed the actual causes of many disease processes in the human — and other animals — body, the word contagion was surrounded by much mystery. At the present time the term «communicable» is preferable. Thus communicable diseases are those which result from actual or remote contact with the host. There are a great many such communicable diseases. The actual contagium or causative factor is known for many, while for others it has yet to be definitely determined. In many instances where the actual contagium is known, the method of the transmission is still in doubt. Thus in the group of exanthematous diseases such as measles, scarlet fever, smallpox, chickenpox, the actual contagion has not been demonstrated. For diphtheria, whooping cough, boils, carbuncles, tuberculosis, typhoid fever, cerebrospinal meningitis, gonorrhea, plague, cholera, pneumonia, erysipelas and influenza the actual causative agents are minute plants belonging to the group of bacteria. The contagium of syphilis, sleeping sickness, yaws, Aleppo boil and a group of related diseases are minute animalculæ of the protozoa group. The contacts here are direct; while malaria, which is also a communicable disease, is caused by a minute animal form of the protozoa group, which is usually transmitted by an intermediary host, such as the mosquito. Thus in malaria the process is as follows: The minute animal form causing it is found in the blood and other tissues of the sick individual. This is taken into the body of a biting mosquito, usually of a special type, Anopheles; for the common chills and fever of the United States, the malarial parasite undergoes a series of

changes in its mosquito host and then is carried to a well individual through the bite of an infected mosquito. In former years much nonsense was talked and taught by physicians about miasmas, and dangerous night air, and the harmfulness of dampness, etc. The dangers existed, not in a hypothetical miasm, but in real mosquitoes that usually flew and fed about dusk and which lived in wet, springy localities If there were no patients with the parasite, there would be no malarial plasmodia to be communicated. Hence malaria is stamped out either by getting rid of mosquitoes or isolating patients and preventing the mosquitoes from carrying away blood with the real cause.

Many communicable diseases are borne by the air and involve the respiratory tract. Influenza and pneumonia are among these. In epidemics breathing masks worn by the sick may prevent spread of contagions. Typhoid fever and cholera are usually communicated by means of the digestive canal. They are best eradicated by proper sanitation. They are preventable. A community which has much typhoid fever is deficient in social intelligence. Such a community prefers corrupt politics to clean water supplies and deserves what it gets, the death of its young people. High percentages of typhoid in communities is in direct proportion to the social enlightenment of the same communities.

In general it may be said that so-called disinfectants, etc., which are used to prevent communicable diseases are a relic of the dark ages. «Cleanliness is next to godliness» is a good maxim, but should apply to spiritual cleanliness as well. The fight against gonorrhea and syphilis is a losing one. The moral tone of the race is still too infantile to stamp these scourges out in the community as yet. Certain restrictive measures are of some service, but a higher degree of sexual intelligence is needed to combat these two prevalent communicable diseases. So long as knowledge of the most important function of the human race is considered improper, so long will gonorrhea and syphilis be widespread. When the community realizes that sex knowledge is the most important kind of knowledge to have, then that community will gain the ascendancy over the so-called venereal diseases, and those individuals who have grown away from their infantile sexuality will live.

There is a whole group of communicable diseases due to contagions from animals. Such are tape worm, hook worm, round worms, etc. Here the ova, or eggs, pass from the animal direct, through handling dirty animals, dogs particularly, or the fecal matter containing the ova is conveyed through water supplies, or through food contaminated by infected water. The old distinctions between contagion and infection are no longer tenable, hence the terms are used interchangeably, or better, supplanted by the term communicable.

SMITH ELY JELLIFFE.

CONTARINI, kōn-tä-rē'nē, the name of a noble family of Venice, one of the 12 that elected the first doge. The most important members were DOMENICO, doge of Venice from 1043 to 1071 or 1073. He rebuilt Grado, and reduced the city of Zara, which had revolted. During his reign the rebuilding of Saint Mark's Church was undertaken. JACOPO, doge from 1075 to 1080. Under his reign the Venetians forced the city of Ancona to acknowledge their sovereignty over the Adriatic Sea. ANDREA, doge from 1367 to 1382. The Genoese, under Pietro Doria, had conquered Chiozza in 1379, and threatened even Venice. Andrea Contarini reconquered Chiozza, captured the Genoese fleet and delivered the republic from its enemies (1380). FRANCESCO, frän-chĕs'kō, doge from 1623 to 1625. Under him Venice, in alliance with Louis XIII of France, the Duke of Savoy and the Protestant cantons of Switzerland, reconquered the Pays de Vaud in 1624, of which the Austrians had taken possession. CARLO, doge from 1655 to 1656. Under his reign Lazaro Mocenigo, admiral of the republic, in June 1655 gained a brilliant victory over the Turks in the Dardanelles. DOMENICO, doge from 1659 to 1674. During his government Venice resisted for five years the attacks of the Turks on the island of Candia; but on 26 Sept. 1667, after a siege and defense of unexampled obstinacy, Francesco Morosini surrendered the island. AMBROGIO, äm-brō'jō, from 1473 to 1477, was ambassador of the Republic at the court of the King of Persia, Usun Kassan. The interesting description of his residence at this court first appeared at Venice in 1487, in Italian. GASPARO, diplomatist, who served as Venetian Ambassador to the Diet of Worms in 1521. From there he accompanied Charles V to the Netherlands, England and Spain and negotiated a permanent peace between the Republic and Charles V in 1529. Pope Paul III conferred on him the cardinal's hat in 1535. In 1541 he was papal legate at the Diet of Ratisbon, where he distinguished himself by his moderation. After his return he was sent as legate to Bologna, where he died in 1542. GIOVANNI: b. Venice 1549; d. 1605; was one of the most distinguished painters of his age. He worked in the style of Titian, and was particularly skilful in painting ceilings; for example, his 'Resurrection' in the church of San Francesco di Paolo, in Venice. VINCENZO, vēn-chĕn'zō: b. Venice 1577; d. 1617; a scholar whose reputation was in early life so great that the magistrates of Padua established a new chair of Latin and Greek eloquence only to retain the learned youth of 26 years of age in their city. He lectured there until 1614. At one time there were no less than 18 branches of the family; one of the most important was that of Contarini dallo Zaffo or di Giaffa who had been invested with the countship of Jaffa in Syria for their services to Caterina Cornaro, queen of Cyprus; another was that of Contarini degli Scrigni, so called on account of their great wealth.

CONTÉ, kôn-tā', **Nicolas Jacques,** French inventor: b. Annon-sur-Orne, near Sées, 4 Aug. 1755; d. Paris, 6 Dec. 1805. He was at first a painter but afterward turned to the mechanical arts and when France was deprived through its war with England of its plumbago supply, he invented a substitute in the shape of a mixture of graphite and clay which was subsequently used for the manufacture of black lead pencils, known as «crayons Conté.» This process was the foundation of all subsequent manufactures of pencils. After several successful experiments in the use of the balloon

for military purposes he was made director of the French Aërostatic Institute and chief of the aërostatic corps of the army. He accompanied the French army at the time of Napoleon's expedition to Egypt and erected works in Cairo for the manufacture of arms, ammunition, surgical instruments, bread and other necessaries. He also invented a barometer (1798) similar to Vidi's. In 1802 he instigated the foundation of the Society for the Encouragement of National Industry. When the results of the Egyptian expedition were ready to be published, Conté was commissioned to take complete charge of its production. He endeavored to construct an engraving machine for this purpose, but died before the work was well under way. Consult Jomard, 'Conté, sa vie et ses travaux' (Paris 1852).

CONTEMPORANEITY OF GEOLOGICAL STRATA. Formerly strata found partly with identical, partly with allied fossils, were held to be exactly contemporary, though widely separated on the earth's surface; now the same facts are used to establish the contrary conclusion. If each species came into existence at a certain spot on the earth's surface, from which it gradually spread in various directions, it cannot have reached a remote region till some considerable time after its birth. Two strata, then, widely separated in the world, containing some species common to both, are contemporaneous in this sense, that they were formed while that species lived; but the stratum near its birthplace is likely to be older than the one to which it spread after it had already multiplied greatly and rooted itself successively in all of the intervening regions, wherever a place appropriate for its habitation could be found.

CONTEMPT, a wilful disregard or disobedience of a public authority. The Constitution of the United States provides that each House of Congress may determine the rules of its proceedings, punish its members for disorderly behavior, and, with the concurrence of two-thirds, expel a member. The same provision is substantially contained in the constitutions of the several States. The power of making rules carries with it that of enforcing them, and the power to attach persons who violate them, and to punish them for contempt. Courts of justice have an inherent power to punish all persons for contempt of their rules and orders, for disobedience of their process and for disturbing them in their proceedings. The penalty is fine or imprisonment or both. The guilty person may have these penalties remitted by "purging" the contempt, i.e., by making pecuniary reparation for any damage resultant of his action, and by apologizing for his fault. The breach of the rules of conduct set down by the judiciary for certain persons, though committed out of court, is a contempt, also. The use of this jurisdiction of punishment for contempt in labor disputes has been given the name of "government by injunction" as an arbitrary method of dealing with offenses without trial by jury and the other safeguards of criminal law. Consult Rapajje, 'Treatise on Contempt' (New York 1884); and Oswald, 'Contempt of Court, Committal and Attachment and Arrest on Civil Process' (London 1895).

CONTES BLEUS, kônt' blē' (Blue Tales). The 'Contes bleus' of Edouard Laboulaye are stories, mainly fairy tales, from various sources, including the invention of the author, which owe their charm not merely to the material of folk-lore that they contain and to the stamp of the popular imagination that it bears, but also and in larger measure to the alert, graceful and good-humored style in which they are told. For Laboulaye was really very far from the naïve popular imagination in which fairy tales were born, and even in retelling authentic ones he slips in many a mischievous thrust at the weaknesses of poor human nature, many a satirical reflection on social and political institutions, and often comes dangerously near pointing a moral. Indeed he distinctly recommends the reading of fairy tales for children for their moral value. "There is often more moral stuff in a fairy tale," he says, "than in all the history of Rome. They were born of the wisdom of the race." In proportion as he draws more on his own invention, the marvelous becomes the transparent mask of whimsical satire directed against the vices and foibles of men and informed by the love of free and liberal institutions of which Laboulaye was an ardent defender. By the nimbleness of the mind that plays about the most various themes and touches grave questions with a laugh, by the sparkling wit and the mordant irony, some of these tales might almost be taken for "contes philosophiques" of Voltaire — of a lesser, good-humored Voltaire, without the sneer.

The 'Contes bleus' appeared in three volumes: 'Contes bleus' (1863); 'Nouveaux contes bleus' (1867); 'Derniers contes bleus' (1883). They have been in part translated by Mary L. Booth under the title Laboulaye's 'Fairy Book' (New York 1866).

ARTHUR G. CANFIELD,
Professor of Romance Languages, University of Michigan.

CONTES D'HOFFMANN, Les, opera by Offenbach (q.v.), first produced in Paris 10 Feb. 1881: in New York, 14 Nov. 1907.

CONTES DE FÉES, kônt' dė fā' (Fairy Tales). The 'Contes de Fées,' or Fairy Tales, published in 1697 under the name of "Perrault Fils," who was then only 10 years old, were written by his father, the Academician Charles Perrault, better known through his controversy with Boileau about the relative merits of the Ancients and Moderns. The stories were not original, but belonged to the universal folk-lore, as old as humanity itself; to Perrault belongs the credit of having given to them a definite literary form, not entirely free from certain mannerisms of the time, yet simple, natural and well adapted to the subject and to the minds of children. Such stories as 'Blue Beard,' 'Puss in Boots,' and 'The Sleeping Beauty' have become a part of the world literature of childhood, and have been widely imitated everywhere.

Published under the title 'Contes de ma mère l'Oye,' or Stories from Mother Goose, both stories and title have caused many speculations as to their origin. The most plausible theory about the origin of such stories is that the human mind in its infancy received the same impressions from the various phenomena

of nature, and from its own feelings of hunger, fear, love, etc. The stories telling of such emotions were further modified by migrations to different countries and climes. 'Mother Goose' has been said to represent many noted personalities, from the wife of Charlemagne to the Queen of Sheba, and even the Virgin Mary! She is more likely the personification of the "Grandmother" or the "Old Nurse" giving free rein to her imagination for the entertainment of young children. The "Fairies" who do such wonderful things in these stories are, as their name indicates (French: *fée;* Latin: *fatum, fata,* fate, destiny), the living representation of the many influences which affect our lives, favorably or otherwise. They are creations of the mind instinctively attracted and affected by the unusual, the mysterious and the unknown.

Perrault's 'Fairy Tales' have been translated into all languages; they have brought about the collection of many stories of folk-lore in all countries, and have been widely imitated, particularly by the Brothers Grimm, Hans Andersen, etc., and in France by George Sand, 'Stories of a Grand Mother'; Ch. Nodier, 'Evening Stories'; and Daudet, etc.

LOUIS A. LOISEAUX.

CONTESTED ELECTIONS. See ELECTIONS.

CONTI, kôn'tē', the name of a distinguished French family, a younger branch of the Bourbon house of Condé, deriving its title from the small town of Conti near Amiens. It sprang from Armand de Bourbon, Prince of Conti, brother of the great Condé (b. 1629; d. 1666). He took an active part in the troubles of the Fronde both for and against the court, and married the niece of Mazarin. His son, François Louis (b. 1664; d. 1709) was brought up under the eyes of the great Condé, served with distinction under the Duke of Luxembourg, and was elected king of Poland by a number of the magnates, but declined the honor. The last of the house of Conti was Louis François Joseph, b. 1734; d. 1814.

CONTI, Augusto, Italian philosophical writer: b. San Miniato, Tuscany, 1822; d. 1905. He studied law at several Italian universities and practised in Florence until 1848, when he enlisted as a volunteer for service against Austria. Subsequently he practised law and taught philosophy at San Miniato, in 1855 was made professor of philosophy in Lucca, in 1863 professor of the history of philosophy in Pisa, and in 1864 professor of mental and moral philosophy in Florence. His published works include 'Evidenza, amore e fede, o i criteri della filosofia' (1862, and subsequent editions); 'Storia della filosofia' (1864); 'L'Armonia delle cose' (2 vols., 1878); 'Filosofia elementare' (1869; 9th ed., 1879); 'Dio come ordinatore del mondo' (1871); 'Il vero nell' ordine' (1876, 1891). In these works Conti makes an earnest attempt to bring into agreement the teachings of different philosophical schools.

CONTINENT. A definition of continent based on the origin and development of land masses is not possible in the present state of our knowledge, and about all that can be done is to define a continent as a very large body of land. Africa, North America, South America, Europe, Asia and Australia are such land areas, but since Europe and Asia form a single land mass, many physical geographers speak of the two as one continent — Eurasia. There is also probably a land area of continental size in the Antarctic regions.

Origin of Continents.— The solid earth, the lithosphere, is largely covered by water, the hydrosphere; the proportion of land to water on the surface of the globe being about 1 to 2.63, making the land surface about 27.5 per cent of the total. The extreme height of the land above sea-level is about five miles (Mount Everest 29,000 feet), and the extreme depth of the ocean somewhat more; the extreme relief of the lithosphere is therefore over 10 miles. According to Lapparent the mean elevation of the continents is as follows: Europe 958 feet; Australia 1,118 feet; South America 1,702 feet; North America, 1,953 feet; Africa 2,007 feet; Asia 2,883 feet. The mean height of all land is estimated at a little over 2,000 feet, and the mean depth of the ocean at 12,000 to 15,000 feet. Therefore if the solid earth, the lithosphere, were free from inequalities, the hydrosphere would cover it, perhaps to a depth of over two miles. Inequalities of surface have, however, existed since the earliest geological time of which we have knowledge. The oldest rock formations show traces of sedimentary origin, and therefore represent in part the waste of land areas from the action of streams and the waves of the ocean. So far as North America is concerned the position of the continent had been determined in Archæan time. What determined the position of this and other continents is, however, still an unsolved problem, though there are several theories, each with some show of reasonableness.

The generally accepted theory is that when the crust of the molten earth had solidified and cooled enough to allow the condensation of aqueous vapor, it cooled and contracted unequally, some parts cooling and contracting toward the centre more rapidly than others. Thus were formed areas of depression and elevation, the seas filling the former, and the higher parts of the latter projecting above the water as land. The water would hasten cooling under the depressions, and thus the general tendency would be to increase the area and elevation of the land and increase the depth, but decrease the area of the sea. Those who hold that the earth was never molten believe that the oceanic segments are heavier than the continental (a fact substantiated by actual investigation), and that as a result, the continental blocks are forced aside and up by the settling of the heavier oceanic blocks.

Distribution and Form of Continents.— The distribution and form of continents show some curious features, and on these features theories of the origin of continents have been based. North and South America, for instance, are roughly triangular in shape, with the apex of the triangle at the south. Eurasia and Africa together form another roughly triangular land area tapering to the south, the Cape of Good Hope being the apex of the triangle. Owing to the lands tapering to the south, the northern hemisphere contains more land than the southern, and it is possible to divide the globe, by taking a north pole in the English channel, into

two hemispheres, one nearly all land, and the other nearly all water.

Continents consist typically of a great interior basin bordered by mountain ranges, this form being shown by the continents of somewhat regular outline, the irregular Eurasian continent being an exception. In each continent the greatest mountain system faces the greatest ocean. In North and South America these mountains are on the west, facing the Pacific, with the smaller Appalachian Mountains, the Venezuelan Mountains and Brazilian highlands facing the Atlantic. In Africa the greatest range is on the east, facing the Indian Ocean, in Australia the greatest range faces the Pacific, and in Asia the Himalayas face the Indian Ocean. Omitting the mountains of Eurasia, the mountain chains of the world have a northwest-southeast or northeast-southwest direction, and on this account the continents taper toward the south.

From the base of the mountains to the sea is a gentle slope or plain, and this plain extends frequently some distance beyond the shore, forming a continental platform or shelf. The outer edge of this platform is usually at a depth of about 100 fathoms (600 feet) when the bottom slopes rather sharply — forming the continental slope — to the depths of the ocean. Off the coast of New Jersey the 100-fathom line is 110 miles from shore, while on the coast of California it is only about 10 miles from shore. Great Britain stands on such a shelf and is really part of the continent of Europe. In the same way the East India islands to Celebes are part of Asia. New Zealand may be considered part of Australia.

Permanency of Continents.— It is one of the commonplaces of geology that the lands are continually changing; by weathering, by rivers and by the waves of the ocean the rocks are worn away and spread out as sediments on the sea floor. In some parts of the world the land is apparently rising, in others sinking. The northern coast of Norway is rising five feet in 100 years, the coast of New Jersey and parts of the New England coast are sinking. At Boston the rate is about one foot in 100 years, and on the New Jersey coast two feet. Yet geologists, while admitting the instability of the lands, differ as to the permanency of continents. Lyell believed that neither continents nor oceans — so far as any particular part of the earth is concerned — are permanent. His views have been opposed by later geologists, who have thought that while continents may change form, certain parts of the earth have always been covered by oceans, while others have not; the Atlantic and Pacific, for instance, were always oceans, while the continents, even if at times partly covered with water, have always been uplifts in the sea floor, or if not always, at least since Archæan times.

It is recognized, of course, that these uplifts have been under shallow, or epicontinental, seas many times. This is shown by the following facts. In the first place, chalk beds corresponding to the globigerine ooze that covers much of the ocean floor are found in the interior of continents; in the second place, the study of fossils has shown that at times in past ages continents now separated by oceans had essentially the same fauna and flora. The evidence of deep-sea deposits shows that in Cretaceous time a fairly deep sea covered much of Mexico and parts of Texas, New Mexico, Arkansas and Kansas, while another, or perhaps the same wide, deep sea covered southern Europe and northern Africa and extended across Asia to the Pacific. In Cretaceous time, therefore, the continental land masses did not have their present form and arrangement, and theories as to the origin of continents based upon present land forms are at best of doubtful value. The evidence of fossils indicates that in Permian time the Antarctic land mass was of far greater extent than now, and joined South Africa, Patagonia and Australia. Again in Cretaceous time the evidence indicates that Brazil, south central Africa, Madagascar and India were connected by land masses, so that the Atlantic and Indian oceans had not at all their present shape. There is some reason for believing that no longer ago than the beginning of the Glacial Period the Arctic lands were of far greater extent than now, Asia, North America and Europe being connected. Thus, while it is fair to assume that the position of the continents was determined ages ago, there is nothing permanent about their forms or the present distribution of land and water on the earth. CONTINENTAL NAVY. During the summer and fall of 1775, the British attempts to subdue resistance in the colonies on land was supplemented by harrying their shipping and coasts by sea. Several merchant vessels were made prizes in violation of law. Gloucester was fired on, and Bristol bombarded to obtain provisions. Most of the colonies equipped armed vessels for themselves and commissioned privateers. On 5 October news came that two British transports were on the way to Quebec with military stores; and as our armies needed these worse than the British, Congress on the 13th appointed a board of three (Silas Deane, John Adams — afterward replaced by Christopher Gadsden — and John Langdon) to fit out two swift armed vessels and intercept these or any other store-ships. This board was the Navy Department of the Revolution for a time; it was turned into a marine committee, marine board, etc., with under boards called the Continental Naval Board, Board of Admiralty, etc. On 18 October Falmouth (now Portland) was bombarded and set on fire; and on the 30th two more and heavier vessels were authorized. The naval committee was doubled and made general managers of naval matters, subject to final decision by Congress, which appointed the officers down to third lieutenant — the «patronage» question being as burning here as in the Continental army. The beginnings of

the American navy were curiously inauspicious for a nation of skilful and daring seamen, and for a body with so brilliant a subsequent record. The officers were largely incompetent, and the men mutinous. A brilliant exception was Captain Manly of the schooner *Lee,* who captured several prizes, including a brig loaded with heavy guns, mortars and tools. Finally, on 25 Nov. 1775, Congress gave up the grisly pretense of being at loyal peace with Great Britain, and declared all ships of war employed against the colonies, and all supply tenders for them, lawful prize; authorized privateering and colonial courts to try prizes; adopted rules and regulations for a Continental navy; and on 13 December directed the marine committee to build and fit out five 32-gun frigates, five 28's and three 24's, by April next. These were estimated to cost $866,666.66, and were to be built at the leading colonial ports from Portsmouth to Baltimore, and elsewhere (Norfolk, Charleston, etc.), if thought advisable. Other vessels might be bought and equipped. On 22 December Esek Hopkins was made commander-in-chief. Among the first lieutenants was John Paul Jones. On 9 November two battalions of marines were authorized. By January eight cruisers had been collected at Philadelphia, and Commodore Hopkins started on a cruise, but was detained six weeks by the ice, and only got clear 17 February. He had been instructed to "annoy the enemy's ships upon the coasts of the Southern States"; but finding nothing of Dunmore's squadron, sailed to New Providence in the Bahamas, where a quantity of British military supplies were stored, stormed the place, and carried off a quantity of stores and 80 cannon, besides the governor and some leading citizens as hostages. On his return he fell in with some armed vessels, which he captured, and the 20-gun frigate *Glasgow,* which, after a spirited fight, escaped. Congress held an inquiry into Hopkins' conduct in June, decided that he had exceeded his instructions, censured him and finally dismissed him. This did not encourage enterprise, and naval service became unpopular. No new naval commander was appointed, the President afterward being given that rank. The vessels, however, did some clever work, and captured many prizes; but the greater part of this service was accomplished by privateers. At the time of the Declaration of Independence our navy consisted of six regularly built war vessels and 19 merchantmen with naval armament, the whole with 422 guns. Against this the British had 78 men-of-war, with 2,078 guns.

Next in importance to the *Bonhomme Richard's* fight with the *Serapis,* the most creditable naval engagement of the war was Benedict Arnold's battle on Lake Champlain. The importance of the naval battles on this inland lake is hardly realizable now; but till the time of railroads the lake was the one route for a large invading expedition between Canada and New York or New England, enabling supplies to be transported where otherwise the mountains or the forests would have made it impracticable. The English had 29 vessels with 89 guns; four longboats with stores; 697 men of the regular navy; and Indian allies. Arnold had 15 vastly inferior vessels, with 88 lighter guns, and about 750 men ignorant of naval service. Several of Arnold's vessels had to be abandoned and destroyed; two were captured; but several were saved in spots the English could not reach, by Arnold's heroic risk of himself. The British loss was about 40, the American about 80. But the battle lost the British the campaign; the struggle had been so severe that Sir Guy Carleton, the commander, did not venture to assail Ticonderoga, and shortly after retired to winter quarters.

The most famous work done by the navy, however, resulted from commerce-destroying in British waters. Our fleets were nearly as much masters of the English Channel as the English were at the time of the *Armada,* though we never had more than three or four ships there at a time; for the English could not protect their own commerce. No other enemy ever disturbed the marine insurance rates, not even France across the channel; but in a short time now they rose to prohibitive rates, and the companies even refused to insure English bottoms at any premium, so that the Thames was crowded with French vessels. The alarm and fury of the English were shown not only in the execrations of "pirate" which they lavished on the lawfully commissioned war vessels and their captains and crews, and in the barbarous misusage of the latter with which they revenged themselves when they captured any, but in the abiding hereditary tradition of their writers: they then invented false accounts of John Paul Jones, and still term him a "notorious pirate," although he was no more a pirate than Nelson, and much less than Rodney, who even turned pirate on his own people. In 1776–77 the *Lexington* was engaged in this work, and in 1778 was joined by the *Reprisal;* but the former was finally captured and the latter foundered. The *Surprise* was then secretly bought from England and fitted out at Dunkirk; but on her beginning to make captures the English government forced the French by threats to give her up. The *Revenge* was then bought, and became even more successful. But the most magnificent success was won by Jones (see BONHOMME RICHARD), in 1778–79. In the former year he closed a wonderfully successful 28 days' cruise in the *Ranger* — from 10 April to 8 May — by capturing the *Drake,* a more powerful vessel than his own. In the latter the marvelous engagement of the *Bonhomme Richard* with the *Serapis,* the most creditable naval victory of the war, dwarfs all else. See JONES, JOHN PAUL.

Meantime Congress had ordered the construction of three 74-gun men-of-war, five large frigates and one or two smaller vessels; but as money ran short, they were never finished. At the end of 1778 the navy consisted of four 32-gun ships, two 28's, one 24, one 20, three 18's, one 12 and one 10 — 14 in all, with 332 guns; while England had on the American coast 89 ships with 2,576 guns. In 1779 the most notable events were the capture on 7 May of seven transports with about 50 guns and some 300 men, by a Boston squadron under Capt. J. B. Hopkins, son of the ex-commodore; that of eight prizes worth over $1,000,000, in July; that in August, by two Continental vessels on a short cruise, of six prizes with 54 guns; and on 7 May, the same day as the first, a most bloody and desperate action of an hour between two 12-gun brigs, the United States *Providence* and the British *Diligent,* in which the latter lost 8 killed and 19 wounded out of a crew of 53,

or over half. In 1779 and 1780 Capt. John F. Williams won two brilliant victories in 14-gun and 18-gun Massachusetts State vessels. But on 13 Aug. 1779 a heavy disaster befell the waning little Continental navy. Three vessels, a 32, a 14 and a 12, accompanied a fleet of Massachusetts privateers to dislodge the English from a fort near the mouth of the Penobscot; but, seven English war-ships coming up to reinforce the three already there, the privateers fled, and the Continental vessels had to be run up the river and destroyed. By the fall of Charleston four more — two 28's, a 24, and the celebrated 18-gun sloop *Ranger* — were captured or destroyed; another had been lost; and at the end of 1779 the navy had but six vessels left, so that it was very hard to run the English blockade. Officers and seamen were scarce also; for the English dreaded the American privateers and naval destroyers so much, few as they were, that they systematically refused to exchange prisoners, and connived at the destruction of the Americans in pestilential hulks or prisons. In October 1780 the *Saratoga,* after taking three prizes, which were recaptured, foundered; and in 1781 the *Trumbull* was captured after a fight against superior force in which she was crippled. But the small remnant still won some victories. The *Alliance* on 28 May 1781 captured a 16-gun and a 14-gun brig; and early in 1782 the *Deane* captured four vessels with 48 guns. In April 1782 was fought a very brilliant action by a privateer, one of the most remarkable of the war: the Pennsylvania State cruiser *Hyder Ally,* Lieut. Joshua Barney, having 16 6-pounder guns and 110 men, engaged the British sloop-of-war *General Monk* with 20 9-pounders and 136 men. Despite this enormous disparity of force — 96 pounds of metal against 180 pounds — the American vessel forced the British to strike in half an hour, with a loss of 20 killed and 33 wounded, against 4 killed and 11 wounded. Another remarkable contest was won by a private Philadelphia cruiser, the *Congress,* off the Southern coast. She had 20 guns, but was manned almost entirely by landsmen, seamen being unobtainable. On 6 Sept. 1781 she fell in with a British 16-gun sloop-of-war, the *Savage,* with her regular complement of seamen. In about an hour and a half, lying so close that the guns scorched the opposing gunners, and shot were thrown by hand, the British vessel was fairly shot to pieces, and forced to surrender, with a loss of 8 killed and 24 wounded, against 30 of both on the privateer. The last naval fight of the war was between the *Alliance,* Capt. John Barry, and a heavy English ship, which the former drove off during a run to Havana. The Continental vessels lost during the Revolution numbered 24, with 470 guns. The British loss was 102, with 2,622 guns. The American navy and the privateers together captured about 800 prizes from the British. British privateers did not capture a single Continental vessel; American privateers captured 16 English cruisers, with 226 guns. Consult Maclay, 'History of the American Navy' (Vol. I, 1893); Cooper, 'History of the Navy of the United States' (1839). See UNITED STATES, NAVY OF THE.

CONTINENTAL SHELF, that part of the ocean bottom covered with shallow water, and extending from the littoral belt out to the 100 fathom line. Beyond this line lies the continental slope, or edge of the continental block, merging into the abysmal seas. The sediments that accumulate on the shelf are often called shoal water deposits. Those that accumulate on the continental slope are termed aktian deposits, and this belt is sometimes called the aktian belt. The sediments of the deep sea are termed abysmal deposits.

CONTINENTAL SYSTEM, a plan devised by Napoleon to exclude Great Britain from all intercourse with the continent of Europe and thus compelling her to acknowledge the maritime law as established at the Peace of Utrecht. The history of the continental system began with the famous decree of Berlin of 21 Nov. 1806, by which the British Islands were declared to be in a state of blockade; all commerce, intercourse and correspondence were prohibited; every Briton found in France, or a country occupied by French troops, was declared a prisoner of war; all property belonging to Britons was accounted fair prize, and all trade in British goods was entirely prohibited. No vessel coming directly from Great Britain or British colonies, or which had been there since the publication of the edict, was to be admitted into any harbor, and all vessels attempting to avoid this edict by false declarations were to be confiscated, with all their goods, as British. The reasons assigned for this decree were, that Great Britain did not acknowledge the international law accepted by civilized nations, but treated every individual belonging to the country of the enemy as if found in arms; made even the crews of merchantmen prisoners of war; extended the right of conquest over merchantmen and private property, and the right of blockade over places and harbors not fortified; over the mouths of rivers; nay, over whole coasts and countries. But many of these measures had always been taken, in maritime ways, even by France herself, as long as she had the means. One great reason for this and all the subsequent decrees of Napoleon was that he considered Great Britain his inveterate enemy and the enemy of the political doctrines which took their rise from the Revolution.

Great Britain immediately directed reprisals against the Berlin decree, first by an order in council of 7 Jan. 1807, by which all neutral vessels were prohibited to sail from one port to another belonging to France, or one of her allies, or to a nation so much under her control that British vessels could not have intercourse with it. Every neutral vessel which should violate this order was to be confiscated with her cargo. A second decree of 11 Nov. 1807 was much more oppressive to commerce. By this all harbors and places of France and her allies in Europe and the colonies, as likewise every country with which Great Britain was at war, and from which the British flag was excluded, were subjected to the same restrictions as if they were closely blockaded; all commerce in the manufactures and productions of such countries was prohibited, and vessels engaged in such commerce were to be confiscated, as also all those vessels whose certificates showed that they were built in the enemy's country. Another order in council declared the

sale of vessels by the enemy to neutrals unlawful, and the intended transfer of property void.

Hardly were these orders promulgated when France made counter-reprisals. By a decree of Milan of 17 Dec. 1807, aggravated by a decree of the Tuileries 11 Jan. 1808, every vessel, of whatsoever flag, which had been searched by a British vessel, and consented to be sent to Great Britain, or had paid any duty whatever to Great Britain, was to be declared denationalized, and to have become British property; and in every case such denationalized vessel, as also those which had broken the blockade declared against the Ionian Islands, or had sailed from a British harbor or British colony, or those of a country occupied by the British, or which were destined for any such ports, were declared good prize. By the Treaty of Tilsit (1807) Russia consented to close her ports to English commerce. In order the more effectually to annihilate the British commerce, the tariff of Trianon, respecting colonial goods, was proclaimed 3 Aug. 1810. This was extended by another decree of 12 September of the same year, and both were followed by the decree of Fontainebleau, 18 October of the same year, directing the burning of all British goods. These decrees were to be executed with more or fewer modifications in all countries connected with France. The consequence was that the price of colonial goods rose enormously; a regular smuggling trade was carried on at different points; for instance, at Heligoland, which was sometimes so crowded with persons concerned in this business that a ducat was paid for a barrel to sleep in; thousands of substitutes for colonial goods, particularly for coffee and sugar, were invented, and a variety of manufactures grew up on the Continent which were the germs of very extensive and flourishing branches of industry. The system was abolished immediately after the fall of Napoleon. But its continuance on the English side was one of the causes of the War of 1812. Consult Mahan, 'The Influence of Sea Power on the French Revolution and Empire' (Boston 1894); Thiers, 'Histoire du consulat et de l'empire' (Paris 1845–62); Cime, 'Etude sur les tarifs de douane et les traités de commerce' (Paris 1875); Adams, Henry, 'History of the United States' (New York (1889–91).

CONTINENTALS, or CONTINENTAL ARMY, the army of the United States during the Revolution. In May 1775, after the battle of Lexington, the Provincial Congress of Massachusetts requested the Continental Congress to assume control of the forces which had gathered around Boston. Further outside pressure led the latter Congress in June to vote for raising a «Continental army» (the name «Continental» in all these cases expresses the hope, long entertained, that Canada would join the revolt), and for a loan of $2,000,000 to support it. On the 15th George Washington was appointed commander-in-chief; then four major-generals were appointed, Artemas Ward, Charles Lee, Philip Schuyler and Israel Putnam; and an adjutant-general, Horatio Gates. Lee and Gates were bitterly opposed in Congress, and were only confirmed by Washington's influence, as men of approved military capacity. It is curious that Congress was right and Washington wrong, and that Lee's treachery and Gates' incompetence and intrigue nearly ruined the cause and Washington together. The brigadiers appointed were general officers in colonial service, with two others; and the inferior colonial officers were confirmed in their rank and shortly given Continental commissions. For commissary-general was chosen Joseph Trumbull, son of the governor of Connecticut, Washington's right-hand man and adviser, who kept a great general store in Lebanon. There was a further reason for this. The food surplus of the country came mainly from three great valleys,—the Connecticut, the Hudson and the Delaware; the last two were held by, or liable to raids from the British during most of the war, and the Connecticut Valley was the one rich farming country which the British could not molest. Hence the first two commissary-generals were both Connecticut merchants. Washington appointed his aide, Thomas Mifflin of Pennsylvania, quartermaster-general; and Dr. Benjamin Church of Boston was made director of the army hospital. There was no paymaster-general till late in 1776, when William Palfrey of Boston was appointed. On 12 June 1776 Congress voted to appoint a «Board of War and Ordnance» of five members; in 1777 this was changed to a «Board of War,» to consist of three persons not members of Congress. This board has not left an enviable historical reputation; but it lacked neither ability nor patriotism. In part its troubles were due to civilian misunderstanding of and contempt for military claims and feelings; in part to the insistence by the States on their share of army patronage, as now of civil patronage, which drove some of the best generals from the service and contributed to Arnold's treason.

The army was constituted by taking into colonial pay the militia regiments of the various colonies, and enlisting others for a year. The number on the war office rolls during 1775 was 27,443, besides an estimate of 10,180 militia for a few months' service during 1776, 46,891 regulars, 16,700 militia as before. Had these all been in the field and good troops, and well equipped, they would have been fairly sufficient, though not what could or should have been raised; but half or more were on paper, the material was poor, the equipment insufficient and the whole system incompatible with effectiveness. The term of enlistment was too short for the soldiers to learn their business; the militia absolutely refused to submit to discipline, and their insubordination affected the regulars. Washington during the campaigns of 1776 urged upon Congress a plan for a permanent army; that body sent a committee to the camp at Harlem Heights, and drew up a scheme generally in accord with his views, which Congress adopted. The «armies» of different sections were to be consolidated into one body, of 88 battalions with 750 men each, to be raised in the States according to population and resources; besides a Canadian regiment to be called «Congress' Own.» The largest numbers, 15 battalions each, were to come from Massachusetts and Virginia. The men were to be enlisted for the war, with a bounty of 100 acres of land each at the end; officers, higher amounts; colonels, 500; and $20 bounty for each recruit. The States were to enlist their quotas, arm and equip them; and to appoint the officers from colonel down though Congress

was to commission them. But the plan worked slowly and poorly. Enlistments for the war were so few that a three years' term was substituted; to stimulate even these, Massachusetts began and other States continued the policy of greatly increasing the bounties, and towns and counties bid still higher; but this rather made the process slower, men waiting to see how high the bids would go. Washington was shortly invested with dictatorial powers to remove any officers under brigadier, and fill the vacancies at his discretion; and allowed to raise 16 extra battalions. This somewhat strengthened his scanty lines, and enabled him in a slight degree to rectify the mischief done by the State patronage, give commissions to good officers, and keep others from retiring. But even so, and despite incessant drafts from the militia, the total number of soldiers enrolled in 1777 was but 34,820 regulars and 10,100 militia; in 1778, 32,899 and 4,353; in 1779, 27,699 and 5,135; in 1780, when the Carolinas and Georgia were in British hands, and none of their troops were on the roll, 21,015 and 5,811; in 1781, when Cornwallis surrendered, 13,292 and 7,298. It would seem that if the British could have held out a little longer, or sent one more army to America, the Continental army would have melted into nothing without the country taking pains to keep it up.

The reason was not lack of men, nor any ruinous exhaustion of resources; it was simple administrative anarchy (see CONFEDERATION, ARTICLES OF), which could not collect and distribute the resources we possessed, and which left the soldiers half fed, less than half clothed, and for long periods unpaid. This was increased by a jealous dread of the army itself (see CINCINNATI, SOCIETY OF THE), bred by historical experience which they had as yet no other to countervail; they appreciated victories, but were not inclined to pinch themselves for daily supplies. In 1777 the soldiers' back pay was settled up in Continental money, at about 12 for one, though Massachusetts made good a part of the depreciation. Arrears steadily accumulated till the end of the war, though in 1778–79 a half-pay system for seven years was provided for the officers, and a gratuity of $80 for the men. In January 1781, the Pennsylvania regulars struck, and were pacified with difficulty and by certificates for their pay; the New Jersey troops followed suit; and Congress in alarm made requisition on the States for $879,342 to pay the arrears. About half the amount came in, and Massachusetts and New Hampshire sent gratuities to their men; but the rest lagged. About this time the Articles of Confederation were adopted, making the consent of nine States necessary for appropriations; Congress was even more helpless than before; and as the time of a general disbandment drew near, the officers began to fear that it was intended to turn them off without paying them, and if they did not receive it while in the field they never would. Meantime Congress was debating the subject. The later Federalist party wished to fund the army dues as well as the other public debt, and give the army interest-bearing certificates; the decentralizers wished to leave it to the States to settle each with their own troops. The officers, finding the half-pay project highly unpopular, wished to commute it for a lump sum, in cash or securities. About this time, 10 March 1783, an anonymous letter called a meeting of the officers in camp at Newburg, and an anonymous address suggested that if Congress refused justice, they should desert the country in a body, under Washington's lead. Washington denounced this call as seditious, but called a meeting himself, at which his influence kept patriotism uppermost; but he wrote urgently to Congress, and it finally agreed to commute the half-pay into five years' full pay in certificates at 6 per cent interest. The States were very indignant at this, New England especially denouncing the whole scheme of half-pay: the Massachusetts legislature passed a resolution that it tended to «raise and exalt some citizens in wealth and grandeur to the injury and oppression of others.» The soldiers were furloughed on three months' pay till the British should evacuate New York, when they were discharged. The number of troops nominally furnished by each State is as follows:

Massachusetts, 69,907; Connecticut, 31,939; Virginia, 26,678; Pennsylvania, 25,678; New York, 17,781; Maryland, 13,912; New Hampshire, 12,497; New Jersey, 10,726; North Carolina, 7,263; South Carolina, 6,417; Rhode Island, 5,908; Georgia, 2,679; Delaware, 2,386. Total, 231,791. Adjutant-generals: Horatio Gates of New York, Joseph Reed of Pennsylvania, Timothy Pickering of Massachusetts, Alexander Scammell of New Hampshire, Edward Hand of Pennsylvania. Quartermaster-generals: Thomas Mifflin of Pennsylvania, Stephen Moylan of Pennsylvania, Mifflin again, Nathanael Greene of Rhode Island, Timothy Pickering of Massachusetts. Commissary-generals: Joseph Trumbull of Connecticut, Jeremiah Wadsworth of Connecticut, Ephraim Blaine of Pennsylvania. Director-generals of hospitals: Benjamin Church of Massachusetts, John Morgan of Pennsylvania, William Shippen of Pennsylvania, John Cochran of New Jersey. Paymaster-generals: William Palfrey of Massachusetts, William Pierce of Georgia. Inspector-generals: Thomas Conway, Baron Steuben. Chief engineers: Louis L. Du Portail, Thaddeus Kosciusko. See UNITED STATES, ARMY OF THE.

CONTINGENT, a name often given to the quota of troops furnished by each member of a number of states composing a federation, or by each organization forming an army or navy.

CONTINUATION SCHOOLS, the term applied to those systems of training which are adapted to people already at work in business or industry, especially for girls and boys between the ages of 14 and 18. The original purpose of the schools was to provide that general education of which forced entrance into business at an early age deprived the workers. The development of the schools has been chiefly along the lines of substitution of further industrial training in place of the general education and of day in place of night classes. The movement began in Germany where such schools in some form existed for many decades, their general and national character having been developed since 1870. They are voluntary — it is left entirely to the discretion of each local authority whether such a continuation school be established and the form, within reasonable limits, it may take. Two clauses in the Imperial Industrial Law of 1891 provide a limited measure of agreement. Clause 120 re-

quires employers of labor to grant to employees under 18 the necessary time to attend continuation classes in the daytime. Classes on Sunday are only permitted in exceptional cases. Clause 142 allows (but does not compel) a local authority to make attendance at a continuation school obligatory for all males under 18 not attending an approved secondary or trade school, and throws the responsibility for such attendance on the scholar's parent or employer, usually on the latter. Since 1891 the system has spread in all sections of Germany and become practically obligatory. Girls are brought within the scheme, but almost always for domestic training only. Apparently two distinct lines of thought control the authorities. On the one hand, it is held that teaching should be definitely vocational — that is, specifically applied to the scholar's chosen calling. On the other, such a program of teaching is preferred as is calculated to produce a good citizen. The one demands technical skill, the other general efficiency. The former has moved in the direction of elaborately-equipped trade continuation school buildings. The latter is a very numerous class, especially in Prussia, and has hitherto been content with makeshift arrangements in elementary school buildings.

Two distinct types of buildings have been evolved. Examples of the first may be seen in the central continuation school at Bonn and in the central and northern continuation schools at Frankfort-on-Main. All erected within the last few years, in none is there any trade teaching properly called. The first contains rooms for cookery and type-setting, the second a number of spare rooms in the basement eventually to be utilized for workshops, and the third rooms for cookery. In Bonn boys and girls are taught in the same building; in Frankfort they are separated. There is ample provision for the teaching of applied drawing and applied science; but most significant in these three examples is the generous provision for recreation. There are large rooms, artistically decorated and well furnished, where concerts and dances are held and lectures given on Sundays and in the evenings, as well as smaller rooms or alcoves for reading and games. In Munich, where trade-teaching is more conspicuously developed, is less external evidence of this social side of school life, and the buildings approximate very closely to the ordinary technical-school type. But Munich in providing scattered district schools obviates as far as possible the long journeys and waste of time involved by a huge central building.

In England continuation schools, chiefly in the form of evening classes, have spread more and more. They are not obligatory. Owing probably to the lack of expert teachers, the system has not proved as satisfactory as desired, but its weak points will be improved in time. In the United States, the plan has been adopted in many cities with considerable success and is a hopeful feature of American education. It adapts itself largely to local needs and admits of varied forms. Another happy feature is the prominence attached to the teaching of foreigners chiefly in evenings as an integral part of the course. The employers of large corporations, recognizing the value of further training, often provide such schools within their own establishments. Ireland has a form of continuation school, which has made some headway since 1915, due to the Catholic Working Boys Technical Aid Association of Dublin which organizes social centres and continuation classes throughout Ireland.

CONTINUITY OF STATE OF MATTER. See CRITICAL POINT.

CONTINUOUS VOYAGE. The doctrine of continuous voyage in international law was invented by Lord Stowell in the early part of the 19th century to meet the case of neutral vessels which, in the war between Great Britain and France, endeavored to evade the rule prohibiting neutrals from engaging in the enemy's carrying trade. This evasion was sought by interposing a neutral port between the point of departure and the forbidden destination. It being unlawful for neutral vessels to trade between a French colonial port and a home port in France they attempted to legalize the voyage by breaking it at a neutral port, usually in the United States. Lord Stowell held, however, that the two voyages were in effect one and the same, and therefore illegal, although each separate voyage was in itself legal. During the Crimean War the French prize courts extended the doctrine of continuous voyage to the carriage of contraband and such cargoes, bound from one neutral port to another, were condemned whenever the evidence showed that the ultimate destination was in fact a port of the enemy. During the American Civil War the courts of the United States applied the doctrine on a large scale, likewise, to the carriage of contraband and blockade running. Thus British ships, with their cargoes, bound from England to the neutral ports of Nassau or Matamoras, were condemned whenever the evidence showed that the eventual destination was not a neutral port but in reality a port in the Confederacy. British writers on international law unanimously denied the legality of such an extension of the doctrine of continuous voyage and the British prize courts took the same view. Thus in the case of the *Immina* decided at the end of the 18th century, Lord Stowell refused to condemn a vessel bound from Dantzic to Emden, both neutral ports, notwithstanding the fact that Emden was situated only five miles from the frontier of Holland, a country with which England was then at war and although it was notorious that the goods were to be reforwarded from Emden to the enemy country. During the Boer War, however, Great Britain for the first time abandoned her early attitude and undertook to apply the rule which her courts and text writers had formerly condemned, and seized a number of German vessels bound for the neutral port of Lorenzo Marquez

in Delagoa Bay, on the ground that the real destination of the cargoes was enemy territory (The Boer Republics). During the European War the doctrine of continuous voyage was applied by Great Britain on an extensive scale to the carriage of goods between the United States and the ports of various neutral countries adjacent to Germany and Austria. The Declaration of London sanctions the extension of the doctrine of continuous voyage to the transportation of *absolute* contraband but forbids it in the case of *conditional* contraband, except where the belligerent has no sea board. Likewise it forbids the application of the rule to blockade running. Article 35 of the Declaration lays down the rule that conditional contraband is not liable to capture except when found on board a vessel bound for territory belonging to or occupied by the enemy, or for the armed forces of the enemy, and when it is not to be discharged at an intervening port. But the British order in council of 29 Oct. 1914 modified this provision so as to extend the rule of continuous voyage to the carriage of conditional contraband and also reversed the established rule by placing on the owner rather than upon the captor the burden of proving an innocent destination. The effect of the order in council was to obliterate the distinction between absolute and conditional contraband — a distinction which had already been largely abolished by putting on the list of absolute contraband many articles which were not so by their nature. The American and other neutral governments protested against the extension of the doctrine of continuous voyage to the carriage of articles of conditional contraband between neutral ports and the establishment of presumptions of hostile destination which, it declared, were based on suspicion rather than upon evidence. Cargoes of conditional contraband shipped from American ports to the ports of Denmark, Holland, Norway and Sweden, it was argued, could not lawfully be presumed to be intended for the use of the enemy. There was a large local demand in all these countries for such goods — a demand which had been largely increased by the cutting off of their European sources of supply on account of the war — and it was impossible to admit the right of a belligerent to determine what proportion of such shipments were intended for local consumption and what proportion was intended to be forwarded for the use of the enemy. If after such goods were delivered and became a part of the common stock of the neutral, they were subsequently resold and reforwarded to a belligerent, it was in consequence of a new destination and the doctrine of continuous voyage did not apply.

To this argument the British government replied that it was unable to admit the contention that if a belligerent was so circumstanced that his commerce could pass through adjacent neutral ports as easily as through ports in his own territory, his opponent had no right to intercept such commerce. The position of Great Britain was analogous to that of the United States during the Civil War; the enemy was flanked by neutral countries through whose ports a steady stream of supplies was pouring in for the use of the enemy, and following the practice of the United States during the Civil War, Great Britain was endeavoring to cut off this supply by extending to its carriage the doctrine of continuous voyage, that is, it was endeavoring to prohibit neutrals from doing indirectly what they could not do directly. Under the circumstances the right of blockade and the right to capture contraband goods going to the enemy would be largely illusory unless the injured belligerent were allowed to apply the rule of continuous voyage to such traffic and seize cargoes whose ostensible destination was neutral territory but whose real destination was armed forces of the enemy. Manifestly the right of a belligerent to thus interfere with trade between neutral countries involves a serious encroachment on the rights of neutrals, but so long as the right of belligerents to blockade the ports of the enemy and intercept contraband trade between them and neutrals is admitted it would seem difficult to deny their right to apply a rule without which the weapons of blockade and contraband would in many cases be worthless. (See also BLOCKADE; CONTRABAND; SEARCH, RIGHT OF). Consult the authorities cited under BLOCKADE; CONTRABAND; and RIGHT OF SEARCH.

JAMES W. GARNER,
Late Professor of Political Science, University of Illinois.

CONTORNIATI, kŏn-tôr-nē-ā'tē, ancient medals which have occupied the attention of antiquarians for a long time, and, on account of their rarity, are highly esteemed in cabinets. They are formed of a thin plate of metal (not of two different sorts, as is often supposed) with a flat impression. They differ from other ancient coins by having a furrow upon both their sides, where the others have a wreath of pearls. These hollowed lines (It. *contorni*) may have occasioned their name. Another characteristic of genuine *contorniati* is a cipher composed of the letters EP or PE, of which no satisfactory explanation has as yet been discovered, together with numerous impressed characters, and a great number of palm branches, the cavities of which are often filled with silver. They are also added by a second hand, and thereby are essentially distinguished from the "monograms," so called in the language of the mint. They resemble the *signa incusa* (*contremarques*) on the Roman medals. All the *contorniati* are of bronze, and equal in size to the large bronze coins called *medaglioncini* by the Italian collectors. Their form is various, their workmanship rude and their inscriptions are frequently different from the usual curial style upon the ancient coins. From these circumstances we may conclude that they did not belong to the age of the Roman emperors whose image they bear, but to a later one. Eckel, in his masterly treatise on the contorniati, follows the opinion of Morelli and Mahudel, who consider them to have been made from the reign of Constantine the Great to that of Valentinian. It has been ascertained that they were not struck by public authority; and the ancients have transmitted no account of their destination, which must, therefore, be left to conjecture. The frequent representations of race-grounds, palms, men shouting to the charioteers, and even the images of the emperors upon them, make it probable that they were distributed as tickets of admission or as certificates to successful competitors in

the games at the circuses in Rome and Constantinople. Consult Smith, 'Dictionary of Greek and Roman Antiquities.'

CONTOUR, kŏn'toor, the outline or defining line of any figure or body; also the horizontal outline of works of defense. When the conformation of the ground or works is described by contours or horizontal sections, these sections are taken at some fixed vertical interval from each other suited to the scale of the drawing or the subject in hand, and the distances of the surface at each interval above or below some assumed plane of comparison (usually sea-level) are given in figures at the most convenient places on the map. The contour lines, that is, represent the shore lines that a rise in the ocean would cause it to assume. Of course, embayments of this shore line correspond to valleys that would be drowned, and promontories to ridges. Contour lines close together mean that a considerable rise in the sea-level would have a comparatively slight effect in pushing back the shore line, which must therefore be situated on very steep ground. As water always flows down hill by the steepest path, and as a line squarely across the contour lines will meet more of them in a given interval than one that meets them slantingly, it is clear that the lines by which the rain is carried off the ground meet all the contour lines at right angles, and that consequently the streams must do likewise. This relation between streams and contour lines, coupled with the fact that streams flow along the bottoms of valleys, and consequently pass through the inmost points of embayments in the contour lines, is of the utmost value to the topographer, who always bases his contouring of a region on its drainage.

Two contour lines cannot cross except where there is an overhanging cliff. A contour line cannot terminate; it must either be closed or run off the map. A closed contour line either encloses a hill-top or a depression, which in general has no stream leading from it. Such depressions are rare except in very dry climates, and even there usually contain a salt lake or marsh, so that confusion between hills and valleys is not likely to arise in reading the map.

It is possible to determine within fairly close limits whether of two points given on a contour map one is visible from the other. This is one reason for the immense superiority of contour maps over all others in military operations.

The contour interval varies according to the scale and purpose of the map and the nature of the terrain. In the United States army, maps with a scale of 12 inches to the mile are supposed to have a contour interval of five feet; those with a scale of six inches to the mile have a contour interval of 10 feet; those with a scale of three inches to the mile have a contour interval of 20 feet, and those with a scale of one inch to the mile have a contour interval of 60 feet. This makes the distance between the contour lines dependent only on the mean slope of the ground and not on the scale of the map. In mountainous country, however, the contour intervals may have to be doubled or trebled to obtain a legible map. See MAP; SURVEYING; and the map of a part of the Housatonic quadrangle in GEOLOGICAL SURVEY.

CONTRABAND. Contraband (from *contra bannum* or *bandum*, contrary to the ban or edict), is a term applied to certain articles which international law allows a belligerent to seize and confiscate even when found on neutral vessels, and which are being transported for the use of the enemy. By means of a blockade (q.v.) a belligerent may cut off *all* neutral trade and intercourse with his enemy; through his power to capture contraband goods he may prevent neutrals from furnishing the enemy with such goods as by the law of nations are regarded as contraband. These are the two principal weapons which international law places in the hands of belligerents for cutting off the over-sea commerce of their enemies, the effectiveness of each depending, of course, upon the sea power of the belligerent which employs them. Both may be resorted to at the same time, and in the hands of a nation which controls the seas they may become a means of reducing the enemy to starvation and thus compel him to surrender. International law, however, allows the citizens or subjects of neutral powers to carry on at their risk contraband trade with either or all belligerents, subject to the rights of the injured belligerent to capture and confiscate all such articles as fall within the category of the contraband. Their government is not bound to prohibit them from engaging in such traffic; on the other hand, it is not their duty to intervene to protect them from losses which they may sustain from having their goods captured by one of the belligerents.

Different governments have held different views as to what articles properly fall within the category of contraband and the policy of the same state has not infrequently varied from time to time, sometimes quite inconsistently. Grotius, the first great writer on the law of nations, classified articles into three groups: first, absolute contraband, or those used exclusively for war purposes; second, innocent goods, or those incapable of being used at all for military purposes; and third, conditional contraband, or those susceptible of being used both for purposes of peace and war. This classification has in practice been generally observed by belligerents, although there has been no agreement as to what articles fall in each class. The subject was discussed at the second Hague conference in 1907, but no decision was reached. It was again considered at the London Naval Conference of 1908–09 with more success, but the declaration adopted by the conference has not been ratified by any of the governments there represented. At the outbreak of the European War most of the maritime powers of Europe put the Declaration into effect with certain modifications, some of which related to the subject of contraband. The Declaration, although unratified, represents the nearest approach to an agreement among the maritime powers that has ever been reached. It enumerates a list of articles embracing such things as arms, munitions, armor plates, warships, military clothing and harness, pack and draft animals, etc., which are declared to be absolute contraband. In the second place it contains a list of articles declared to be conditional contraband, and embracing such things as food-stuffs, cloth, coin, vehicles, air-craft, fuel, barbed wire, horseshoes, field glasses, etc.; and the third group embraces various articles

which are declared not to be contraband at all, such as raw cotton, wool, silk, flax, hemp, rubber, rosin, rawhides, metallic ores, paper, soap, agricultural machinery, precious stones, clocks, feathers, etc. These lists, however, are not considered as absolutely fixed, for article 23 of the Declaration allows belligerents to add other articles used "exclusively for war purposes" to the list of absolute contraband, and article 25 permits similar additions to be made to the list of conditional contraband. It does not, however, permit the placing on the list of absolute contraband of articles which are susceptible of both innocent and warlike use nor does it allow belligerents to treat as contraband, either absolute or conditional, articles which are susceptible only of innocent use. The disregard of this rule by the entente allies during the European War in treating cotton, air-craft, copper, rubber, glycerine, zinc, lead, wool, tin, castor oil, and various other commodities as absolute contraband evoked a protest from the German government and was the subject of complaint in the United States and other neutral countries.

The rule governing the liability of contraband to capture varies according to whether the goods belong to the class of absolute or conditional contraband. Under the Declaration of London absolute contraband is liable to capture if it is destined to any place within the enemy country or the territory occupied by him; on the other hand, conditional contraband is liable to capture only when destined for the use of the armed forces or for the government of the enemy state, but it is presumed to be destined, when the goods are consigned to the enemy authorities, to a government contractor or to a fortified place or a naval base within the enemy country. These and other rules of the Declaration are admittedly unsatisfactory. The presumptions which it establishes in regard to hostile destination are vague; nothing is gained by condemning conditional contraband goods destined to a government contractor and allowing those consigned to a private merchant to go free, since the latter can sell to the government as readily as the former may; again every important port is fortified, yet the existence of fortifications is no indication as to the ultimate use of the goods; almost every place in this age of railways may serve as a "base" of supplies; finally nothing is gained by preventing an enemy from obtaining supplies from a "fortified" place, a "base" or from a government "contractor" when he may obtain them with equal readiness from private dealers, through the power of requisition. The penalty for carrying contraband is the confiscation of the goods; likewise, the vessel carrying the goods may according to the Declaration of London be condemned if the contraband constitutes more than half the cargo. Whether the captor may sink the ship with its cargo if he cannot take it in to a home port was raised during the Russo-Japanese War in 1904 when the Russians sank the *Knight Commander,* a British vessel laden with contraband goods destined for Japan. The British government denied the legality of the act and demanded the payment of an indemnity by the Russian government. The sinking by a German cruiser during the European War of the American sailing vessel *William P. Frye,* laden with grain destined for England, evoked a protest from the government of the United States. In consequence of treaty stipulations between the United States and Germany, the German government agreed to compensate the owners of the vessel. But in the case of the *Maria,* a Dutch vessel carrying contraband to England and sunk by a German cruiser, the German government declined to make compensation to the owners of the ship, there being no treaty between Germany and the Netherlands similar to that between Germany and the United States. Many other neutral vessels laden with contraband were sunk by German naval commanders.

Inasmuch as the majority of controversies between belligerents and neutrals are usually connected with trade in contraband and in view of the lack of agreement concerning what is and what is not contraband, it has been proposed to abolish the right of belligerents to interfere with such trade and to leave them merely the right of blockade. Such a proposal was made by the British delegation at the second Hague conference in 1907. The supporters of the British proposal pointed out that the right to interfere with trade between neutrals and belligerents is out of harmony with modern conditions; that the number and variety of contraband articles have greatly increased; that the increased size of ships has made search on the high seas more and more difficult, thus necessitating the taking of them in to distant ports and subjecting shippers to ruinous delays; and that improved railway facilities have made it impossible to prevent contraband from reaching belligerents. As evidence of the growing dissatisfaction with the existing rules in respect to the right of belligerents over contraband trade, it may be remarked that the British proposal received the support of 26 of the 35 states which voted on the proposition, only five voting against it. Another proposal which has been widely approved is the abolition of conditional contraband and the substitution of a single list of articles, by general agreement, these to be liable to capture if consigned to any person or place in the enemy country. See CONTINUOUS VOYAGE; RIGHT OF SEARCH; BLOCKADE.

CONTRABASS. See DOUBLE BASS.

CONTRACT. Of the positive rules obeyed by men, in a society which has reached the stage in which we live, the greater part are made by contract; the lesser only are made by imperative law. Indeed, the speculative and philosophical writers of the 18th century on sociology and politics, under the influence of Montesquieu and Rousseau, were filled with a notion of a "social contract" as the origin of law. Obedient to the impulse thus given, they assumed that the form of contract resting upon the mere consent of the parties was the original. The assumption was the outcome of their reasoning that social development began with a state of nature, in which innocence and simplicity prevailed, to a state of increasing complexity and sophistica-

tion. Accordingly the simpler forms were believed to pertain to the older and more natural order of society. The history of contract shows the truth to be exactly opposite. The «ceremonial» contract, in which the failure to observe a mere technical formality was fatal to the obligation, is the real original. There is nothing in early times like the interposition of law to compel the fulfilment of a mere promise. The idea of the State intervening to enforce obligations resulting from one man's reliance on the word of another was of slow growth, and its realization was one of the latest fruits of civilization. Early law sanctioned only that promise which was solemnized by a prescribed ceremonial; and, when duly solemnized, a promise became a contract, which the law recognized and would enforce, even though obtained through duress or deception. Informal engagements the Roman lawyers called *pacts*, to distinguish them from «transactions with the copper and balance,» which alone were entitled to the name of «contracts.» The distinction is observed in our law to this day. The delivery of a clod of earth is no longer an essential in the conveyance of land, but deeds and sealed instruments in general are still differentiated from other contracts; and the distinction is not merely verbal — it is radical, setting «specialties,» as sealed contracts are called, in a class apart with respect to their legal validity as well as in their form. A «specialty» or sealed instrument, for instance, «obtains validity from its form alone, not from the fact of agreement or consideration moving»; it cannot be revoked after tender, even though the offer contained therein be not immediately accepted; and one who accepts the tender of a deed assumes the obligations therein imposed on him, even if he have given no expression to his intention to do so. Equity, of course, will give relief from a contract by specialty when obtained by fraud, under duress, etc. All contracts not under seal are called parole contracts. A parole contract may be made in writing or orally. Another distinction which is usually made — that between executed and executory contracts — might probably be eliminated. When a man goes to a jeweler and buys a watch and pays for it, a contract has taken place, but it has been extinguished in the very act of making. He has the watch and the jeweler has the money; each has acquired a right of possession and ownership, one to the cash and the other to the timepiece. These rights were created by a contract, to be sure, but a contractual obligation between them no longer exists,— neither party has any duty to perform to the other. An executed contract calls for no intervention of the law, though the law may be appealed to for the protection of the parties in the rights thereby acquired. The jeweler might have warranted the watch, but that would be a new contract, superadded to the executed contract of sale. The purchaser might have paid for the watch with counterfeit money, but in this event the vendor would have his choice between a reopening of the transaction, thereby making the contract of sale once more an executory contract, or he could pursue his remedy on the new right vested in him by the tort of the vendee. This new right, however, having arisen from an obligation *ex delicto*, the proceeding taken thereon would not be for the enforcement of a contract. The law of contracts, strictly speaking, is concerned only with promises or agreements which remain to be performed in whole or in part — in a word with executory contracts. The very definition of a contract, as «an agreement which creates an obligation,» implies the exclusion of agreements all the conditions of which have been fulfilled and which have resulted in the creation of rights *in rem*. An obligation which has been performed is no longer an obligation. A more appropriate distinction than that between executed and executory agreements would be one between contracts which create rights *in rem*, such as rights of possession and ownership enforcible against the whole world, and those which create rights *in personam*, enforcible only against the person obligated.

Law of Contracts.— Almost every conceivable human relation or right may be subject matter of a contract, though contracts contravening public policy would be absolutely void, and not merely voidable for their illegality. A person could not sell himself into slavery, nor make an enforcible agreement to commit a crime; to do an act forbidden by statute, nor to do a civil wrong. The compounding of, or an agreement not to prosecute, a felony, or to procure legislation by corruption, to promote litigation (champerty), etc., would not be contracts; but would be crimes. But an agreement would not be illegal even though the thing agreed to be done should be unwise, unreasonable or absurd. The essentials of a contract are (1) two or more parties, for a man cannot make a contract with himself, and an agreement between two departments of the same corporation would be a nullity; (2) there must be a common intention, which must have been communicated from one party to the other; (3) what is agreed to must be possible and legal; (4) the agreement must have been expressed in some manner, or must be inferable from the acts of the parties; (5) the agreement must either be evidenced by a solemn formality — the sealing and acknowledgment of a bond or a deed; or there must be some fact which affords a motive for the making of it — in the language of the lawyers, «a consideration moving.» All agreements spring from an offer and its acceptance. The acceptance must be unconditional, for, if it is conditional, the acceptance is, in effect, a new offer; the minds of the parties have not met and there has been no agreement. Acceptance must be contemporaneous with the offer, or the latter may be withdrawn at any time before it has been accepted. A bid at an auction, for instance, has been held not to bind the bidder until the hammer has fallen. A party making an offer by mail, however, cannot withdraw the same after the party of the other part has sent his acceptance by post; though an offer by mail may be countermanded by telegraph or phone before it has been assented to. An offer made in an instrument under seal cannot be revoked even though not immediately accepted by the party to whom the tender is made. The consensus of the parties must be real. Absence of consent not merely avoids an agreement but renders it a nullity. There is no real consent when one of the two parties does not mean the same thing as the other, or when an unavoidable mistake has been made — as where the object of an agreement does not exist, or where an agreement is made to buy a cargo «to arrive

ex *Peerless*," there being two ships of that name, one of which was intended by the buyer and the other by the seller. Fraudulent misrepresentation, of course, invalidates consent of the defrauded party and vitiates the agreement. Mere exaggerations of a vendor crying his wares are not necessarily fraudulent; representations are fraudulent in law only when made recklessly, with knowledge of their falsity or without belief in their truth. To invalidate consent it must have been materially induced by the misrepresentations. Only where the utmost good faith is required, as where one party stands in a fiduciary relation to another, may even the innocent misrepresentation or non-disclosure of facts invalidate an agreement *ab initio*. When the consent of a party is obtained by undue influence no contract has been made. Threats of injury to or the withholding of property, when made by a person in a position to dictate, constitute undue influence — as, where a banker refuses to honor the check of a customer unless the latter accedes to a false or fraudulent claim; or a water company refuses service unless a promise is made to which it has no right. Consent is nugatory, of course, when given under duress, meaning a threat of bodily harm to the promisor or the restraint of his liberty. The matter agreed upon must be possible of performance as well as legal. An agreement to jump over the moon would not be a contract; but a promise to build an aeroplane that could cross the Atlantic in four days would be, the performance of the promise being, conceivably, possible. A physical impossibility is not necessary; a practical impossibility is sufficient to avoid an agreement — for instance, to recover a ring known to be lying at the bottom of the sea. An agreement which imports to have a legal effect unknown to the law is void. An agreement may be expressed either in writing or orally, or one may be inferred from a course of conduct. The latter is called an "implied contract." The intention of the parties must have been communicated from one to the other. In an old case of the time of Edward IV it was said by the court in reference to an unexpressed acceptance, "your having it in your own mind is nothing, for it is trite law that the thought of a man is not triable, for even the devil himself does not know what the thought of a man is." In a developed system of laws it is not necessary that the offer and acceptance be made by the parties face to face. They may be communicated by post or by telegraph or telephone, by messenger or other go-between. A contract made by mail need not be contained in its entirety in one letter and the answer thereto; it may be the outcome of a long correspondence and may be made partly in writing and partly by word of mouth. A contract, unless it be a "specialty," need not follow any prescribed form, and it may be made through agents. Contracts are sometimes said to be "implied in law." The term is not happily chosen, for an examination of the cases shows that obligations by legal implication do not spring from contracts at all. For instance, when one receives money which should have been sent to another he is under obligation to turn it over to the person legally entitled thereto. To say that he is under an implied contract to pay is illogical, however, — for, where is the contract? After all the requirements above enumerated have been satisfied, something is still necessary to the making of a legal contract. Either some legally prescribed formality must be observed, as in the case of a sealed instrument; or, in respect to contracts not under seal, there must be a consideration. A parole promise, for which no consideration has passed or is to pass, is a *nudum pactum*, and is unrecognized by the law. No action can be founded on the same. A pecuniary consideration, however, is not necessary to support a parole contract. Any benefit to the party promising or any loss or detriment to the promisee would be a sufficient consideration. The benefit need not flow from promisee to promisor; this or the detriment or loss suffered by the promisee may be to the advantage of a third party and would still be regarded a good consideration. A promise to do or to forbear doing something would be a good consideration just as would be the deed or the forbearance itself. An offer to perform personal services and acceptance of the offer with a promise to pay for the services would make a mutual contract. The confidence reposed in one who undertakes a service may be a sufficient consideration. Thus, one who was entrusted with the removal of wine casks from one place to another, though without pay, was held to have violated a contract when he performed the task so negligently that damage resulted. On the other hand, the consideration must have some real value. Marriage has been held by our gallant judges to be the most valuable of all considerations; it will give legal support to the most extravagant ante-nuptial promises. The contract of marriage is of any and all classes; it may be ceremonial and formal or merely parole; it is an executed contract in so far as it has resulted in the creation of the marital relation and the legal rights of each of the parties in the property of the other, and it is executory with respect to the obligation of the husband to protect, support and maintain, and of the wife to love, cherish and obey according to the ritual. Contracts to give are usually enforcible only in certain rigidly defined cases; in England such contracts must be entered into by deed. Gifts and other contracts, the performance whereof is one-sided, are called unilateral.

Contracts may be considered as *principal* and *accessory*. Principal contracts may be subdivided, according to their objects, into classes as follows: (1) Alienatory, which includes, besides gifts, all agreements of barter and sale and conveyances of land; (2) permissive use, including loans and lettings for hire; (3) marriage; (4) service, a very large and most important class, including care-taking by depositories, warehousemen, etc., doing work on material, transportation, professional and domestic service, agency and partnership; (5) negative service, somewhat grudgingly recognized by law as interfering with freedom, and including contracts to withhold competition and other restraints of trade; (6) aleatory, which class includes bets and stakes, not enforced under modern legal systems; lotteries, tabooed in this and some other countries; wager contracts or stock jobbing — but it includes also annuities, bottomry, marine insurance and all other kinds

of insurance. Accessory contracts are those — like (1) suretyship; (2) indemnity; (3) pledge; (4) warranty; (5) ratification — which create rights intended to be merely auxiliary to other rights. A contract of suretyship must be in writing according to the Statute of Frauds. Contracts are discharged: (1) By mutual agreement; (2) by performance; (3) by merger in, or substitution of, another agreement, also called novation; (4) by operation of law, i.e., prescription, statutes of limitation or because of the disability or legal incapacity (through infancy, lunacy, coverture, etc.) of one or more of the contracting parties. The right of action on a contract is assignable but the assignment must be in writing. Generally speaking, simple contracts as opposed to «specialties» may be entirely informal, and need not be written down, either in whole or in part. The English 'Statute of Frauds' passed «for the prevention of many fraudulent practices, which are commonly endeavored to be upheld by perjury and subornation of perjury,» renders void any contract for the sale of goods for the price of £10 and upwards, unless there be a part delivery of the goods, or part payment of the price, or some note or memorandum in writing of the bargain made and signed by the parties or their agents. The same statute, though it does not avoid the contract, allows no action to be brought on it until it has been written down and signed: When it makes an executor personally liable; or guarantees the debt of another; or creates a liability in consideration of marriage; or relates to an interest in land; or is not to be performed within a year. Another later English statute requires that the reacknowledgment of a debt that has been barred by the statutes of limitation must also be written and signed. The provisions of the 'Statute of Frauds' have been adopted with variations in most of the States of the Union. A written memorandum signed by the parties or their agents is generally required in the cases following:

(1) Contracts by their terms not to be performed within a year from the making thereof. (2) A promise to answer for the debt, default or miscarriage of another person. (3) Contracts made in consideration of marriage, except mutual promises to marry. (4) Promise of an executor, or administrator, to pay debts of deceased out of his own property. (5) Contracts for the creation of any interest or estate in land, with the exception of leases for a short term, generally one year. (6) Contracts for the sale of goods above a certain value, unless a portion of the price is paid or part of the goods delivered. The required value of the goods sold varies in different States from $30 to $200. In a number of the States no such provision exists. (7) In many of the States declarations or conveyances of trust estates. (8) In many States representations as to the character, credit or responsibility of another person.

Partial performance of the contract is generally held to dispense with the necessity for a writing.

Freedom of Contract.— The clauses of the State bills of rights, which prohibit the impairment or deprivation of life, liberty or property without due process of law, serve as a protection to the right to make contracts respecting personal services or property; with reference to the exercise of Federal power this right is protected by the Fifth Amendment to the Constitution; while, as regards action by the States, Amendment XIV provides that «no State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any State deprive any person of life, liberty or property, without due process of law.» There are some limitations to the right to make contracts. The laws which define the competency of persons to make contracts determine the validity of contracts so made; thus, infants, lunatics and married women (to a limited degree) are regarded as incapable of entering into a legal contract, and the obligations assumed under contracts made by such persons, even though made voluntarily, are void or revocable. Contracts opposed to public policy or violating valid legislative restrictions or prohibitions cannot be enforced, nor do the constitutional provisions extend protection to the obligations of such contracts. The valid exercise of the police power of the State may necessitate the imposition of certain restrictions on private rights, but such restrictions on the freedom of contracts do not impair the constitutional guaranties. Statutes may be passed in the public interest to regulate the sanitary conditions under which persons labor or to restrict the working hours of certain classes of laborers, such as women and children, and any contract made in violation of such prohibitions is invalid, since to this extent the State reserves the right to restrict the freedom of individuals to make contracts. By statutory provisions also the State may restrict the power of those in public employment to limit their obligations in this respect.

Impairment of Contracts.—Article I, section X, paragraph 1 of the Constitution provided that no State «shall pass any law impairing the obligation of contracts,» and most of the State constitutions contain a similar limitation. But there is a distinction between contractual obligations and those that are not contractual which may be determined by the ordinary legal rules defining the validity of contracts. The right to hold public office and the privilege of the elective franchise are not contractual obligations, and may be changed by subsequent legislation. Marriage and the inchoate rights of property existing in either party by virtue of marriage are subject to retrospective legislation. The constitutional prohibition applies not only to private contracts but to contracts made by a State or under its authority, wherefore no State by legislation may impair the obligations of its contracts. But the power to legislate on a subject may not be contracted away since one legislature may not bind a succeeding legislature with regard to matters coming within the scope of general legislative power, though in some cases a grant of certain rights or privileges may be deemed irrepealable. Thus, holders of bank notes issued under State authority or holders of State bonds which by statute have been declared receivable in payment of public taxes are protected by constitutional provision against infringement of their rights through subsequent legislation which aims to modify or repeal the statute conferring such rights. The further issue of such notes or bonds might be prohibited, but those who have acquired them while

the statute was in force are possessed of so-called vested rights. Private individuals may not sue a State on its obligations. Charters granted to private corporations are contracts and, unless the right to alter, amend or repeal has been reserved to the State, the benefits accruing from such charters cannot be withdrawn or impaired by subsequent legislation (see DARTMOUTH COLLEGE CASE), though most States have constitutional or statutory provisions limiting the protection against subsequent legislation usually afforded to such charters by their status as contractual obligations. The charters of public corporations may not be considered as contracts, and, being in the nature of legislation, are subject to modification or repeal at the legislative will, if no individual interests have been vested under them. McClain says that, in general, subsequent remedial legislation changing the general law relating to procedure does not impair the obligation of contracts already made; but if a contracting party be deprived by statute of any substantial relief for breach of contract by the other party, then such statute constitutes an impairment of the obligations of the contract and to that extent is prohibited. Hence, while the period of limitation within which actions on contracts may be brought is subject to the legislative change, such change cannot be applied to existing contracts if the parties thereto be deprived of a reasonable time within which to bring action for enforcing their rights under their contracts.

CONTRACT BRIDGE. See BRIDGE.

CONTRACT LABOR. Previous to 1885, when on 26 February the Contract Labor Law was passed by Congress, employers of large bodies of laborers were accustomed to arrange with their agents abroad for the shipment to this country of large numbers of an ignorant, servile class of foreign laborers—a practice that had a most disastrous effect upon home labor. These «assisted immigrants» reduced our labor market to a level with themselves, for not only was their passage-money paid, but they were bound by an agreement to work for a specified time at wages below those paid to resident laborers. A remedy for these evils was sought in the passage of the act above mentioned, which had a three-fold design, viz.: (1) to protect the interests of our own laboring classes; (2) to raise the standard of foreign immigrants; and (3) to check the immigration to this country of those who were unable to pay their own passage.

The main provisions of the Act are as follows:—

First. «The prepayment of transportation, or the assistance or encouragement of migration of aliens or foreigners under contract to labor in the United States, is unlawful.»

Second. «Such contracts made previous to their migration are void.»

Third. «Every person or corporation guilty of unlawfully assisting or encouraging the immigration of such laborers is subject to a penalty.»

Fourth. «The master of any vessel knowingly bringing such laborers into the country is to be decreed guilty of a misdemeanor.»

Various amendments have been added to the original act, providing for the proper inspection of vessels to ascertain violations of the law, if any; to prevent the landing of aliens that come within the prohibitions of the Act, or their deportation, if landed; forbidding the soliciting of immigration abroad by promises of employment in this country; and extending the penalties for violation of the Act so as to include any who may assist in bringing in prohibited aliens. On 3 March 1903, the prohibitions contained in the above act were extended to all forms of implied contracts, and made to cover labor or service of any kind, whether skilled or unskilled.

The Contract Labor Law and its supplementary legislation have been declared constitutional under the clause giving to Congress the power «to regulate commerce with foreign nations»; but the statute has been held by the United States Supreme Court to be directed only against the importation of unskilled cheap labor and to be applied solely to the «assisted immigrant brought into the country under contract to perform manual labor or service.» It is held, therefore, by amendatory legislation since 1885, that domestic servants, actors, artists, lecturers, singers, ministers, professors and members of a family or relatives of residents not of certain other excluded classes, as persons insane, diseased, convicts, or paupers, shall be exempt from the prohibitory provisions of the Act, and are entitled to admission.

The above laws have failed, however, fully to protect immigrants from southern Europe against the labor contractors known as padrones, who, taking advantage of the immigrants' ignorance of our language and customs, have gained control of laborers of their own race and often make large fortunes by furnishing these laborers to American employers. Consult United

States Immigration Commission, 'Immigration Legislation' (1912).

CONTRACT NOTES, the same as bought and sold notes (q.v.).

CONTRACT SURGEONS. By virtue of the act of 2 Feb. 1901, the Surgeon-General of the United States Army, with the approval of the Secretary of War, may appoint as many civilian physicians as may be necessary as contract surgeons, at a compensation not greater than $150 per month. Contracts may be general or special. Special contracts do not require travel or the giving up of private practice, and are for medical services at arsenals and similar places, where the amount of work does not justify the appointment of a medical officer. A general contract obligates the surgeon to take station and change station as ordered. He receives pay as stipulated in the contract and the allowances of a first lieutenant. Contract surgeons on general duty for more than three months must pass an examination like that for admission to the Medical Reserve Corps. Contract surgeons have a similar degree of authority over Hospital Corps men to that of medical officers and are accorded the same respect. The policy of the Army at present is against the appointment of contract surgeons on general duty, and reserve medical officers are now taking their place in increasing the military medical establishment. Formerly the Army employed dentists known as contract dental surgeons; these are now known as acting dental surgeons. See DENTAL CORPS.

CONTRACTILITY. See MUSCLES.

CONTRACTIONS, abbreviations employed with the view of saving labor in writing, and also in former times with the view of saving parchment in extending MS. copies of works and deeds. See ABBREVIATIONS.

CONTRAST. A term employed in psychology to denote an enhancement of a sensory experience which is induced by another sensory experience of the same modality. Contrast is alleged by some psychologists to occur also in feeling, and the term is occasionally loosely employed as a principle of explanation of certain spatial perceptions.

The contrast-effect may be successive or simultaneous. In successive contrast the inducing precedes the induced sensation in time. For example, an orange is more sour after dessert than before, the odor of Bordeaux is stronger following the scent of cheese, a surf of constant temperature seems warm on a cold day and cold on a warm day, a room of medium illumination seems light on emerging from a dark room, and dark on entering from the bright out-of-doors. In simultaneous contrast, on the other hand, the effect is induced simultaneously and it is reciprocal with the inducing sensation. If, for instance, a sub-liminal sweet is placed on one side and a supra-liminal salt on the other side of the tongue, then the sweet becomes liminal and the salt is enhanced. The best known instances of simultaneous contrast occur, however, in the field of vision. If from the same sheet of gray paper two narrow strips are cut and placed the one on a black, the other on a white background, then the former will appear much lighter and the latter much darker than the gray sheet (brightness-contrast). If, again, the same gray strips are placed the one on a well-saturated blue, the other on a good red background, and a sheet of tissue paper laid over all, then the former strip will be seen as yellow of poor chroma, the latter as a washed-out green (color-contrast). Vivid effects of color-contrast may also be seen in shadows, as, for example, the purple or violet shadows on the sun-lit snow. The results of the experimental investigation of color-contrast have been formulated in the following laws: (1) The contrast-effect is always in the direction of the complementary color; blue induces yellow, red induces blue-green, black induces white. (2) Color-contrast is greatest when brightness-contrast has been eliminated. (3) The nearer together the contrasting surfaces, the greater is the contrast-effect. (4) The elimination of contours enhances the contrast-effect. (5) The more saturated the inducing color, the greater is the contrast-effect.

Two types of theory have been offered in explanation of contrast, the one physiological, the other «psychological.» Physiologically regarded, it may be said in general that successive contrast is the result of adaptation to the inducing stimulus; an orange is more sour after dessert because the taste bulbs having become adapted to sweet respond without compensation to sour. In smell, the odors which contrast are antagonistic so that adaptation to the one leaves the other as it were in bolder relief. In temperature, adaptation to an aerial cold seems to have correlated with it a «tuning» of the sense organs of warmth (in the area concerned) so that they respond to a stimulus of lower temperature; in the same way cold spots are «tuned» to a higher temperature of stimulus with adaptation to warmth. In vision, adaptation together with the negative after-image is sufficient to explain most cases of successive contrast. Adaptation fails, however, to explain cases of simultaneous contrast; the effect of adaptation always requires an interval of time, whereas simultaneous contrast is immediate. The case of the sub-liminal sweet noted above may ultimately be explained by the fact that the sensory nerves connected with the taste bulbs radiate to the two sides of the tongue; in the present state of our knowledge we can only guess that closely related areas of the cortex are thereby stimulated, and that attention to the sour facilitates the simultaneous arousal of the sweet. Simultaneous brightness and color-contrast has been most satisfactorily explained by Hering. This author supposes that the stimulation of a portion of the retina which involves an assimilation (or dissimilation) of a photo-chemical substance carries with it a simultaneous dissimilation (or assimilation) of the same substance in the contiguous unstimulated portion of the retina.

There are two «psychological» theories of importance. Helmholtz explained contrast as a deception of judgment. If, for instance, a gray strip on a green background appears reddish, it is because it is seen as if through a green haze and the mind unconsciously infers that if the strip is gray it must appear reddish in order to compensate for the green. Except for an occasional text-book of physiology this theory has long since been given up; experiments may be devised which preclude the possibility of inference, and, furthermore, no explanation in

terms of the unconscious is satisfactory to science. Wundt, in his early books, brought contrast phenomena under his theory of relativity. (See WEBER'S LAW). He supposes that the effect results from the fact that we apperceive all sensory and affective experiences in relation to each other. As against this theory James has pointed out that the contrast-effect is directly experienced, and it cannot by any logic be made to depend upon an act of apperception. Wundt, however, now recognizes the physiological condition of contrast as a secondary principle of explanation.

The occurrence of contrast phenomena in feeling is doubtful. The opposition of affective qualities is not, as some authors assume, like that of color qualities. Pleasantness and unpleasantness are opposites in the sense that they are mutually exclusive. A decrease of the one, therefore, does not mean an increase of the other, i.e., the change is in the direction of indifference, of no feeling at all. It is true that pleasantness and unpleasantness are logically opposed, but there is no experimental evidence of an enhancement of the one by the previous experience of the other.

In space perception the size of objects and length of lines often seem larger or smaller, longer or shorter by virtue of the presence of objects or lines whose size or length is logically opposed. The illusion is not due to a contrast-effect as is often alleged, but to some brain-habit or disposition which conditions the perception.

Professor of Psychology, Cornell University.

CONTRAT SOCIAL, kôn'trä' sō'sē-äl', a work by Jean Jacques Rousseau (q.v.), embodying his political ideas and defending the sovereignty of the people. It was published in 1762 and was one of the powerful influences affecting the leaders of the Revolution.

CONTRAVENTION, in French law, an act done in violation of a legal obligation or condition. It is most frequently applied in Scottish law to any act done by an heir of entail in opposition to the deed of entail, or to the action founded on a breach of law-burrows.

CONTRAYERVA, kōn-trą-yėr'vą (Span. *contrayerba,* counter herb), the aromatic bitterish rootstock of *Dorstenia contrayerva,* a plant imported from tropical America, and used as a stimulant and tonic. The drug was once in much repute in low fevers, and was considered efficacious against snake-bites whence the name. See DORSTENIA.

CONTRERAS, kōn-trā'räs, Hernando de, Spanish adventurer: b. Spain about 1520; d. Panama May 1550. He was the son of Rodrigo de Contreras (q.v.), governor of Nicaragua. After the fall of his father, and the confiscation of his property, Hernando and his brother, Pedro, with a number of dissatisfied officers, arranged a plot to seize Peru and Panama, which the brothers claimed as inheritors of the estate of their grandfather, Pedrarias. Hernando was to be king of the new realm, but was never proclaimed, as the failure of his attempt within two months made such a course impossible. Panama was captured 20 April 1550, after several Church dignitaries had been slain, and a large part of the royal treasure stored in the city was taken. Hernando took a considerable part of his force to pursue one of the royal officers, leaving Pedro in command at Panama. The citizens improved the opportunity to retake the city, and Hernando was drowned shortly afterward. The other brother was never again heard of.

CONTRERAS, Juan Senen de, Spanish general: b. Madrid 1760; d. there 1826. He entered the Spanish army in youth, in 1778 took an active part in the Austrian campaign against the Turks, and in 1795 commanded in the War of Independence. While captain-general he gallantly but unsuccessfully defended Tarragona and was captured by the French. He was imprisoned in the castle of Bouillon on the Belgian frontier, but escaped in 1812, and two years later returned to Spain. His narrative of the siege of Tarragona formed the third volume of 'Mémoires relatifs aux révolutions de France et d'Espagne' (1825).

CONTRERAS, Rodrigo de, Spanish cavalier: b. Segovia, Spain, about 1495; d. Peru sometime after 1557; the last date when he was known to be living. He was appointed governor of Nicaragua in 1531, and sent an expedition into the interior, which discovered and explored Lake Nicaragua. The expedition had trouble with the adventurer, Robles, who tried to seize the newly discovered country, but was defeated. The administration of Contreras was turbulent and marked by constant disputes with the royal authorities and the dignitaries of the Church. Finally he was formally charged with various crimes and misdemeanors, found guilty, driven from the country, and all his property confiscated (1549). He vainly sought redress from the Spanish government, and finally returned to America, going to Peru, where he was not heard of after 1557. For the attempt of his sons to avenge their father's alleged wrongs, see CONTRERAS, HERNANDO DE.

CONTRERAS, Mexico, village about 12 miles southwest of the city of Mexico, the scene, 19–20 Aug. 1847, during the Mexican War, of an important battle between a Mexican force of 7,000 under General Valencia, supported by another of 12,000 under General Santa Anna, and a United States force of 4,500 under General Scott. The Mexicans occupied a strong position on high ground and fought for a time with great gallantry, but, being attacked both in front and rear at daylight on the 20th, finally gave way and fled in confusion, after having lost in killed and captured over 1,500.

CONTRERAS, Battle of (Mexican name, *Padierna*), in the Mexican War, 20 Aug. 1847. At Churubusco (q.v.), the main road south from the city of Mexico is joined from the southwest by another, running to the hills beyond the hamlet of Contreras. This is about 12 miles from the city; a mile nearer the latter is the hamlet of Padierna. The road to Mexico City winds around the east flank of the ridge,

across the brook from Padierna and keeps on north, across four brooks to the important village of San Angel. The Mexican general, Valencia, with the "Veterans of the North," forming the right of Santa Anna's army, had made his headquarters at San Angel on the 17th; and he decided to occupy and fortify Pelón Cuauhtitlan, two miles southwest, to block the road to the capital skirting it. Powerful batteries were placed to command this and sweep the pedregal; and some 7,000 men were concentrated about the ridge, and facing Auzaldo and San Geronimo. Santa Anna, apprehensive for his position on the main road, ordered Valencia to retire to Churubusco; but Valencia refused. On the 19th, Scott, at San Augustin, ordered a road leveled to Padierna; Twiggs and Pillow to check the enemy meanwhile. A fierce running fight with the Mexican troops ensued, and skirmishing continued. At 2.30 A.M. of the 20th, a dismal morning of cold, rain and fog, Smith and Riley moved southwest through the steep, gullied, slippery streets of San Geronimo, and, unperceived, gained positions southwest of the ridge on the right flank of Valencia's lines. Meantime a strong diversion was made by an assault on Padierna and along the rocks. The battle was won by a single impetuous onslaught of Riley's troops against Valencia's main batteries on the ridge, when the "Veterans of the North" broke and scattered like sheep. The battle was over in 17 minutes, and the Mexican army a routed mob, in face of a force numbering but a fraction of their own. Shields, who had taken Smith's place at San Geronimo, marched rapidly to Auzaldo to cut off the retreat; but a portion of the army escaped in wild flight toward Churubusco along the San Angel road, while the rest plunged in disorder down the steep flanks of San Geronimo, leaving all impediments behind. No more brilliant victory was won in the war. Scott had not over 4,500 men in sight, to Valencia's 7,000, and Santa Anna's 12,000 within supporting distance; and the natural and artificial defenses should have made the Mexican positions impregnable. The latter lost 700 killed and wounded, and 813 prisoners, including 88 officers, four of them generals; 22 brass cannon, vast quantities of small arms and ammunition, and many hundreds of pack-mules and horses. The American loss was 60 killed and wounded. This route contributed materially to the winning of Churubusco. Consult Wilcox, 'History of the Mexican War'; Wright, 'Life of Scott'; Scott, 'Autobiography.'

CONTRIBUTION, in law, the right of one person to exact from another his pro rata share of a common loss, as where one of two sureties discharges the entire obligation, he is entitled to secure from his cosurety his share of the amount. (See INDEMNITY; PRINCIPAL AND AGENT). In the law of war, contribution denotes the levy of money or supplies imposed by an invader upon the citizens of the territory occupied. See CONQUEST, RIGHT OF; TAXATION; TRIBUTE; WAR, and consult the authorities referred to under the last named.

CONTUMACY, kŏn'tū-ma-sĭ, the offense of refusal or neglect of a party accused to appear or answer to a charge preferred against him in a court of justice, chiefly known in countries on the European continent. *Actual* contumacy is the refusal of a party actually before the court to obey some order of the court. *Presumed* contumacy is the act of refusing or declining to appear upon being cited. In civil causes a person in such case may be properly made liable to a decision against him for his neglect in not appearing to defend his rights; but by an extension of the principle to criminal cases persons are often sentenced, in their absence, to punishment *in contumaciam*, i.e., they are regarded as charged with the offense, but not convicted thereof.

CONTUSIONS, lesions of the body resulting from a blow struck by a blunt instrument without breaking of the skin or fracture of a bone. Contusions may involve the skin alone, or may produce some change in the deeper tissues. In contusions there is, as a rule, some rupture of blood vessels. This results in the extravasation of blood, which, if small in amount, causes minute spots called petechiæ. When elongated in stripes such hæmorrhages are called vibices; or, when irregular and small, ecchymoses. When the hæmorrhage is large and collected in one place, they are termed hæmatonata. Contusions, if very severe, may result in gangrene, hence all large contusions need prompt medical attendance, but small contusions may be treated with hot water in which there is some antiseptic, as a one-per-cent solution of carbolic acid; and if carefully bandaged and kept from being infected, they usually recover quickly.

CONUS, a genus of gasteropodous mollusks, the type of the family *Conidæ* or cone-shells, so named from the form of the shell. They are found in the southern and tropical seas. The genus comprises several hundred species, some of them having very beautifully colored shells which are much prized by collectors. The rarest and finest of these is *C. gloria-maris.* All have a short, strong foot bearing a water-pore, two tentacles with eyes set on the outside at the centre and a long siphon. They live in holes in rocks and in the clefts of coral-reefs, and their food consists mainly of other mollusks. Some of the species have a poisonous bite.

CONVALLARIA, the lily-of-the-valley, the typical genus of the tribe *Convallariinæ* of the *Liliaceæ,* or lily family. The order has about 23 genera, and 215 species, widely distributed. Nine of the genera are found in the American flora, among them: *Asparagus, Clintonia, Polygonatum convallaria* and *Trillium.* See LILY-OF-THE-VALLEY.

CONVECTION OF HEAT. See HEAT.

CONVENT (Lat. *conventus*), primarily the community of monks or nuns occupying a monastery, priory or other establishment of a monastic or semi-monastic character. But the word is generally used to designate rather the establishment itself, if it is simply a cloister and not a considerable monastery or an abbey. The parts of a properly equipped conventual establishment are the church or chapel, including the choir, namely, that portion of the church in which the members assemble to recite or chant the psalms, etc., of the canonical hours; the chapter-house, an apartment in which the inmates assemble to deliberate or discuss com-

munity affairs; the cells, or separate quarters of the inmates; the refectory or dining-hall; the dormitory; the infirmary; the parlor for reception of visitors; the library; the treasury; the cloister, an enclosed space for recreation; and the crypt, the convent's place of burial. The word «cloister» is also used in the sense of convent: in that use cloister signifies a religious house access to which is restricted by the laws of the Church. In its popular sense the word is applied to an establishment containing a sodality of nuns, the male religious being denominated monks and their establishments monasteries. Convents are generally classed as strictly enclosed and unenclosed, but these divisions often overlap in function and are not mutually exclusive. The former represent the older type of convents to which women were attracted by a desire to save their own souls and those of others by prayer, seclusion and mortification, while the latter refers to those which are devoted to active work along educational or social lines for the relief of others. Routine is prescribed; the bishop of the diocese has the inspection of the convent under his charge. In most orders the nuns are divided into choir sisters, who have religious duties only, and lay sisters who perform the manual labor of the convent. The first convent in England was erected at Folkestone in 630. The history of European convents follows the history of the monasteries. Consult Hélyot, 'Histoire des ordres religieux' (Paris 1792); Eckenstein, 'Woman under Monasticism' (Cambridge 1896); Steele, 'The Convents of Great Britain' (London 1902).

CONVENTICLE, a private assembly or meeting for the exercise of religion. The name was at first given to the private religious meetings of the early Church and then to a cabal of monks for the purpose of securing the election of a favorite as abbot. It was next applied as a term of reproach to the religious assemblies of Wickliffe, the meetings of the English and Scottish nonconformists, and afterward applied to meetings of petty sects and dissenters generally. In strict propriety the word denotes an unlawful assembly, and cannot therefore be justly applied to the legal assembling of persons in places of worship licensed according to law. The Conventicle Act of 1664 outlawed all assemblies for religious purposes other than those of the Church of England. The penalty for repeated offenses was transportation.

CONVENTION, Political, an assemblage of delegates representing the members of a political party, whose leading function is to nominate the candidates of that party for elective offices. In the early years of the nation candidates were often nominated at mass meetings, but the growth of the country necessitated a change. Delegates were appointed by the local caucuses to confer with delegates from other caucuses in the city, county or district, with the object of making nominations for the next larger area. This method quickly gained favor and early in the 19th century Pennsylvania adopted the county convention and Massachusetts and other States both the county and Congressional conventions. The legislative caucus performed the functions of the State convention for many years because of the difficulties of travel and communication over so large an area; the legislative caucus method also was used in the nomination of national candidates, and, as the Congressional caucus, was used for more than 25 years to choose the party candidates for President and Vice-President. During the campaigns of 1824 and 1828, owing to the failure of the Congressional nominating caucus, the factions of the Democratic-Republican party held nominating conventions that were neither national nor systematically representative, and the first nominating convention that can be called national was held at Baltimore in 1831 by the Anti-Masonic party. Since that time the system has gradually developed into the present complicated but well-ordered system.

Minor Conventions.—First in order of the nominating conventions is the local primary, caucus or primary convention, called together by the primary committee, and consisting of those voters affiliated with the party who reside in ward, precinct or township. This primary makes nominations to local offices and selects delegates to the nominating convention of the county or district. The county convention nominates candidates to county offices and sends delegates from among its members to a district convention which selects candidates for Congress and elects delegates to the State convention. In some States delegates to both district and State conventions are elected by the town primaries. The State convention nominates candidates for State offices and sends delegates-at-large to the national convention. In the Democratic party the State convention may select all the delegates and instruct them. The State convention formulates party policy within the State and decides questions of party regularity, though appeal may be made to the national convention. The basis of representation in the State convention is the party vote at the preceding election — whether Presidential or gubernatorial, whereas the membership of the national convention is not concerned with party strength.

Party Committees.—In early times the convention concerned itself only with the immediately succeeding campaign; it had a chairman, secretary, treasurer and other necessary officers, but the organization was purely temporary and had no permanency; on adjournment the organization lost its existence, and the next convention might be called either by the officers of the previous convention or by an informal self-appointed committee. Hence conventions adopted the plan of appointing permanent committees to act in their behalf during the interval between conventions. The Democratic convention of 1848 was the first to appoint a national committee but the committee's value was not generally recognized until after the Civil War. The national committee is now composed of one member from each State and Territory (chosen for four years or until the next national convention) and though subordinate to the convention exercises great authority — often possessing sufficient power and influence to control the convention and dominate its policies. It decides the place of meeting, arranges the seating of delegates, and, most important of all, selects the temporary chairman of the convention, who sounds the keynote of the campaign. It has then per-

formed its duties and on the opening of the convention is dissolved to make way for the appointment of a new committee, the members of which are in harmony with the Presidential candidate. The chairman of the national committee, chosen by the President, who is the nominal head of his party, is both nominally and actually the head of the organization and is in close touch with the candidates. When the convention closes the new national committee organizes at once and is usually divided into subcommittees, such as the executive committee, the finance committee, the committee on bureau of speakers, the committee on publicity to supervise the literature, press matter and distribution of public documents. Though not organically connected with State and local committees, the national committee in effect, through its State member, directs the campaign in every minor division. There is also the national Congressional committee, the organization of which differs in the two largest parties. The Republican committee consists of one member from each State and Territory represented in Congress (provided that State has a representative in Congress) chosen in a joint caucus of the members of both Houses. The Democratic committee is chosen at separate caucuses of the two Houses, nine members being appointed by the Senate and one member being appointed for each State and Territory represented in Congress. If a State has no Democratic representative in Congress, a prominent Democrat of that commonwealth is appointed to the committee. The Congressional committees have charge of the mid-term elections when the two parties endeavor to elect a majority in Congress either as an endorsement or a condemnation of the party which has previously elected the President. Subordinate to the national committees are the State central or State executive committees, varying in their machinery according to the section of the country. Outside of New England, where the town committee holds the most important place, the county committee is almost universally the important one, but no district is too small to be used as a basis for party work, the Congressional, senatorial, judicial and school districts, and the city wards or precincts all having their share in the party organization. The State executive committee (comprising as few as 13 members, as in Indiana, or more than 100 members, as in Pennsylvania) may be named by the chief candidates of the party or may consist of representatives of Congressional or State senatorial districts and of counties.

The National Convention.—Both national conventions are composed of two delegates from each Congressional district and four delegates-at-large from each State. Thus a national convention contains twice as many delegates as there are members of the House and Senate combined. Both the largest parties admit delegates from the Territories, varying as to numbers and privileges of voting. The State organization determines the method of electing delegates to national conventions but the Republicans prescribe that delegates shall be chosen in the same way that Congressmen from the same districts are nominated—either at primary elections or district conventions. The Democratic delegates may be selected by the State convention as a whole, by the delegates of each individual district or by each district at a district convention. Having assembled, the convention at its first session accepts the temporary officers nominated by the national committee and upon the roll call by the temporary chairman, the delegates of each State and Territory select one of their number as a member of each of the four most important convention committees, by whom the permanent organization of the convention is effected. At the next session, on the acceptance of the report of the committee on credentials, the permanent chairman, vice-presidents and other officials are elected and the rules adopted, usually as suggested by the committee on rules and order of business. Democratic national conventions to 1936 always required a two-thirds vote for the nomination of President or Vice-President, but all other parties now require only a simple majority. The Democrats also employ the «unit rule,» under which a majority of the delegates from a State may cast the entire vote of the State even over the protest of the minority, whereas the Republicans allow delegates to vote as individuals even though the State convention may have instructed the delegation to vote as a unit. The rules having been adopted, the committee on resolutions then presents the platform which may or may not be amended by the convention before acceptance. The nomination of candidates is the next and most important business, the roll being called by States in alphabetical order, whereupon the delegates selected to place the candidates in nomination make their formal speeches. The balloting continues until one candidate receives the vote required to nominate, several days being consumed sometimes in reaching an agreement. Having completed the most important task for which they assembled, the delegates finish the work of the convention by electing a new national committee which, as previously stated, takes full charge of the campaign and remains in office until the next national convention has assembled. The direct primary (q.v.) has done much to rid the political parties of the obnoxious «boss» system by making the nominations more truly representative of the body of the voters. It has shown also that the convention system is not a necessity but is mainly useful for the formulation and promulgation of party principles.

CONVENTION OF 1787. See CONSTITUTION, FRAMING OF THE.

CONVENTIONS, Constitutional, in the United States. Conventions for the purpose of framing constitutions originated in the United States during the early years of the Revolution (1774–76) and the development of the methods employed may be divided into three phases: first, the framing of constitutions by the regular legislative bodies under direct authorization of the people; second, the performance of that function by a body separate and distinct from the regular legislature; and third, the submission of the proposed constitutions to popular approval before they become effective. The colonial legislative assemblies actively participated in the movement leading up to the Revolution; but as the royal governors (save in Rhode Island, Connecticut, Delaware and Pennsylvania) could adjourn, prorogue or dissolve these bodies, their replacement became necessary when the period of military opposition arrived. Hence provincial congresses or conventions sprang into existence during 1774–75, but as these were only temporary organizations, Continental Congress recommended to New Hampshire (3 Nov. 1775) and to South Carolina (10 May 1776) that the people select representatives, who, if they deemed necessary, should establish a form of government to continue during the dispute with the mother country. Under this recommendation a number of constitutions were framed during 1776 to 1778. In eight instances (North and South Carolina, Georgia, Virginia, New Jersey and the continuation of the charters in Massachusetts, Rhode Island and Connecticut) the constitutions were adopted and promulgated by the legislative bodies without previous authority from or ratification by the people. In New Hampshire and Delaware in 1776, and in Georgia, New York and Vermont in 1777, the legislative bodies had been expressly authorized by popular vote to take such action, but the instruments enacted were not in any way submitted to the people. In Maryland, Pennsylvania and North Carolina in 1776, and in South Carolina in 1778, the legislatures which framed the constitutions received express authority from the people, and some time before enactment, copies were distributed so that the people might have an opportunity to object and suggest changes.

The principle that popular authority should be given before a constitution could be framed seems to have been well established and the feeling prevailed too that no constitution should be adopted until submitted to and approved by the people. Some of the first constitutions were informally submitted (Pennsylvania, Maryland, North and South Carolina), but the first instrument of government formally subjected to a referendum was the proposed Massachusetts constitution of 1778. The first constitutions framed by bodies separate and distinct from the regular legislatures — and the only ones so framed during the Revolutionary period — were those of New Hampshire and Massachusetts. In the former colony delegates were selected in 1778 and drafted a constitution in 1779, but on submission to the people it was rejected, as were two constitutions proposed by the second convention in 1781 and 1782, but the third constitution submitted by the second convention in 1783 was adopted. In 1777 a majority of the Massachusetts towns authorized the formation of a constitution by the general court, but the proposed instrument was rejected in 1778, largely because it had not been framed by a body appointed for that special purpose. Accordingly, a distinct convention was assembled and the constitution drafted by it was accepted in 1780.

Since 1784, with a few exceptions, constitutions have been framed or adopted by conventions chosen by the people for this special purpose. The Nebraska constitution of 1866, however, was framed by the territorial legislature and submitted to the people by that body. In Michigan the legislature provided for a special commission to prepare a new constitution but in 1874, when the instrument as drafted was submitted to popular vote, it was rejected. In Rhode Island a constitution was prepared in a similar manner but it was rejected in 1898 and 1899. In 1911 the Indiana legislature drafted a new constitution but the courts enjoined the legislature from submitting it to the people. Though more than 200 conventions have been held not all have framed constitutions; the Massachusetts constitution of 1780 remained practically unchanged until the revision of 1917–18, though conventions were held in 1820–21 and 1853. Some States hold constitutional conventions more frequently than others; Virginia has held conventions in 1776, 1829–30, 1850–51, 1861, 1864, 1867–68 and 1901–02; and in 1776–77, 1801, 1821, 1846, 1867–68, 1894, 1915 and 1938 similar bodies met in New York; but in Minnesota no convention has assembled since the constitution was framed in 1857, and only two have been held in Indiana (1816, and 1850–51). The number of conventions in the Southern States is relatively larger owing to the secession conventions and the two sets of conventions called in these States during the Reconstruction period. For the history and characteristics of the State constitutions see UNITED STATES — THE FORMATION OF STATE CONSTITUTIONS; UNITED STATES — STATE CONSTITUTIONS OF THE; CONSTITUTION, FRAMING OF THE; CONSTITUTION OF THE UNITED STATES; CONSTITUTIONAL AMENDMENTS, HISTORY OF; UNITED STATES — THE FEDERAL CONVENTION OF 1787.

Constitutional conventions have been held in the various States in the following years, most of the instruments framed being adopted the same or the succeeding year, but in some cases constitutions were framed by bodies other than regularly constituted conventions (the words "not submitted" meaning that the constitution was put into operation without first submitting it to popular vote):

ALABAMA: 1819; 1861 (not submitted; secession convention); 1865 (not submitted; Reconstruction convention); 1867; 1875; 1901.
ARIZONA: 1910.
ARKANSAS: 1836 (not submitted); 1861 (not submitted; secession convention); 1864 (not submitted; Reconstruction convention); 1864; 1868; 1874; 1918 (rejected).
CALIFORNIA: 1849; 1878–79.
COLORADO: 1864 (rejected); 1865 (ratified but State not admitted); 1875–76.
CONNECTICUT: Operated under colonial charter of 1662 until many years after Revolution; 1818.
DELAWARE: 1776 (not submitted); 1792 (not submitted); 1831 (not submitted); 1852–53 (rejected); 1897.
FLORIDA: 1838–39 (not submitted); 1861 (not submitted; secession convention); 1865 (not submitted; Reconstruction convention); 1868; 1885.

GEORGIA: 1776 (temporary constitution proclaimed by Provincial Congress); 1776–77 (not submitted); 1788; 1789 (not submitted); 1795 (amendments, not submitted); 1798 (not submitted); 1833 (amendments, rejected); 1838; 1839 (amendments, rejected); 1861 (not submitted; secession convention); 1865 (not submitted; Reconstruction convention); 1867–68; 1877.
IDAHO: 1889.
ILLINOIS: 1818 (not submitted); 1847; 1862 (rejected); 1869–70; 1922 (rejected).
INDIANA: 1816 (not submitted); 1850–51 (revised in 1911 by legislature but injunction issued against its submission to people).
IOWA: 1844 (rejected); 1846; 1857 (Amendments of 1900 were held to be unconstitutionally proposed and adopted).
KANSAS: 1855 (Topeka Convention); 1857 (Lecompton Convention); 1858 (Mineola-Leavenworth Convention); 1859 (Wyandotte Convention; constitution ratified 1859, effective 1861).
KENTUCKY: 1792 (not submitted); 1799 (not submitted); 1849–50 (not submitted); 1890 (constitution was changed by convention after its approval by people).
LOUISIANA: 1811–12; 1844–45; 1852; 1861 (not submitted; secession convention); 1864 (Reconstruction convention; government organized under this constitution not recognized by Congress); 1867–68; 1879; 1898; 1913; 1921.
MAINE: 1819.
MARYLAND: 1776 (not submitted); 1850–51; 1864; 1867.
MASSACHUSETTS: 1777–78 (rejected, wherefore the State lived under its colonial charter until 1780); 1779–80; 1820–21 (amendments); 1853 (rejected).
MICHIGAN: 1835; 1850; 1867 (rejected); 1873 (revision by a commission rejected in 1874); 1907–08 (revised).
MINNESOTA: 1857.
MISSISSIPPI: 1817; 1832; 1861 (not submitted; secession convention); 1865 (not submitted; Reconstruction convention); 1868 (rejected in 1868 but adopted in 1869); 1890 (not submitted).
MISSOURI: 1820; 1845–46 (rejected); 1861–63 (not submitted, Union Convention); 1865; 1875.
MONTANA: 1889.
NEBRASKA: 1866 (drafted, accepted by Congress in 1867); 1875; 1919 (amendments; adopted 1920).
NEVADA: 1863 (rejected); 1864.
NEW HAMPSHIRE: 1775–76 (not submitted); 1778–79 (rejected); 1781; 1782 (rejected); 1783; 1791–92 (amended in 1851, 1876, 1889, 1902, 1912).
NEW JERSEY: 1776 (not submitted; Revolutionary Congress); 1844; constitutional commissions sat in 1873 and 1894.
NEW MEXICO: 1889–90 (rejected); 1910.
NEW YORK: 1776–77 (not submitted); 1801 (five amendments promulgated without submission); 1821; 1846; 1867–68 (rejected); 1894; 1915 (rejected); 1938.
NORTH CAROLINA: 1776 (not submitted); 1835 (amendments); 1861 (not submitted; secession convention); 1865 (not submitted; Reconstruction convention); 1866 convention reassembled, proposed amendments rejected); 1868; 1875 (amended).
NORTH DAKOTA: 1889.
OHIO: 1802; 1850–51; 1912 (revised).
OKLAHOMA: 1905 (convention proposes new State to be called Sequoyah); 1907.
OREGON: 1857.
PENNSYLVANIA: 1776 (not submitted; Revolutionary Congress); 1783–84 (council of censors met without action); 1789–90 (proclaimed without submission); 1837–38; 1872–73.
RHODE ISLAND: Operated under colonial charter of 1663 until 1842; 1824 (rejected); 1834 (abortive); 1841–42 (People's Convention); 1841–42 (charter government convention); 1842.
SOUTH CAROLINA: 1776 (not submitted; promulgated by Revolutionary convention); 1777–78 (put into effect by legislature without submission); 1790 (not submitted); 1860–61 (not submitted; secession convention); 1865 (not submitted; Reconstruction convention); 1868; 1895.
SOUTH DAKOTA: 1889.
TENNESSEE: In 1772 the Watauga Association adopted a constitution and in 1784 a constitution was put into operation in the State of Franklin but was not ratified at convention of 1785; 1796 (not submitted); 1834; 1861 (secession convention); 1865 (Reconstruction convention); 1870.
TEXAS: In 1827 a constitution was framed for Coahuila and Texas; in 1833 another was framed at San Felipe but never recognized by Mexico or put into operation; in 1835 a "Provisional Constitution" was framed; and in 1836 the constitution of the Republic of Texas; 1845; 1861 (secession convention); 1866 (Reconstruction convention); 1868; 1875.
UTAH: 1895.
VERMONT: 1777 (not submitted); 1786; 1793; 1799; 1806 and 1813 (meetings of council of censors, abortive); 1822 and 1828 (amendments referred to conventions by council of censors and all but one rejected); 1836; 1843; 1850; 1857; 1870; 1880 (amendments proposed by Senate, council of censors having been abolished and adopted by people in 1883); 1890, 1900, 1910 and 1913 (amendments submitted but only 10 adopted at elections).
VIRGINIA: 1776 (not submitted; Revolutionary convention meeting as a constitutional convention); 1829–30; 1850–51; 1861 (secession convention); 1861 (not submitted); 1864 (not submitted; Reconstruction convention); 1867–68; 1901–02.
WASHINGTON: 1889.
WEST VIRGINIA: 1861–62; 1872.
WISCONSIN: 1846 (rejected); 1847–48.
WYOMING: 1889.

Methods of Calling Conventions.— The only provisions for calling conventions to be found in the earlier State constitutions were contained in those of Pennsylvania (1776), Vermont (1777), Georgia (1777), Massachusetts (1778) and New Hampshire (1784). In Pennsylvania the people were to elect a council of censors every seventh year, on the consent of two-thirds of whom a convention might be called to amend such parts of the constitution as the council thought necessary, but any proposed amendments, additions or excisions should be promulgated "at least six months before the day appointed for the election of such convention, for the previous consideration of the people, that they may have an opportunity of instructing their delegates on the subject." Only one meeting of this council was held and in 1790, after the constitutional requirements had been ignored in calling the convention of 1789, the council was abolished. Vermont made the same provision but the members of the council of censors were to be elected in a different manner. The Vermont council had called several constitutional conventions before being abolished in 1870. The Georgia constitution of 1777 provided that the legislature should call a convention if petitioned to do so by a majority of the voters of a majority of the counties, but the petitions must specify the desired amendments and in calling the convention the legislature must do likewise. In Massachusetts the desirability of revising the constitution was to be voted upon in 1795 and if two-thirds of the votes cast favored such revision, the general court was to call a constitutional convention, but as the vote was adverse the State never afterward had a constitutional provision for calling conventions, though the State attorney-general contends that such a convention is not only legal but is expressly authorized by the State constitution (1917 Mass. House Doc. 1711, pp. 2–3). The New Hampshire constitution of 1784 provided for the calling of a convention within seven years upon a favorable popular vote and the constitution of 1792 contained a similar provision for a vote within each seven years thereafter. Seven of the Revolutionary constitutions which continued after 1784 made no provision for conventions and others recently adopted have omitted such provisions (Georgia, 1798; Connecticut, 1818; New York, 1822; Missouri, 1820; Rhode Island, 1842; Pennsylvania, 1790, 1838, 1873; Virginia, 1830, 1852, 1864; Vermont, 1870; Arkansas, 1868, 1874; Tennessee, 1834; Texas, 1868; Louisiana, 1845, 1851, 1864, 1868, 1879, 1898), though in States which possess no such constitutional authority it has been assumed that conventions may be called.

Of the State constitutions now in force, 12 (Massachusetts, Vermont, Connecticut, Rhode Island, New Jersey, Pennsylvania, Mississippi, Louisiana, Texas, Arkansas, Indiana, North

Dakota) make no provision whatever for calling conventions, but conventions may be called in these States by legislative action, and the legislature has power to determine whether the people shall have an opportunity to express their wishes by voting upon the subject. Judge Jameson calls attention to 27 conventions which have met without constitutional authority for their assembling (Arkansas, 1874; Connecticut, 1818; Georgia, 1833, 1839; Indiana, 1850; Louisiana, 1852, 1879; Massachusetts, 1853; Missouri, 1845, 1861, 1865; New Jersey, 1844; New York, 1801, 1821, 1846; North Carolina, 1835; Pennsylvania, 1837, 1872; Rhode Island, 1824, 1834, 1841, 1842; South Carolina, 1790; Tennessee, 1870; Texas, 1876; Virginia, 1829, 1850) and since he wrote there have been at least three cases of the same character — Mississippi in 1890, Louisiana in 1898 and Connecticut in 1902. To this list also should probably be added the conventions of Delaware, 1791 and 1852; Maryland, 1850; Massachusetts, 1820 and 1917–18; and Indiana, 1918. Under another class of constitutions, such as those of Maine and Georgia, the legislature is empowered to call conventions without first submitting to popular vote the question whether a convention shall be held. Among the conventions thus called were those of Connecticut (1818), Rhode Island (1824, 1834, 1841, 1842), New Jersey (1844), Missouri (1861, 1865), Arkansas (1874), North Carolina (1875), Louisiana (1879), Mississippi (1890) and the secession and reconstruction conventions. On the other hand, several legislatures, though bound by no constitutional provisions, submitted the question to the people; among such were the conventions of Massachusetts (1820, 1853), New York (1821, 1846), Virginia (1829, 1850), Maryland (1850), North Carolina (1835), Pennsylvania (1837, 1872), Missouri (1845), Louisiana (1852, 1898), Tennessee (1870), Texas (1875) and Connecticut (1902). A third plan, adopted by 32 States, requires popular approval before a convention can be called, but in 25 of these States (Alabama, California, Colorado, Delaware, Florida, Idaho, Illinois, Kansas, Kentucky, Minnesota, Missouri, Montana, Nebraska, Nevada, North Carolina, Oregon, South Carolina, South Dakota, Tennessee, Utah, Virginia, Washington, West Virginia, Wisconsin and Wyoming) the legislatures have the power to decide the proper time when the question of holding a convention shall be submitted to the people. Seven constitutions contain a provision that the question of calling a convention shall be voted upon by the people at regular intervals without reference to legislative action. New Hampshire requires a vote upon this question every 7 years; Iowa every 10 years; Michigan every 16 years; Maryland, New York and Ohio every 20 years; and Oklahoma at least once every 20 years, though the legislature has discretionary power to submit the question more frequently. The legislatures of Iowa, Michigan, New York and Ohio may submit to the people the question of holding a convention at other times than those above specified. In States where the initiative and referendum are in vogue the legislatures have lost a large part of their control over the calling of conventions, since the people themselves may initiate and adopt a measure providing for the holding of a convention. These provisions have been adopted in the following States: Oregon (1902), Oklahoma (1907), Missouri and Michigan (1908), Arkansas and Colorado (1910), Arizona and California (1911), Nevada, Nebraska and Ohio (1912) and North Dakota (1914), and in 1913 Michigan broadened and simplified the provision inserted by the convention of 1908. In Idaho, Maine, Montana, South Dakota, Utah and Washington also the people can initiate and adopt a measure providing for the holding of a convention and by referendum may veto any statute by which the legislature attempts to interfere with a convention.

In most cases legislative action is necessary after the people have voted in favor of a convention, since delegates must be elected and provision be made for the assembling of the convention, though in only eight States are such matters left entirely in the hands of the legislature; some of the constitutions expressly limit the number of delegates and regulate their appointment, method of election, etc. In Michigan, New York and Missouri, however, the convention assembles as a matter of course without legislative action, the constitutions themselves containing provisions respecting appointment and election of delegates and the assembling of the conventions. When Congress passes an act enabling a Territory to apply for admission as a State, such act contains a provision for the number and election of delegates to a convention for the purpose of framing the new State constitution. But if the Territorial legislature itself take the initiative in calling such a convention, with the ultimate object of applying for admission into the Union, provision for delegates, etc., is usually made by the Territorial legislative act. Respecting a national convention, Article V of the Constitution of the United States provides that "the Congress . . . on the application of the legislatures of two thirds of the several States, shall call a convention for proposing amendments," thus imposing on that body no restrictions as to the conditions under which the convention shall be held.

Procedure of Constitutional Conventions. — Conventions act under very few constitutional restrictions as regards their procedure, and in general have adopted their own rules, differing but slightly from those of other deliberative bodies. Though possible, few conventions attempt to perform their functions as a body, but usually divide the work among committees. The method of transacting business mainly in committee of the whole, with a few small committees to handle minor details, is apt to prove unsatisfactory unless the plan of the constitution be quite complete before the meeting of the convention. The Federal convention of 1787 used the committee of the whole to a large extent, as did also the Pennsylvania convention of 1789. Some of the earlier constitutions were framed by a small committee which had been given full power to prepare and report a draft of a constitution to the whole convention. This method was adopted by the Revolutionary conventions of Maryland, New Jersey, Pennsylvania and Virginia in 1776, by those of New York and Vermont in 1777, by the Massachusetts general court in 1778, the Massachusetts convention of 1779–80, the Tennessee convention of 1796 and the California convention of 1849. But the usual practice in

modern times is for the convention to appoint a number of committees among whom the several sections of the constitution are distributed for consideration and revision, after which such sections are reported to the convention in regular session or in committee of the whole. The more important committees common to three of the most recent constitutional conventions were arrangement and phraseology, banks, corporations, counties and towns, education, suffrage, judiciary, bill of rights, legislature, methods of amendment, municipal government, rules, taxation, submission and address, and miscellaneous. As a rule the members of these committees are appointed by the president of the convention. The Michigan convention of 1908 employed the following procedure: After the convention had been organized, 28 standing committees were authorized, the members of which were appointed by the president. The various propositions submitted by members were read and referred to the proper committee, on being reported by that committee were considered in committee of the whole and when reported by the latter were referred to a committee on arrangement and phraseology. When this last committee had reported upon the proposals, they were put upon their second reading and after this reading were voted upon; if adopted the proposals were again referred to the committee on arrangement and phraseology, which, after harmonizing all the proposals adopted by the convention, reported the complete revision as agreed upon. The committee of the whole then considered this revision section by section and reported to the convention, which then passed the revision to its third reading and voted upon it by articles and as a whole. Thus four different opportunities were presented for the discussion and amendment of proposals, and the committee on arrangement and phraseology had the opportunity to revise the language of each proposal after the committee of the whole had agreed upon it and before it was finally adopted; and as revised the proposals were again sent to this committee to be consolidated into complete and final form.

Submission of Constitutions to Popular Vote.— Since 1840, with a few exceptions, the States have followed the practice of submitting constitutions to popular vote, but the practice can hardly be said to have become fixed, since only about one-half of the State constitutions containing provisions for conventions require that the constitutions framed by these conventions be submitted to the people (California, Colorado, Idaho, Illinois, Maryland, Michigan, Missouri, Montana, Nebraska, New Hampshire, New York, Ohio, Oklahoma, Utah, Washington, West Virginia, Wyoming). Prior to 1784 the only constitutions formally submitted to the people were those of Massachusetts and New Hampshire, though in Pennsylvania in 1790 and in some of the other States a plan was pursued which accomplished about the same purpose; the Vermont constitution of 1786 (and also its later amendments to 1870) and the Georgia constitution of 1789 were ratified by special bodies chosen by the people for that express purpose. Constitutions were submitted for popular approval by New Hampshire in 1792, Connecticut in 1818, Maine in 1819, New York in 1821 (being the first State outside of New England to submit a constitution to the direct vote of the people), Rhode Island in 1824 (this constitution being rejected), Virginia in 1829 (her second constitution), Georgia in 1833 and 1839, Tennessee in 1834, Michigan and North Carolina in 1835, Pennsylvania in 1837–38 and Florida in 1839, but the conventions of Delaware in 1831, Mississippi in 1832 and Arkansas in 1836 did not submit their work to popular vote. Between 1840 and 1860 and from 1870 to 1890, almost without exception, the constitutions framed by conventions were submitted to the people for approval, but since 1890 the practice has been varied. Prior to 1890 there were 38 States, and since that time 10 others have been added to the Union (North Dakota, South Dakota, Montana and Washington in 1889; Idaho and Wyoming in 1890; Utah in 1896; Oklahoma in 1907; and New Mexico and Arizona in 1912). Of the 38 States 12 have held conventions to revise their fundamental laws (Mississippi, 1890; Kentucky, 1890; New York, 1894, 1915; South Carolina, 1895; Delaware, 1897; Louisiana, 1898, 1913; Alabama, 1901; Virginia, 1901–02; Michigan, 1907–08; Ohio, 1912; New Hampshire, 1889, 1902, 1912; Massachusetts, 1917–18), and in 1913 Vermont succeeded in modifying its constitution with the aid of a commission, while the amendments adopted in Oregon and California since 1902 are so numerous and fundamental as to amount virtually to revision. Four States unsuccessfully attempted to revise their constitutions (Rhode Island, 1898, 1899; Connecticut, 1902, 1907; Indiana, 1912; New York, 1915), and referenda submitted to ascertain the popular desire regarding the calling of conventions were negatived in Maryland (1907), Iowa (1900, 1910) and California, Indiana and South Dakota (1914), but Illinois, Indiana, Massachusetts, Nebraska and New Hampshire held conventions in 1917 and 1918.

Of the constitutions adopted since 1890 seven have been submitted without reservation — those of New York (1894), Utah (1895), Alabama (1901), Oklahoma (1907), Michigan (1908) and New Mexico and Arizona (1911), though the submission of the constitutions of Utah, Oklahoma, Arizona and New Mexico were required by the Congressional enabling acts. The constitutions of Mississippi (1890), South Carolina (1895), Delaware (1897), Louisiana (1898 and 1913) and Virginia (1902) were not submitted to the people in any manner (though in the case of Virginia the legislature, when calling the convention, required that its work should be submitted to the people); and the Kentucky constitution of 1891 was altered by the convention after the people had approved it. The Indiana legislature of 1911 drafted a new constitution, but its submission to the people was enjoined by the courts, and in November 1914 the voters defeated a proposal to summon a convention to revise the constitution. Nevertheless the legislature defied the popular mandate by passing the act of 1917 for a convention in 1918. In Ohio the constitution of 1851 was difficult of amendment or revision owing to the necessity of securing on referendum "a majority of all the electors voting at said election." Finally a convention was authorized and held in 1912 and at a special election in September of that year the convention submitted 42 separate prop-

ositions of which 34 were adopted. New Hampshire has no process of amending through the legislature, but every seven years submits a referendum in respect to the calling of a convention. The convention of 1889 submitted seven amendments of which five were adopted; the convention of 1902 submitted 10 amendments of which six were adopted; and the convention of 1912 submitted 12 amendments of which only four were adopted. In Rhode Island any revision recommended must be approved by two successive legislatures. In 1898 a proposed revision made by a commission of 15 persons passed the legislature but was defeated at the polls; with a few changes it was repassed and resubmitted in June 1899 but was rejected by a larger vote. In 1912 another commission of nine persons was appointed to recommend another revision and made its report in 1915, which after being approved by two assemblies was voted upon in 1917. The Connecticut constitution makes no provision for a convention, but in 1901, after a referendum, the legislature summoned a convention, the work of which was rejected at the polls in June 1902. In 1905 the legislature submitted a revised constitution but this too was rejected in November 1907. In Vermont amendments have suffered at popular elections, two out of 23 submitted in 1880 being accepted, none of the nine offered in 1890 and none of the four offered in 1900 being passed, wherefore in 1908 a commission of five was appointed to propose amendments; eight were proposed in January 1910 and after acceptance by two successive assemblies were passed by the voters in 1913. After Louisiana promulgated its constitution in 1898 every session of the legislature witnessed the introduction of numerous amendments until in 1913, owing to the necessity of making new arrangements to fund the bonded debt of the State, a convention was called which added an article respecting the debt, incorporated previously adopted amendments into the constitution and promulgated it without referendum. In 1912 North Carolina appointed a commission which in 1913 proposed 14 amendments to a special session of the legislature but though that body accepted 10 of these they were rejected at the polls in November 1914, though the constitution was later amended in 1916.

In connection with the submission of constitutions to popular approval, some attempts have been made either to enlarge or reduce the electorate for the purpose of voting on such constitutional changes. The legislature alone extended the electorate in New Jersey (1844) and Rhode Island (1841–42), but in 1821 this was done in New York with the aid of the electorate itself, while in Massachusetts in 1780 the convention did the extending with the assent of both legislature and electorate. The conventions of Virginia (1830) and Illinois (1869) had only the assent of the legislature, and the following conventions acted on their own initiative: Louisiana (1845, 1852), Michigan (1835), Texas (1845), Virginia (1851), West Virginia (1863), Tennessee (1834), Kansas (1859) and Arkansas (1868), the Tennessee and Arkansas conventions reducing the electorate in some particulars as well as extending it in others. Electorates have been reduced also by oaths of allegiance required by Reconstruction acts and by the conventions of Maryland (1864), Missouri (1865) and New York (1867).

Constitutional Restrictions upon Conventions.— Generally speaking, the only restrictions upon constitutional conventions are those expressly contained in the provisions of the State and Federal constitutions, or in the absence of such provisions, those implied in such constitutions and those implied from the limited functions of conventions. The existing constitutional organization is not affected by a constitutional convention since the latter acts under the restrictions either expressly or impliedly contained in the constitution in force at the time. Professor Dodd says that the convention "is a regular organ of the State (although as a rule called only at long intervals)— neither sovereign nor subordinate to the legislature, but independent within its proper sphere. Under this view the legislature cannot bind the convention as to what shall be placed in the constitution or as to the exercise of its proper duties . . . [which are] simply to propose a new constitution or to propose constitutional amendments to the people for approval; or in States where the submission of constitutions is not required, to frame and adopt a constitution if they think proper. . . . [Hence] constitutional conventions should not be subject to control by legislative acts." The new constitution does not become effective until promulgated by the convention, if such be the provisions of the existing constitution, or until ratified by the people, if this action be required. As an organ of the State and as a legislative body a convention must act in accordance with the provisions of the Federal Constitution regarding contracts, *ex post facto* laws and all other restrictions imposed upon the States by that instrument. If a State constitution provide for the revision or framing of the organic law of the State by the calling of a convention, then such convention is impliedly restricted to that one act and the exercise of such powers only as are necessary to accomplish its object. If the State constitution should make no provision for a convention, then such convention acts under the existing constitution and accordingly the governmental departments cannot be superseded or replaced until the new constitution framed by the convention become effective. Hence it is to be presumed theoretically that a constitutional convention is assembled for a limited and definite purpose and neither can nor does usurp the regular legislative, executive or judicial powers of the existing organs of government. (Consult, however, Hoar, R. S., 'Constitutional Conventions,' pp. 164–184). Yet this has not always been the case, particularly during the early Revolutionary and during the Civil War periods, notably in Missouri and the Southern States, though in the former period, as previously stated, the conventions primarily were provisional governments and the work of framing constitutions was only incidental. Analogous conditions obtained in Missouri in 1861–63 and in some of the other Southern States, so that the conventions were probably justified in acting beyond the limits of their regular duties. Some of the Reconstruction conventions in 1865–68, which were called to frame organic laws and establish governments, not only performed these duties but arrogated to themselves all the powers and functions of

the regular legislatures. Similarly the conventions of 1890 in Mississippi, of 1895 in South Carolina, of 1898 in Louisiana and of 1901 in Alabama acted as though they possessed powers in excess of those connected with the framing of constitutions. In the South Carolina convention a motion was even made that there be no session of the legislature and that the convention should do its work. The legislative act for the Michigan convention of 1907–08 required that the new constitution be submitted at the April election of 1908, but the convention decided upon the following November, and by mandamus proceedings compelled the Secretary of State to recognize the convention's supremacy. In 1867 and 1894 the New York convention sat beyond the time fixed by the legislature, as did also the Alabama convention of 1901, but while the New York delegates received no extra compensation, the Alabama convention resolved that the pay of its members should continue after the time allotted until the completion of the work. But it would seem that a convention has no power to appropriate money, since in most cases the constitutions provide that money shall be paid from the State treasury only upon a legislative appropriation. In a number of cases such actions have been questioned and have been held invalid by the courts, though other courts have upheld them.

IRVING E. RINES,
Author of 'History of the United States.'

CONVENTIONS, Revolutionary. Where the legal governments of countries have become the very grievances against which people rebel, the latter have no organ of expression save tumultuous or representative popular assemblies. The latter are usually called conventions. Thus, in England, the convention parliament of 1399 deposed Richard II and gave the crown to Henry IV; that of 1660, after the downfall of Richard Cromwell, proclaimed Charles II; that of 1689, after the flight of James II, proclaimed him abdicated and William III king. These were simply parliaments, except that there was no royal authority to call them. In Massachusetts, the convention of May 1689, at the same time as that in England, superseded the Andros government by one of the people. That of South Carolina in 1718, to form a provisional government in place of the proprietary government, is another instance. Of a similar character was the convention by which the first French Republic was declared in 1792, and under which the Revolution was carried on till the establishment of the Directory in 1795. In all these cases, the conventions were administrative bodies, governments pro tem. So during the Revolution, when the royal governors proclaimed the colonial assemblies dissolved, they were in the habit of reassembling as conventions, and they constituted the provincial government until regular constitutions were in force, which in fact they themselves often framed and adopted. The later constitutional conventions, creatures of State law, and limited to the preparation of a plan of government to be afterward voted on, have nothing whatever in common with the above, and are in fact only enlarged consulting boards, representative enough to imply fairly the entire public feeling. Of the first sort were the nullification convention in South Carolina in 1832 (see COMPROMISE OF 1833), and the secession conventions of 1860 and 1861. See CONVENTIONS, CONSTITUTIONAL; UNITED STATES — STATE CONSTITUTIONS; VIRGINIA CONVENTIONS OF THE REVOLUTION.

CONVERGENCE. Cases often occur where two animals of different groups, with a different ancestry and affinities, but with similar habits, so closely resemble each other that not only the ordinary observer, but the experienced naturalist, is deceived by their close resemblance. A familiar example is the whale, which so resembles a fish that by many it is even supposed to be one. Now, the whale is a mam-

mal, bringing forth its young alive, and suckling it. The cetaceans form an order by themselves. There are strong reasons for believing that they are the descendants of some group of land vertebrates which walked on all fours, but which, perhaps driven by competition, were forced to adopt marine life, and became wonderfully adapted to an aquatic life, during this process losing by disuse their hind limbs, while the fore legs became converted into fins. By adaptation to the same medium, a fish and a whale have a similar shape and a strong superficial resemblance. The same is the case with certain extinct whale-like lizards, such as the ichthyosaurs. These, with the plesiosaurs, are now supposed to have descended from some earlier four-footed terrestrial reptiles, which, becoming adapted to oceanic life, assumed a fish-like form.

Cases of convergence resulting from similar burrowing habits are seen in the *Amphibia* and reptiles. Certain amphibians (*Cæcilia*) and several extinct Carboniferous forms, have lost their limbs by disuse; they are worm-like, from adopting the habits of earthworms. Among the lizards the glass-snake (*Ophiosaurus*) and a few other forms have lost their legs in consequence of burrowing in the sand. There is a species (*Bipes*) in which a pair of legs are retained. Snakes have evidently descended from four-legged forms, the boas still retaining vestiges of the hind legs. It is not an easy matter to separate some of the legless lizards from small boas, owing to the convergence in their mode of life.

The thousands and tens of thousands of the boring larvæ of insects, belonging to quite different groups, have strikingly similar forms owing to their similar habits; thus the headless and apodous maggots of flies resemble those of ants, wasps and bees. Among jumping mammals, the kangaroo, the jerboa and jumping mice have similar large muscular hind legs, with a reduction in the number of toes, although they belong to different sub-classes or orders. The kangaroo is a marsupial and we have marsupial or kangaroo rats and mice which can be separated only by an expert from ordinary rodents. The koala mimics the bear, the pouched weasels look like genuine weasels, and so on.

A multitude of other examples can be cited to illustrate the effects of convergent habits, or the influence of similar conditions of life, or adaptation to such and such surroundings. It is most probable that many, if not the large majority, of the cases of mimicry among butterflies and other insects generally attributed to the action of natural selection, are examples of convergence, resulting from exposure to similar physical conditions of light, temperature, etc., which have produced similar styles of coloration, outlines in their wings, etc.

While convergence is not in itself a primary factor of organic evolution, use and disuse are such factors, and convergence in habits or modes of life, resulting in use or disuse of parts, have had much to do with the evolution of such extremely specialized groups as the whales, the snakes, the plesiosaurs and ichthyosaurs, as well as other minor groups of animals.

Convergence is of relatively rare occurrence in plants. However, the phenomenon of heterospory in Pteridophytes is usually supposed to have originated separately in the several groups.

CONVERGENT SERIES. See SERIES.

CONVERSANO, kŏn-vĕr-sä'nō, Italy, a town in the province of Bari, on a hill, 20 miles southeast of the town of Bari and five miles from the Adriatic coast. It is the seat of a bishop, and has a citadel, a handsome cathedral of the 13th century, several convents, among them San Benedetto, a diocesan seminary, a hospital and a castle which belonged to the family of Acquaviva. The district produces wine, oil, almonds, flax and cotton; and a good trade is carried on in these articles. The foundation of the town is attributed to the Etruscans. Pop. 15,112. Consult Simeon, S., 'Il duomo di Conversano' (Troni 1896).

CONVERSATION, the oral interchange of ideas among two or more persons. It may be formal or informal, in the latter sense differing little in meaning from "speech or talk." In its formal sense it is sometimes spoken of as "polite conversation," and it may cover a wide range of topics. As an art, conversation may be said to have flourished in the courts and palaces of Italy from the Middle Ages onward, and in the salons of France during the 16th, 17th and 18th centuries. In England, in the 17th and 18th centuries, conversation was perhaps at its best. Some of the "polite conversation" of this period has been preserved in the form of "table talk," but some of this literature might be better described as "monologue."

CONVERSE, Florence, American writer: b. New Orleans, 30 April 1871. She was graduated at Wellesley College in 1893, and was a member of the editorial staff of *The Churchman* (New York), 1900–08, when she joined the editorial staff of the *Atlantic Monthly*. Author of 'Diana Victrix,' a novel (1897); 'The Burden of Christopher' (1900); 'Long Will,' a romance (1903); 'The House of Prayer' (1908); 'A Masque of Sibyls' (1910); 'The Children of Light,' a novel (1912); 'The Story of Wellesley' (1915); 'Garments of Praise' (1921); 'Into the Void' (1926). She edited the 'Little Schoolmate Series,' and wrote short stories and poems which appeared in the *Atlantic Monthly, The Century* and other magazines.

CONVERSE, Frederick Shepherd, American composer: b. Newton, Mass., 5 Jan. 1871. He was educated at Harvard University and at the Royal Academy of Music, Munich. From 1899 to 1901 he was instructor in harmony in the New England Conservatory of Music. At Harvard he was instructor in music in 1901–04, and assistant professor 1904–07. His compositions include 'Sonata in A'; 'Suite for Piano'; 'Festival of Pan' (1904); 'Night and Day'; 'La belle dame sans merci'; 'Three Love Songs'; 'Quartet in A Minor'; 'Silent Noon'; 'Laudate Dominum'; 'The Pipe of Desire'; 'The Sacrifice'; 'Job,' an oratorio; and 'Ormazd,' a symphonic poem; 'The Immigrants,' an opera; a photo music drama, tone poems, etc.

CONVERSE, James Booth, American clergyman and author: b. Philadelphia, Pa., 8 April 1844; d. Morristown, Tenn., 31 Oct. 1914. He was graduated at Princeton 1865 and at Union Theological Seminary, Va., 1870. He was ordained in the Presbyterian ministry in

1871. He edited the *Christian Observer* 1872–79, and the *Christian Patriot* 1890–95. He published 'A Summer Vacation Abroad' (1879); 'The Bible and Land,' an argument in favor of single tax (1889); 'Uncle Sam's Bible, or Bible Teaching About Politics' (1899); 'There Shall Be No Poor' (1906), and also hundreds of articles in newspapers and magazines.

CONVERSION, (1) In theology, is originally the acceptation of Christianity by heathens. It is also used generally for a change from one religion to another, or in a narrower sense for a complete change of attitude toward God, involving a deeper conviction of the ultimate religious and moral truths. Considerable difference of opinion exists within the Christian Church as to the true nature and causes of conversion, especially in the sense last described. The difficulties hinge mainly on the extent of man's co-operation with Divine Grace, and the precise connection between conversion and repentance. In all cases of conversion the criterion of its validity is generally taken to be the resultant change of a man's character as manifested in his mode of life and thought, in the abstention from sin and in devotion to good works.

(2) *In logic.*— In the syllogistic method it is often necessary, in order to reduce the modes of the other figures to those of the first, to change the subject into attribute and the attribute into subject. This operation is called the conversion of propositions. In mathematical propositions the conversion is easily effected and the simplicity of the relations expressed renders evident the methods to be followed. The terms of an equation can be transposed without change, and the terms of an inequality by changing the sign; e. g., $A > B$ because $B < A$ and $A > B$ becomes $B < A$. In the qualitative propositions of logic the relations of the terms are more complex and the rules more precise. Here we have four kinds of propositions — the universal affirmative A, the universal negative E, the particular affirmative I and the particular negative O. How are these propositions converted? A may present two cases, it may express a definition in which the attribute has exactly the same extension as the subject and in this case the attribute can take the place of the subject without changing in any way the quantity of the proposition, e. g. *All men are rational animals* becomes *all rational animals are men.* This is an example of simple conversion. The universal affirmative A may also express the union of an attribute with a whole class of subjects without limiting this attribute to this class. In the conversion of such a proposition this indetermination of the attribute must be maintained e. g. *All men are mortal* is converted into *Some mortals are men.* A is here converted by limitation or *per accidens.* The universal negative E always expresses the exclusion of an attribute without limit from an entire class of subjects; after conversion, the proposition may consequently remain universal, thus, *No man is a quadruped* becomes by conversion *No quadruped is man.* Again we have here a case of simple conversion. The particular affirmative I expresses that an attribute belongs only to a part of the class named in the subject and in conversion this restriction must be maintained; thus, *Some mammals live in water* becomes *some animals that live in water are mammals.* The particular negative O cannot be converted by this simple transposition, for the sense would be altered altogether;— thus *Some man is not just* cannot be converted into *Some one just is not man* and *a fortiori* we may not convert a particular negative into a universal negative and say *No one just is man.* To convert a particular negative proposition therefore we must resort to a third mode of conversion and say, for example, *Some one not just is not some one not man.* This mode of conversion is known as contraposition. We have, therefore, three kinds of conversion, *simple,* in which the quantity of the proposition converted remains the same as that of the proposition to be converted, *limited* or *per accidens,* in which the universal proposition to be converted is changed into a particular proposition, and lastly conversion by *contraposition.* In all cases the quality of the proposition must remain the same. The Scholastics expressed the laws of conversion in the following mnemonic verses:

FEcI Simpliciter convertitur, EvA Per accid.
AltO per Contra. Sic fit conversio tota.

Consult Mill, J. S., 'Logic'; Keynes, J. N., 'Formal Logic' (3d ed., 1894).

Conversion.—(3) In common law, the wrongful assumption of dominion over the goods of another or others. The term conversion does not apply to the wrongful assumption of ownership of money or chattels real. Unauthorized destruction, sale or the use of the personal property of another constitutes conversion. There may be conversion when there is no wrong motive, as where an agent of A sells property believing it to belong to B when it really belonged to C. The wrongful taking may amount to larceny, to trespass or to a crime. Formerly the action for conversion was trover, but this has been abolished by statute both in Great Britain and the United States. The action is now called conversion. Usually the amount of damages recoverable is the value of the goods or the plaintiff's interest where he owns only a part. The plaintiff may either sue to recover the goods or he may claim damages. In the latter case title to the goods vests in the defendant if the judgment is satisfied. The courts are divided as to whether the defendant may mitigate his damages by a tender of the goods to the plaintiff. (4) In equity, an assumption that personal property has been converted into real property or vice-versa when the owner has shown in a proper manner that such was his intention. This is in accord with the well-known maxim that equity regards as done what ought to have been done. Likewise land may be converted into purchase money by a contract to sell made by the owner. Such intention, however, must be clearly expressed by the owner. The subject is of great importance on account of the radically different dispostion of realty and personality under inheritance and succession laws.

CONVERTER. See STEEL, BESSEMER PROCESS.

CONVERTIBLE GOVERNMENT NOTES. See CURRENCY.

CONVEYANCING, a term including both the science and the act of transferring titles to real estate from one person to another. In Hebrew times the modern form of transferring land was well known. In Rome property was

exchanged by ceremonial only until tht reign of Justinian when a simple legal process was instituted. Sometimes the term is applied in a restricted sense to the cumbrous forms which the feudal system has rendered necessary for the transference and tenure of landed property. When left to shape itself by individual practice, without legislative intervention, there were several causes rendering such conveyancing cumbrous and complex. The theory of the feudal tenures and hierachy remaining unchanged throughout the social revolution which had substantially abolished superiority and vassalage, and brought land out of feudality into commerce, the feudal ceremonies of the Middle Ages were necessarily retained, and they were adapted to fictions and explanations to modern exigencies. It seems strange that not many years have passed since in Scotland, when a parcel of land was bought and sold, a party of men assembled on it and went through the old form of feudal investiture by the delivery of so much earth and stone from the superior bailiff to the vassal's attorney, who took instruments and had the whole recorded at length by a notary of the empire. In England, from the want of the general system of registration known in Scotland, the complexities of conveyancing had become so inextricable, that one of the most approved forms of transference was a fictitious suit and judgment of possession called a fine and recovery. To these various sources of complexity must be added the timidity of conveyancers, who, afraid to commit themselves by attempting to abbreviate or reconstruct the forms which they find in existence, repeat them with additions from time to time as new circumstances must be provided for. Consequently to keep conveyancing within rational bounds the legislature, both in England and the United States, has interfered from time to time, by sweeping away excrescences, and providing brief and simple forms. All instruments under seal are spoken of as deeds, but the term deed is usually understood as applying to conveyances of land. Every person capable of holding lands (excepting idiots, persons of unsound minds, and infants), seized of or entitled to any estate or interest in lands, may alien such estate or interest at pleasure, subject to the restrictions and regulations prescribed by law. For a description of the method and procedure of modern conveyancing see DEED; TITLE-DEED; TITLE REGISTRATION; TITLE INSURANCE.

CONVEYOR, a machine which, when in a fixed position with regard to a supporting structure or surface, is capable of the transportation of bulk or packaged materials or solid objects in substantially a continuous and uniform flow. It may be designed to convey in any plane or combination of planes, from the horizontal to the vertical. When operating in a vertical plane a conveyor is generally designated as an elevator.

A conveyor usually consists of a housing, trough, or tube, with a means of propelling material through; or it may be a continuous moving line, carrying the material in buckets or pans or on a moving band. A limited group of conveyors move the material by a reciprocating or rotary motion of the trough or of mechanisms operating in the trough.

Conveyors are used in the science of handling materials, serving not only as movers of material but (equally as important) as the paramount factor of efficient manufacturing. Modern production methods, in order to co-ordinate operations, utilize conveyors of various types thus enabling departments to function as a unit. During the past forty years industry has introduced startling economies in handling raw materials and finished products. Conveyors have been credited both with assisting in this remarkable evolution and with relieving much human drudgery.

Conveyors suitable for handling bulk materials are belt conveyors, skip hoists, screw conveyors, apron conveyors, flight conveyors, drag conveyors, bucket conveyors, portable loaders, power drag scrapers, hydraulic and pneumatic conveyors, and continuous bulk flow conveyors.

Belt Conveyor.—Because of its small power consumption and large capacity (resulting from continuous delivery of material at a relatively high belt speed), the belt conveyor (Fig. 1) is especially well suited to the conveying of large quantities of bulk materials, such as coal, sand, ores, clay, coke, chemicals, pulpwood chips, etc., at a low cost per ton.

The conveyor's principal elements are the rubber-covered conveying belt, the troughed multiroll idlers over which the belt moves in the carrying run, the straight rolls over which the belt returns in the bottom run, the end pulleys, and the driving machinery.

When the material is not to be discharged over the end or when it is to be delivered into bins or bunkers at various points along the conveyor's travel, a traveling tripper is used. This tripper supports the belt and raises it sufficiently for the material to be discharged through the tripper's one-way or two-way chute to the storage space or to the floor below.

The conveying belt may be from 12 inches up to 60 inches wide, may operate at 300 feet to 600 feet per minute (or faster when handling grain), and may have its carrying-run-supporting idlers spaced from 3 feet to 5 feet apart, depending upon the capacity required, the size of lumps, and the weight of the material per cubic foot. The return idlers may be from 9 to 10 feet apart.

The use of the belt conveyor has advanced very rapidly during the past twenty years due to the perfection of antifriction idler rolls, which have prolonged the life of both the rolls and the belt and have further reduced the amount of power required per ton of material handled.

Skip Hoist.—In its simplest form, the skip hoist (Fig. 2) consists of a hoisting cable, a hoisting machine, and a rectangular bucket running on vertical or inclined tracks. It has few moving parts, is easy to operate, and is very dependable. It plays an important part in the handling of materials.

The skip hoist has been used extensively in mining operations for generations. It has always been the standard means for feeding blast furnaces. This is a service for which it is peculiarly adapted, not only because it delivers accurately measured charges at definite intervals of time, but also by reason of its reliability.

The skip hoist is well suited in general for high lifts and for such uses as storage of coal in high bins; elevation of ashes in boiler plants where large clinkers are produced; handling any large or coarsely broken material, as well as

finely crushed material; lifting abrasive or corrosive materials, since only the loader and bucket are in contact with the material handled.

Three types of skip hoist may be noted: (1) single bucket with no traveling counterweight to offset the dead weight of the bucket; (2) single bucket, counterweighted; and (3) two buckets, one balancing the other and ascending while the other is descending.

The electrical control is either entirely automatic, semiautomatic, or nonautomatic, depending on the requirements.

The loading of the bucket or skip may be accomplished by hand shoveling or by dumping material either into a hopper fitted with a hand-operated discharge-regulating gate or through an entirely automatic loader attached to the bottom of a storage hopper.

The machine's electrical control prevents overtravel of the bucket and is arranged to shut off the power when excessive slack has accumulated in the hoisting cable. The bucket may have a holding capacity of from 20 cubic feet up to 150 cubic feet or more. The normal cable speed may run from 40 to 450 feet per minute or more in the handling of such materials as coal, coke, ashes, limestone, and gravel.

Screw Conveyor.—This machine (Fig. 3) is used to excellent advantage in the conveying of such small-sized materials as grain, cement, cottonseed and its by-products, pulverized coal, sand, salt, starch, rice, sawdust, and sugar.

Screw conveyors are low in first cost, being exceedingly simple in construction and requiring very little headroom. The conveyor consists of a spiral mounted on a central shaft or pipe which serves to "screw" or push the material ahead in the all-steel or steel-lined wooden trough in which the spiral is rotated by suitable driving machinery. From the top of this trough the ends of the 8-, 10-, or 12-foot sections of a standard conveyor are supported at intermediate points by means of hanger bearings.

The diameter of the conveyor or spiral may be as small as 3 inches and as large as 24 inches. The material is discharged either over the end of the conveyor trough or through gates fitted in the trough's bottom where desired. Sometimes there are simply discharge holes, with no gates. When this type is used the material discharges through the first opening until the height of the pile reaches and closes up the hole. Then the discharge is through the next hole in the trough and so on until the storage is full.

Screw conveyors are used for moving materials horizontally or at slight inclines not exceeding about 15 degrees. As a rule their use is confined to the lighter classes of service. When they are employed for conveying ashes or other abrasive materials tending to cause rapid wear, the screw and the trough ought to be constructed of cast iron, manganese steel, or heat-treated steel.

The screw conveyor can often be placed in close quarters where other forms of conveyors could not work.

Apron Conveyor.—Apron conveyors (Fig. 4) for handling bulk materials, such as coal, sand, and crushed stone usually have two strands of roller chain traveling on suitable tracks in both the top and bottom runs, with overlapping steel pans tying the two chains together and serving as the apron on which the materials are conveyed. Stationary retaining sides or skirt boards are used to permit a greater depth of material to be carried.

Apron conveyors may be installed either horizontally or at inclines up to 26 degrees. Owing to their substantial steel construction, the pans will withstand the shock of dumping heavy masses of material on them. As the conveyor operates at a slow speed, usually from 20 to 100 feet per minute, the maintenance cost is low.

Flight Conveyor.—The flight or pusher type of conveyor (Fig. 5) was developed as a means for distributing coal and other nonabrasive materials horizontally or elevating it at angles ranging from horizontal to approximately 45 degrees. The material is received in a trough, pushed along by flights attached at intervals to a chain, and usually discharged through openings in the bottom of the trough which are provided with gates to be opened or closed as the conditions require. The bottom run does the conveying.

In the early days the flight conveyor was made with only a single strand of chain, the flights being fastened to it centrally. It usually was made of malleable iron with a thickened scraping edge, as well as with wearing pads for sliding the flights on steel tracks on the return run.

The need for greater capacity was met by providing two strands of chain attached to the ends of the flights. A further improvement is the use of rollers suspending the chain and flights, instead of permitting the latter to drag on the bottom of the trough; also the use of double strands of chain with rollers at the articulation points, carry the chain and flights.

The flight conveyor is not expensive in first cost, but it should be avoided for handling abrasive materials, such as ashes and sand, as the sliding or scraping action rapidly wears out the trough lining. The conveyor operates at speeds up to 150 feet per minute. It is suitable for either lumpy or small materials.

Drag Conveyor.—Drag-chain conveyors are nothing more than two or more strands of suitable type, sliding along in a trough and carrying the material with them (Fig. 6). Such conveyors are used a great deal for conveying sawdust.

The cast-steel drag chain often used in conveying hot or cold cement clinker, a very abrasive product, has broad wearing surfaces on its upper and lower sides. When the chain is worn on one side its useful life can be renewed by turning it over in the trough and using the other side. The head of each link acts as a pusher for conveying the material.

Drag-chain conveyors should be operated slowly to keep the wear to a minimum.

Bucket Conveyors

Under this heading will be considered the centrifugal-discharge, perfect-discharge, continuous bucket, gravity-discharge, and pivoted-bucket carrier types.

Centrifugal-Discharge Bucket Elevator.—This usually consists of malleable-iron buckets spaced at intervals on a strand of chain or on a rubber or canvas belt. It operates at a speed of 200 to 300 feet per minute. The material (coal, ashes) is delivered into a boot, from which it is scooped up by the buckets, elevated, and discharged or thrown by centrifugal force, while passing over the head sprocket, into a chute usually leading to a bin or a distributing conveyor. Although this is one of the earliest

types, it is still an ideal bucket elevator for nominal capacity, for handling material that does not have very large lumps, and for intermittent operation.

Perfect-Discharge Bucket Elevator.—This uses two strands of chain and has its buckets attached thereto at intervals. It has a pair of idler sprockets on the return side just below the head wheels to deflect the chains and completely invert the buckets, thereby effecting a perfect discharge. This elevator operates more slowly than the centrifugal type and because of its slower pick-up and discharge it causes less breakage of friable lumps in the material elevated. When it is used on an incline the deflector sprockets may be omitted.

Continuous Bucket Elevator.—This is made with steel buckets fastened continuously and very close together on one or two strands of chain or on a rubber or canvas belt (Fig. 7). The flanged front of each bucket forms a chute for the discharge from the succeeding bucket, thus effecting a clean discharge at slow speed. This slow speed, with the use of a feeding leg, permits the material to be fed directly into the buckets, and thus avoids the wear and strain of digging through an accumulation of crushed stone, ore, coal, or other material of a bulky or gritty character, in an elevator boot. It also reduces breakage of the material elevated and prolongs the elevator's life.

The bucket speed is usually about 100 feet per minute but it may be as high as 200 feet per minute. The continuous bucket elevator is more expensive than the centrifugal or the perfect discharge types, but it has greater capacity at slower speed than either of the others. It is more expensive because more buckets are required, and the chain and driving machinery must be heavier to carry the greater load and to handle the same quantity in a given time.

Gravity-Discharge Bucket Elevator.—As the conveying and elevating art progressed to the point where the foregoing types of bucket elevators had been developed for elevating materials and the flight conveyor for distributing them horizontally or at inclinations up to 45 degrees, engineers realized that a single unit for accomplishing both the elevating and the distributing operations would be desirable. To accomplish this purpose the gravity-discharge elevator was designed and built, and it has come into wide use.

It consists of steel buckets, approximately V-shaped in cross section, attached at intervals between two strands of chain. Coal or other material is received in a boot, from which it is scooped up by the buckets, as they pass around the foot wheels and is elevated to the desired height, where the buckets turn around wheels from a vertical to a horizontal position. The buckets then push the material along a steel trough and discharge it through gates or openings to an overhead bunker, to storage, or to another conveyor, as conditions require.

This type of elevator is not adapted for handling ashes or abrasive materials, which cause rapid wear of the steel trough linings, but it is admirably suited for the handling of hard coal, as the pickup in the boot is slow, and the material when discharged is allowed to slide gently down a chute, instead of being thrown or dropped. This lessens breakage of the material handled. The machine is flexible in its applications, with particular adaptability to varied paths of travel. It is very reliable in operation. It is used in retail coal pockets, locomotive coaling stations, and power houses.

Pivoted Bucket Carrier.—This derives its name from the fact that each bucket is pivotally suspended between two strands of chain and is maintained in the carrying position by gravity, thus permitting a single carrier to transport material horizontally, vertically, and again horizontally, or in any desired path within a vertical plane of travel (Fig. 8).

The advantages of the pivoted bucket carrier may be summarized as follows: (1) The material is carried and the bucket line is supported by rollers of large diameter. Destructive friction and the power required for operation are reduced to a minimum. (2) Using one machine both to elevate and to convey avoids transfers which are often troublesome and which take up valuable space and necessitate deep pits. In addition, only one driving unit is required. (3) The material handled is automatically discharged on the horizontal runs at any desired point by a mechanical dumper; and only at the dumper, during the entire cycle of operation, does the bucket change from its original upright position. (4) The buckets are overlapping in the horizontal runs, and they either right themselves or are righted by a separate device after having been turned by the mechanical dumper and discharged of their contents. The manner of righting the buckets depends upon the make of the carrier. (5) The slow speed, quiet operation, and almost complete absence of vibration result in long life for the conveyor.

Portable Loaders.—Conveyors may be further classified according to whether they are portable or stationary.

The portable loader (Fig. 9) is very popular for the loading of trucks with bulk materials, such as coal, sand, coke, and borings. It is made with either a belt, chain-and-flight, or chain-and-bucket elevating medium. Each type has its uses. The belt and the chain-and-flight types are also employed for unloading hopper-bottom cars of coal, and sand, and for piling the material alongside the track or delivering it to trucks.

The majority of these portable loaders are moved by hand on their four wheels, but for larger capacities the moving mechanism is a power-operated crawler of regular crane or tank type. This larger-capacity loader has on one side a platform on which the operator stands. From this position he controls the various functions of the machine by the convenient manipulation of hand levers.

With hand-propelled machines it is sometimes necessary (after they have been pushed close to the pile) to shovel the material onto the foot end. If the machine has been pushed hard enough into the material, however, it may not be necessary to do anything beyond merely assisting the flow of the material with a shovel. In this latter case no actual shoveling is required. The crawler loader has a self-feeder, and crawls under power as it digs and as it loads.

Power Drag Scraper.—The drag scraper is a simple conveyor which has proved its ability to save time and money in the handling and reclaiming of various bulk materials into and out of storage piles.

The scraper or scoop is operated to and fro by means of a double-drum-friction or geared

engine, a wire rope, and properly designed sheaves supported on posts or other form of anchorage. With this mechanism one man can store or reclaim most bulk materials at any normal capacity per hour. Used in conjunction with an elevator or loader to trucks or cars, large areas of storage can be reclaimed, and at a very small cost per ton. The system lends itself especially well to irregularly shaped property. A man in an operator's house maneuvers the full or empty scoop back and forth by means of an engine operated by a hand lever.

Hydraulic Conveyor.—A typical example is the application for the removal of ashes from a large power plant installation. Ashes from the boilers are fed into a trench or pipe system by means of a water jet of high velocity, and are kept moving to the final disposition point by means of additional jets.

Pneumatic Conveyor.—A conveyor employing air, suction or pressure, (designated as a pneumatic conveyor) frequently is preferable to mechanical conveying. The major parts of a pneumatic conveyor, consisting of a pump and a pipeline system through which air and material move to a device for separating air from material, offer a conveyor with flexibility often beyond the range of a mechanical conveyor. Ideal installations are for the unloading of coal, grain, and similar bulk materials from boats, railroad box cars, and bins. Such conveyors are used extensively for collecting and conveying dust and waste particles within the scope of large industrial plants.

Continuous Bulk-Flow Conveyor.—This is one of several types developed to meet the demand for a totally enclosed, dust-tight, compact, self-feeding unit for handling flowable bulk materials in a continuous mass (Fig. 10). The moving element is an endless chain having either solid flights closely and rigidly (or pivotally) attached or open flights of the skeleton type, cast integrally with each chain link.

The application shown is a boilerhouse installation whereby stoker coal may be conveyed both horizontally and vertically in one simple compact unit, instead of having to be delivered by a horizontal conveyor with feeder to a separate vertical elevator. The unit is self-feeding, as the coal flows from bin to upper run, is conveyed to right, dropped to lower run, and conveyed in a continuous mass to the discharge. The horizontal screw conveyor is an auxiliary unit to distribute the coal over the stoker hoppers. Steeply inclined and vertical units, serving as elevators, are made with a loop-type foot end so that the product handled can be fed directly to the carrying run.

Continuous bulk-flow conveyors and elevators are employed extensively in numerous industries handling materials under conditions requiring single units for gentle moving of material within dust-tight enclosures operating in horizontal, vertical, inclined, and curvilinear paths, with minimum requirements for support and space. Materials that are sticky, wet, corrosive, abrasive, or made up of hard lumps should not be handled by this method of conveying.

Conveyors for every industry have been developed to meet the special requirements of all types of production functions. The models described below are typical.

Overhead Trolley Conveyor.—This consists of an endless chain attached to trolleys equipped with antifriction bearings operating on a continuous overhead track (Fig. 11). A variety of parts and commodities, ranging in weight from a few pounds to several thousand pounds, may be handled on this type of conveyor. To contain these parts, several types of racks, pans, hooks, and baskets may be attached to the trolley frames. The path of this conveyor can be deflected either horizontally or vertically. A single unit may employ 3,000 feet of chain and operate throughout several stories of a large building, or it may connect several buildings. This conveyor, whose initial cost and upkeep are low, is flexible in use and is employed extensively in continuous-production plants of all types.

Apron Conveyor.—A popular type for handling bulk materials, this conveyor is also widely used in foundries and steel mills for continuous moving of hot or cold metals (Fig. 12).

Triple-Strand Chain Conveyor.—This conveyor for handling packaged materials is low in first cost as well as economical in upkeep, and it serves as an important machine for industrial requirements (Fig. 13). Equipped with reversible drive, this unit will elevate or lower packages as desired.

Double-Strand Chain Conveyor.—This is suited for the fast and continuous handling of packed or crated food products to refrigerator cars (Fig. 14). Automatic transfer is employed, delivering to a portable section of a gravity-roll conveyor placed opposite car doors. Conveyors of this type may be equipped with swivel-type chains traveling over practically any desired path.

Tray Elevators.—For the conveying in a vertical path of such items as cases, cartons, barrels, rolls of materials, and similar merchandise, tray elevators of the type shown here (Fig. 15), or similar models, are well established in warehouses, storage buildings, and marine piers. Constructed of two endless chains operating over head and foot sprockets, and with fingered bottom trays pivotally supported at intervals between two chains, this unit in operation will automatically pick up packages from skids on ascending travel and automatically discharge them on skids on descending travel. Similar tray elevators have been installed to operate through six or more floors of storage, handling rolls of paper up to 30 inches in diameter, 72 inches in length, and 1,500 pounds in weight.

Roller Conveyor.—Operating without mechanical power, this machine (often referred to as a gravity-roll conveyor) will convey downgrade on ball-bearing rollers practically all types of merchandise, commodities, and materials having at least one smooth side or surface (Fig. 14, lower portion). Rollers are fitted to steel frames and may be assembled into a variety of sections, including complete spirals for lowering merchandise between warehouse floors.

EDWARD F. MULLIN,
Consulting Engineer.

CONVICT, a term technically applicable to any person who, having been convicted of violating penal laws by a competent tribunal, is consequently deprived of liberty for a specified time, during which he is subject to confinement and labor. In both England and the United States the convict is a person who has thus been found guilty by jury; and in the United States, the term is usually applied to the inmate of a state

prison. The status of the convict may be terminated by a reversal of judgment, by unqualified pardon, or by termination of the sentence.

While not placed outside the law during the period of his sentence, the convict meanwhile loses his civil rights. He may sue and be sued in most states, may possess, receive, or grant personal property, and appear as witness in court action; but he may not hold public office, nor serve as juror, nor vote. He suffers, in addition, an indefinite onus of social stigma.

Popularly, the term convict denotes any person serving a prison sentence for a long time.

CONVICT LABOR. The introduction of industry into prison life, apart from its use to keep penitentiaries in good order and good repair, is a product of 19th century reforms. Isolated cases it is true occurred before. Mabillon, a Benedictine monk of the 17th century, urged a cellular system of imprisonment, labor in the cells and gardens where prisoners might rest after the day's work. In 1704 Pope Clement XI opened a prison at Rome, where the industrial feature proved successful in the case of boys. A famous prison built in Ghent in 1775 by Viscount Vilain XIV had a well-organized labor system, intended to benefit the prisoner and make him useful to the state. Two years afterward John Howard published his work on *Prison Reform.* But in practice before the beginning of the 19th century, and well into it, labor was considered in a penological bearing only as offering the possibility of severer punishment, an idea excellently typified by the Roman system of punishing the city slave by sending him to the country treadmill, or by the terrible toil of the galley slave in Italy and France. This penal point of view was followed by the fiscal interest of the state and to a certain degree intermixed with it; the state will save, and if possible, make money by means of its use of the time and strength of the convict. Then the disciplinary interest became predominant; the convict will furnish us less trouble if we keep him at work. A further step is taken when the object of convict labor becomes moral and the prisoner is put to work to keep him from idleness, spring of so much vice, and to promote his ability to earn an honest livelihood upon his release. In the latest among these stages a distinct effort is made to furnish the convict with decent and pleasant work, and the old scheme of choosing the most revolting and dangerous, the most degrading and monotonous task has been done away with.

Unfortunately the evolution hinted at has not been completed, and traces of each of the ideals mentioned may still be found in the various systems of Europe and the United States. "At hard labor," for example, is still felt to be a degrading and aggravating addition to the sentence of detention. As far as actual business management is concerned there are two methods of convict labor. In the first, where the "product or profits of labor is shared by the state with private individuals or firms," we may mention three divisions, sufficiently characterized by their common names: the contract system, the piece-price system and the lease system. The second general class, "systems under which convicts are worked wholly for the benefit of the state" or its parts, again falls into three divisions, the public-account system, the state-use system and the ways and works system. Theoretically the piece-price system is best in the former class, as it keeps discipline in the hands of prison authorities and leaves business to the enterpeneur; morever it lacks the faults of the contract system, which to a degree interferes with regenerating influences by the very monotony of highly specialized and largely divided industries. In the second class, the public account system, by which goods were made in prison, under the control of regular prison officers, and were sold in a rather haphazard way, has bulked so largely in the public eye, by reason of the attacks made on it by the representatives of free labor (who overlook the fact that cheaper production is offset by slower production), that the other subclasses have been overlooked. Of these systems the most popular is that which provides that all results of convict labor should be used by the state, and yet this as a system could equally well be attacked by labor unions, which naturally desire to supply state institutions as well as other sources of demand. Although it has but a limited field, the state-use system is growing; it is used in most of the Northern states and is authorized by the federal government for the Fort Leavenworth penitentiary. Another system is the state farm system, under which, as in several Southern and some Northern states, large plantations are purchased to be operated by the state with convict labor, part of the products being used to maintain the prisoners and the unused portions being sold in the public markets. In the North many of these farms are adjacent to the prisons so that they may be worked by the inmates. The state farm system has been in vogue in Massachusetts many years, and in some of the Southern states they are highly profitable to the state. In favor of the system it may be said that the prisoners can be kept in permanent places; they are not exposed to public view; they may be instructed in the ways of becoming self-supporting; they have healthful outdoor life; and the system does not arouse a great amount of public opposition.

The lease system calls for special notice. Its particular habitat is the South. After the Civil war a remodeling of the penitentiary system was demanded because of the addition of the Negro factor to the problem, more than 90 per cent of convicts in most states being Negroes. Both expense and the need of outdoor work on the part of the Negro made impracticable the continued use of walled penitentiaries, which moreover would have been quite inadequate under new conditions. The lease system came into general use in the late 1840's, and felons were worked in coal and iron-mills, sawmills and farms. A chief inspector had general charge, but the responsibility, which was scarcely more than nominal, was upon the lessee and his inspectors and physicians. In many states this system gave rise to horrible abuses. In Georgia it was abolished in 1897 and the state camp system put in its place. The death rate dropped from over 7 to 1.4 per cent in four years. Pay was allowed the prisoner who volunteered to do extra work, and the more brutal forms of corporal punishment abolished. But even in Georgia the county chain gang, made up of minor offenders, under supervision of county

road commissioners, is still cruel and vicious. Worse than the county chain gang of Georgia, where only 45 per cent are hired to private individuals, is the system in other States. Alabama, notably by its contract law of 1901, which was declared unconstitutional in 1903 by a United States Circuit Court judge, made possible the following scheme of peonage: A minor offender and often a perfectly innocent person is sentenced to a light fine which the constable offers to pay for a certain number of months' work. At the expiration of this period a new charge is trumped up, or the negro induced to attempt escape, he is again tried and sent to the convict camp or fined for the benefit of the constable and his backers. The universal disapproval of this system in the South and the prompt action of the Federal authorities has led to the abolition of its worst features.

CONVOCATION, an assembly of the clergy of the Church of England, belonging either to the province of Canterbury or to that of York, to consult on ecclesiastical matters. In both provinces the Convocation consists of two houses, an upper and a lower. In the former sit the bishops and in the latter the deans and archdeacons, along with the proctors, who represent the inferior clergy and the chapters of cathedral churches. In the Convocation of the province of York the usual practice has always been for all the members to sit in one house. Originally convocations were merely ecclesiastical councils that had no special privileges or recognized political status, but gradually they came to assume their present form, being endowed with the right of passing canons, of determining their own taxation, etc. When thus formed into an assembly, having certain political as well as ecclesiastical functions, there was only one Convocation for all England, and this lasted down to the beginning of the 14th century, when the clergy of the two provinces began to meet in separate Convocations. The archbishop of each province has the right of summoning Convocation, but he cannot do so without the royal consent, nor can Convocation pass any canons without the same authority; and from its judicial proceedings there lies an appeal to the sovereign in council. In 1664 the practice of granting subsidies to the Crown, in the exercise of the right of self-taxation enjoyed by the clergy, was discontinued, and since that time their functions have been mostly formal. In the reigns of William III and Queen Anne the Convocation of the province of Canterbury recovered some degree of importance, but in 1717 that temporary influence was again lost, and from that year down to a recent period the practice was to prorogue the Convocation as soon as it had assembled. Since 1852, however, the Canterbury Convocation has met regularly two or three times a year for the transaction of business relating to the Church, and in 1861 it exercised its legislative power, the first time for a long series of years. On the opening of a new Parliament a new Convocation is summoned. If the Crown desires to refer any question to Convocation, «letters of business» are issued, directing that question to be taken into consideration. Other bodies in touch with the work of Convocation are the House of Laymen and the Representative Church Council, which, however, are without constitutional status in the Church of England.

The term Convocation is also applied to the legislative body of the University of Oxford, composed of all masters of arts, and has the power of acceptance or rejection of statutes passed by the Hebdomadal Council and the Congregation. Consult Trevor, 'The Convocation of the Two Provinces: Their Origin, Constitution, and Forms of Proceeding' (London 1854); Lansbury, 'History of the Convocation of the Church of England' (London 1842).

CONVOLVULACEÆ, kŏn-vŏl-vū-lā'sē-ē, or **BIND'WEEDS,** an order of herbaceous or shrubby plants, usually twining, with plaited tubular corolla, imbricated calyx, alternate undivided or lobed and pinnatifid leaves; bell-shaped flowers, axillary or terminal; five free stamens; and fruit with two or three cells. Many of the order contain a milky and resinous juice possessing purgative properties more or less drastic. Jalap is derived from the *Ipomœa purga,* and inhabitant of Mexico and the southern parts of the United States; and scammony (*C. scammonia*) is a resinous substance possessed of nearly the same properties as jalap. Some species of the order have tuberous and fleshy roots containing a farinaceous and saccharine principle which fits them for food for man and beast. Among these is *Ipomœa batatas,* the sweet potato, originally from India or South America, but now cultivated in all countries where it can stand the climate. *C. scoparius* and *floridus* yield by distillation an essential oil called oil of rhodium, which has a bitter balsamic flavor. Their wood, when powdered, forms an agreeable snuff, and when burned is very fragrant. There are about 40 genera and 900 species widely distributed. The various species of *Cuscuta,* the dodders (q.v.) or bindweeds, which are parasitic on

other plants and lack leaves and green color entirely are often considered as belonging to the family.

CONVOLVULIN, kŏn-vŏl'vū-lĭn, the purgative constituent of jalap ($C_{31}H_{50}O_{16}$), obtained from the root by treatment with water and strong alcohol. The alcoholic extract is mixed with water, boiled with animal charcoal, filtered, evaporated and treated with ether as long as anything dissolves. Pure convolvulin is transparent and colorless, brittle at 212° F., fuses at a higher temperature to a clear liquid and is decomposed by strong heating. It is almost insoluble in water and quite so in ether, but soluble in alcohol. It has no taste or smell. In doses of two or three grains it is a powerful purgative, and in larger quantities is fatal to animals. By treatment with alkalis it is converted into convolvulic acid, and by acids into convolvulinol ($C_{18}H_{24}O_3$) and glucose.

CONVOLVULUS, the typical genus of the natural order *Convolvulaceæ* (q.v.), or morning-glory family, formerly known as bindweeds. There are about 150 species widely distributed in temperate and tropical climates, some 15 of which are found throughout the southern and western United States.

CONVOY (Fr. *convoyer,* "to accompany"), in nautical language, a fleet of merchantmen bound on a voyage to some particular port or general rendezvous under the protection of a ship or ships of war. The name is also given to the ship or ships appointed to conduct and defend them on their passage thither. It is used in a military sense for a wagon train under an escort of troops, and loosely for the escort itself.

CONVULSIONISTS, or CONVULSIONARIES, a sect of religious fanatics originating among the Jansenists of France about 1730. Three years previously a charitable and ascetic deacon of Paris, one Francis, died, and was buried in the cemetery of Saint Médard, in one of the suburbs of the capital. Reports of miracles wrought at his tomb spread among the people, and soon the cemetery was the scene of extraordinary manifestations. As the devotees approached the tomb many were seized with convulsions, or took to dancing and contortions, accompanied by shouts and other eccentric demonstrations. Some of their utterances were accounted as prophecies miraculously inspired by the venerated dead. Most of them were directed to the support of the Jansenist doctrines; but some of the fanatics, by denouncing the throne, and predicting its downfall as well as that of the Church, drew the attention of the government and the ecclesiastical authorities. The cemetery was ordered to be closed; but the same virtue that seemed to be possessed by the tomb was also inherent in earth surreptitiously obtained from it, and the manifestations continued. Imprisonment failed to stop them, but the fanaticism gradually died out in about 20 years. An account of this sect was published by P. F. Mathieu, in Paris in 1864, entitled 'Histoire des miracles et des Convulsions-Saint Médard.' Consult also Carré de Montgerom, 'La vérité des miracles opérés à l'intercession de M. de Paris et autres appellans' (3 vols., Paris 1737).

CONVULSIONS. A convulsion is a violent involuntary contraction or series of contractions of the voluntary muscles. It occurs in many conditions, both functional and organic, namely, tetany, hysteria, epilepsy, tetanus (lock jaw), uræmia, eclampsia and chorea (Saint Vitus dance), occurring most frequently in infants. The convulsion may be local or general, tonic or clonic in character, and is due to a hypersensitive nervous system or relatively greater excitability of the brain and the undeveloped power of inhibitory control. In children it may be reflexly due to teething, phimosis, rachitis, eating of indigestible articles of food, intestinal worms, injuries to the head, constipation, foreign bodies in the ear and nose, and fever from any cause or toxæmia of any kind. Convulsions at the time of birth may be due to cerebral hæmorrhage following a forceps delivery, or brain tumor, brain abscess and hydrocephalus.

Uræmia is the result of kidney disease, as is also eclampsia which occurs during the pregnant state. The convulsions are tonic and clonic in character, frequently occur without warning and in people apparently in perfect health the attack may come on at any time — the eyes become fixed at first and then roll from side to side, the convulsive movements first appear about the mouth, which begins to twitch and is drawn to one side, the entire face becoming distorted. They extend rapidly to the arms, the body, and then finally to the legs. The breathing is stertorous, the face congested and flushed, the patient foams at the mouth and often bites his tongue. During the convulsion, which may last from a few seconds to a half hour, the patient is profoundly unconscious, and after the movements cease passes into a condition of coma which lasts for a longer or shorter period. The convulsions are frequently repeated.

Chorea occurs most frequently in children, and the convulsions or twitchings are of a clonic character and affect groups of muscles. The twitchings may be slight or very severe so as to interfere with speech, eating, locomotion and coherent voluntary bodily movements. It may affect one side of the body, as one arm and leg, when it is known as hemichorea, or it may affect both sides. The twitching movements are greatly exaggerated when the patient endeavors to perform a voluntary act. Consciousness is always present.

In epilepsy (q.v.) the convulsions resemble those described under uræmia. There seems to be a regular order of movements followed out, preceded by aura, the patient becomes unconscious, froths at the mouth, bites his tongue, the pupils dilate and there is an involuntary passage of urine and fæces. The convulsions last a few minutes, and on recovery, the patient is left in a semi-comatose condition, complains of headache, and then falls off into a restless sleep. The attacks also frequently occur at night while asleep.

Hysteria shows a great variety of manifestations. The convulsions may involve only the lower extremity or the head and neck. There is a condition known as hystero-epilepsy. There is no aura, the attacks are much prolonged and purposeful and tonic in character. The bladder and rectal functions are not disturbed. There is no complete loss of consciousness.

The patients seldom injure themselves, in fact they seem to protect themselves from injury.

In children the convulsions usually begin suddenly, although they may be preceded by a rolling of the eyes upward and sideways and by slight twitching of the muscles of the face. Unconsciousness soon supervenes, the eyes remain fixed and staring, the head is thrown backward, and the entire body stiffens out only to be followed by clonic contractions. There is a series of contractions and relaxations. The face assumes different expressions or grimaces, the teeth become set, there is a frothing at the mouth and the color of the face becomes dusky and cyanotic. The breathing is labored and heavy, urine and fæces may be voided involuntarily. After going through several convulsions the child soon passes into a deep sleep and then awakens with an apparent interest in his surroundings. These convulsions usually indicate the approach of some disease or reflex irritation somewhere, and should be considered as a serious condition until the cause is discovered. The convulsion in the child is analogous to the chill in the adult, it precedes such diseases as pneumonia, cerebrospinal meningitis, grippe, intestinal disturbances, etc. A convulsion is a symptom and not a disease, and therefore it is never directly the cause of death.

As to treatment, it is of great importance to control the convulsion before trying to find out its cause. In children this is done by placing the child in a bath of hot water with mustard and keeping it there until the skin is reddened. If the convulsions persist, the child should be put under the influence of chloroform until the convulsive tendency has disappeared. When the convulsion is controlled, search is then made for the cause. If the digestive tract is found to be at fault, the child is given a dose of castor oil, and a high rectal enema of soapsuds is given as a matter of routine to empty the lower bowel. After the bowel is cleared and the child still shows a tendency toward convulsions, a rectal injection of 10 grains of sodium bromide and 3 grains of chloral hydrate may be given for a child five years old. In very severe cases it is justifiable to give a hypodermic of morphia in proper dose. The room should be kept noiseless and an icebag placed to the head. It is always a good plan to examine the enema stool in search for intestinal parasites, foreign bodies or undigested particles or lumps of food. A child who is very nervous and is easily excited by physical impressions should be kept very quiet. Genital abnormalities should be properly treated, a child with a tight or adherent prepuce when circumcised becomes free from convulsions. Foreign bodies should be removed from the ears and nose. A child with rachitis should be built up, kept out of doors in the sun, and given the proper kind of food and tonics. Hydrocephalus may be treated by tapping the ventricles of the brain through the anterior fontanelle and so drain off some of the fluid or tap the spinal cord to drain it off that way and so relieve the intra-cranial pressure. Anæmia and malnutrition should be treated if found to be the cause.

Convulsions due to tumors of the brain or brain abscess cannot be treated unless they be in a position accessible to the surgeon. Convulsions due to uræmia are very serious and need very urgent treatment; a mouth gag should be inserted into the mouth to prevent the patient from biting his tongue, blood letting is done from one of the veins at the bend of the elbow to lower the blood pressure and rid the system of a certain amount of toxins; usually 500 c.c. is withdrawn at one time, hot packs are given or the electric baker is placed over the patient to induce profuse perspiration, pilocarpine one-tenth grain by hypo is sometimes used but is not safe. In eclampsia the uterus is emptied as soon and as rapidly as possible, using ether and oxygen as anæsthetic; chloroform should never be used. Ether and oxygen are used to control the convulsions until the time for operation. A mouth gag is the first thing to be placed in the mouth. In epilepsy the convulsions usually do not last long. Prevent the patient from injuring and biting his tongue. Loosen all his clothing and see that he lies in a well-padded place and away from solid objects. Chloroform is used if the convulsion is very severe. Epilepsy found to be due to depressed fracture of the skull is often cured of any future attacks when operated upon and a button of bone removed, the intracranial pressure being thus relieved. In chorea, the child should be kept as quiet as possible, free from all mental and physical strain. If tonsils and adenoids are present these should be removed as they frequently act as a focus of infection in causing this disease. Teeth and sinuses should also be examined for the same reason. Its food should be easily digested and nourishing; arsenic in the form of Fowler's solution is the best remedy. If traces of rheumatism are present it is combined with the salicylates. Bromides and chloral are given to quiet and control the spasmodic movements. Iron is also given as a tonic. In hysteria the best way to check the convulsion is by dashing a glass of cold water into the patient's face. A hypo of apomorphine, one-tenth grain, causes sickness of the stomach and immediately arrests the attack. A teaspoonful of aromatic spirits of ammonia may be given. Convulsions due to meningitis, tetanus, brain abscess and tumors of the brain are treated along general principles.

HENRY H. BEINFIELD, M.D.

CONWAY, Hugh. See FARGUS, FREDERICK JOHN.

CONWAY, Moncure Daniel, American clergyman and author: b. Stafford County, Va., 17 March 1832; d. New York 1907. He was graduated at Dickinson College in 1849, entered the Methodist ministry in 1850, and later studied at the Harvard Divinity School. He had become imbued with rationalistic ideas and attempted to preach them on his return to Virginia, but was obliged to leave the State. He became pastor of a Unitarian church in Washington, D. C., but was obliged to leave this charge, owing to his opposition to slavery. He secured another pastorate in Cincinnati, and while there wrote several volumes and edited the *Dial.* In this periodical and later in *The Commonwealth* of Boston he earnestly advocated emancipation, and in 1863 went to England to explain the cause of the Civil War. From 1863 to 1884 he was minister at South Place Chapel in London, England, and again, 1892–97. He returned to America near the

close of the century and made his home in New York. His published books include 'Tracts for To-day' (1857); 'The Rejected Stone' (1861); 'The Golden Hour' (1862); 'Testimonies Concerning Slavery' (1864); 'The Earthward Pilgrimage' (1870); 'Sacred Anthology' (edited) (1872); 'Idols and Ideals' (1874); 'Travels in South Kensington' (1875); 'Demonology and Devil Lore' (1879); 'The Wandering Jew' (1880); 'Thomas Carlyle' (1881); 'Emerson at Home and Abroad' (1882); 'George Washington and Mount Vernon'; 'Omitted Chapters of History Disclosed in the Life of Edmund Randolph' (1887); 'Pine and Palm,' a novel (1887); 'Life of Nathaniel Hawthorne' (1890); 'Prisms of Air,' a novel (1891); 'Life of Thomas Paine' (1892); 'Barons of the Potomac and the Rappahannock' (1892); 'Centenary History of South Place Chapel' (1893); 'Solomon and Solomonic Literature' (1899); 'Autobiography' (1904); 'My Pilgrimage to the Wise Men of the East' (1906); 'Addresses and Reprints, 1850–1907' (Boston 1909). He edited the 'Works of Thomas Paine' (1893–96).

CONWAY, Robert Seymour, English classical philologist: b. Stoke Newington 1864. He was educated at Caius College, Cambridge. He was Fellow of Gonville and Caius College in 1888–94, classical lecturer in Newnham College in 1887–93, and professor of Latin, University College, Cardiff, Wales, in 1893–1903, and Hulme professor of Latin, in Victoria University, Manchester (1903–29). He wrote 'Verner's Law in Italy' (1887); and 'Virgil, an Inaugural Lecture' (1903), collaborated in the translation of 'Brugmann's Comparative Grammar' (1888–95); 'The Restored Pronunciation of Greek and Latin' (1896); 'The Italic Dialects' (1897); 'Dialectorum Italicarum Exempla' (1898); 'The Pre-Hellenic Inscriptions of Praesos' (1903); 'Harvard Lectures on the Vergilean Age' (1928). D. 28 Sept. 1933.

CONWAY, Thomas, Irish soldier of fortune: b. Ireland, 27 Feb. 1733; d. about 1800. He was educated in France, and entering the army there became a colonel. He came to America in 1777 and offering his services to the Continental Congress was appointed brigadier-general and subsequently inspector-general, with the rank of major-general. He intrigued to have Washington superseded by General Gates, and he and his associates were known as "Conway's Cabal." He resigned in 1778, went to France and was made governor of Pondicherry and the French settlements in Hindustan. In 1792 he was appointed commander of the Royalist forces in the south of France, but on the success of the Revolutionists fled from the country.

CONWAY OF ALLINGTON, 1st Baron (William Martin) English explorer: b. Rochester, England, 1856; d. London, 19 April 1937. He was educated at Trinity College, Cambridge; professor of art at University College, Liverpool, 1885–88, and Slade professor of fine arts at Cambridge 1901–04. In 1892 he traveled extensively in the Himalayas and in the Alps in 1894; he explored the interior of Spitzbergen in 1896–97, and the Bolivian Andes in 1898, as well as the glaciers of Tierra del Fuego. Among the high peaks he ascended are one in the Himalayas of 23,000 feet, and Aconcagua, Illimani and Sorata in the Andes. He was created baron in 1931, received a gold medal for mountain surveys at the Paris Exhibition in 1900, and the founder's medal of the Royal Geographical Society, 1905. He published 'Woodcutters of the Netherlands in the 15th Century' (1884); 'The Artistic Development of Reynolds and Gainsborough' (1886); 'Early Flemish Artists' (1887); 'Literary Remains of Albrecht Dürer' (1889); 'Dawn of Art in the Ancient World' (1891); 'Climbers' Guides to the Alps' (1890); 'Climbing and Exploration in the Karakoram-Himalayas' (1894); 'The Alps from End to End' (1895); 'The First Crossing of Spitzbergen' (1897); 'With Ski and Sledge over Arctic Glaciers' (1898); 'The Bolivian Andes' (1901); 'Aconcagua and Tierra del Fuego' (1902); 'Great Masters' (1904); 'Early Voyages to Spitzbergen' (1904); 'No Man's Land' (1906); 'The Sport of Collecting' (1904); 'Art Treasures of Soviet Russia' (1925).

CONWAY, Ark., city and Faulkner County seat; alt. 315 feet; on the Missouri Pacific Railroad; 30m. N. of Little Rock. Lumber, cotton, poultry, dairy and garden truck products are grown in the surrounding country. In the city cotton is ginned and pressed, and all-steel bus bodies are manufactured. Conway is an educational center with three colleges: Hendrix College (coeducational; Southern Methodist, 1884; moved here from Altus in 1890); Arkansas State Teachers College; and Central College (Baptist) for women. Settled about 1871, and named for Arkansas's first governor, Conway became a city in 1900. Government is administered by a mayor and council. Pop. (1930) 5,534; (1940) 5,782.

CONWAY, N. H., town in Carroll County; alt. 465 feet; in a bend of the Saco River where it meets the Swift River, at the SE. tip of the White Mountain National Forest; 66m. NW. of Dover; on the Boston and Maine Railroad. Its main villages are: Conway, in an intervale with rich soil; and North Conway, famous for White Horse Cliff on Moat Mountain. There are lumber mills and woodworking plants (birchbark novelties). Pop. (1940) 3,651.

CONWAY, S. C., town and Horry County seat; alt. 25 feet; on the Waccamaw River and the Atlantic Coast Line; 97m. NE. of Charleston. Industries includes manufactures of cotton, tobacco, lumber. Pop. (1940) 5,066.

CONWAY, CONWY, or ABERCONWAY, Wales, town and parliamentary borough in the county of Carnarvon, about 14 miles east-northeast of Bangor. It is picturesquely situated on the left bank of the Conway River, and is surrounded by an old wall still in good preservation, 12 feet thick, and fortified with towers and battlements. The old castle of Conway, erected toward the end of the 13th century by Edward I, is one of the most magnificent structures of the kind in England. It is one mile in circumference and was fenced with 21 round towers. Many parts of it are still entire, including the state hall, which is 130 feet long, 32 broad and 20 high. A suspension bridge was thrown over the river in 1826, and in 1848 another bridge was built by Robert Stephenson for the accommodation of the Chester and Holyhead Railway. It is a wrought-iron tubular bridge on the same principle as the Britannia bridge over the Menai Strait. Con-

way unites with Carnarvon, Bangor, Criccieth, Nevin and Pwllheli in returning one member to Parliament. Curfew is still rung in Conway. Pop. 5,242.

CONWAY, a river of Wales, rising from two head-streams, one in the southeast of the county of Carnarvon and the other in the southwest of the county of Denbigh, which unite about 15 miles south of Conway. At Conway it is half a mile broad at spring tides which rise here 21 to 24 feet. The united stream flows north, separates Carnarvon from Denbighshire, and falls into Beaumaris Bay after a course of from 25 to 30 miles. It is navigable to Llanrwst, or about 10 miles from its mouth. The Conway has been famous for its pearls since Roman times.

CONWAY CABAL, 1777–78, in American history: an intrigue headed by Horatio Gates, Charles Lee, Thomas Mifflin (then quartermaster-general) and James Lovell of Boston (Gates' confidant, and an unsparing contemner of Washington); with Thomas Conway as a tool. The prime object was to displace Washington by Gates; and there were plenty of other ambitions which hoped to reap advancement in the overturn. It gained its momentum from that popular clamor for immediate success in the war. The faction endeavored to prove the superiority of Gates over Washington as commander by contrasting the victories of the former at Saratoga with the almost contemporaneous reverses of the latter at Brandywine and Germantown. In November 1777 the Board of War was reconstituted: Gates was made president, with liberty to serve in the field at will — that is, put over Washington's head with power to supersede him: Mifflin was made a member of the Board of War and shortly afterward Conway was made inspector-general over Washington's emphatic advice to the contrary. A very petty series of letters maligning Washington was circulated, and other minor intrigues resulted. Then Gates undertook to send Lafayette on a senseless expedition to Canada, promising him abundant men and supplies; but he so utterly failed of providing either and the scheme was so disapproved by the public that it pricked the Gates bubble. Conway resigned conditionally; Gates and Mifflin were removed from the Board of War and Gates was assigned to the forts on the Hudson, with emphatic warning to report to Washington. The adherents or helpers of the cabal disclaimed all connection with it, and Conway shortly went to France. Consult Fiske, 'The American Revolution' (Vol. II, Boston 1893).

CONWELL, Russell Herman, American Baptist clergyman, educator and lecturer; b. Worthington, Mass., 15 Feb. 1842; d. Philadelphia, Pa., 6 Dec. 1925. He studied law at the Yale and Albany Law schools, and was an officer in the Federal army in the Civil War. He was immigration officer of Minnesota in Germany in 1867–68; foreign correspondent, the New York *Tribune* and Boston *Traveler,* 1868–70; and practised law in Boston 1870–79. He was ordained to the Baptist ministry in 1879; was pastor of Grace Baptist Church, Philadelphia, 1881–91; and thereafter was pastor of the Baptist Temple. He founded Temple University in 1888 and was its president until his death. He founded the Samaritan Hospital in 1891. He gave his celebrated lecture, "Acres of Diamonds" over 5,000 times. He was a member of the Union League, Manufacturer's Club, New England Society and Yale Alumni. Among the books he published are 'Life of Bayard Taylor' (1888); 'Why the Chinese Emigrate' (1874); 'Woman and the Law' (1875); 'Life of C. H. Spurgeon' (1893); 'Acres of Diamonds' (1888); 'Present Successful Opportunities' (1878); 'Life of James G. Blaine'; 'The New Day' (1902); 'Borrowed Ayes' (1923).

CONY, or **CONEY,** an old name for the rabbit; used also in the English version of the Bible as a translation of a Hebrew word probably meaning the *Hyrax syriacus,* a rabbit-like animal common in Syria and Palestine, inhabiting clefts of rocks.

CONYBEARE, Frederick Cornwallis, English Orientalist: b. 1856; d. England, 1924. He was educated at Tonbridge School and at University College, Oxford, of which he became scholar in 1875 and Fellow in 1881. He was made a Fellow of the British Academy in 1903, an officer of the French Academy in 1906, and honorary doctor of theology at Giessen in 1907. In his special field, Armenian language and literature, he came to be recognized as probably the foremost authority of his time; but he wrote on religion and religious history. His published works include 'Ancient Armenian Texts of Aristotle' (1892); 'The Key of Truth, a Manual of the Paulician Church of Armenia' (1898); 'Roman Catholicism in International Politics' (1901); 'Rituale Armenorum' (1905); 'Old Armenian Texts of Revelation' (1906); 'Myth, Magic and Morals: a Study of Christian Origins' (1909); 'New Testament Criticism' (1910); 'The Historicity of Christ' (1914).

CONYBEARE, kŭn'ĭ-bēr, **John,** English prelate: b. Pinhoe, near Exeter, 31 Jan. 1692; d. Bath, 13 July 1755. He studied at Exeter College, Oxford, received orders, and was curate at Fetcham in 1717. He returned to Oxford in 1718, became successively tutor in his own college, preacher to his majesty at Whitehall, rector of Saint Clement's, Oxford, and in 1730 master of Exeter College. In 1732 he published his celebrated 'Defense of Revealed Religion,' in answer to Tindal's 'Christianity as Old as the Creation.' In that year also he was appointed dean of Christ Church; and in 1750 succeeded Butler as bishop of Bristol.

CONYBEARE, William John, English clergyman: b. England, 1 Aug. 1815; d. Weybridge, Surrey, 1857. He published 'Perversion,' a religious novel (1856); and 'Essays Ecclesiastical and Social,' but is principally known for his joint authorship with Dean Howson of the popular 'The Life and Epistles of Saint Paul' (1851).

CONYERS, kŏn'yĕrz, Ga., city and Rockdale County seat; alt. 909 feet; 31m. SE. of Atlanta; on the Georgia and the Milstead railroads. Although situated in a granite quarrying area, Conyers is essentially agricultural. Cows and chickens are raised here and cotton, corn and garden truck grown. Pop. (1940) 1,619.

CONZE, kônt'se, **Alexander Christian Leopold,** German archæologist: b. Hanover 1831; d. 1914. He received his education at Göttingen and Berlin. From 1863 to 1869 he was professor of archæology at Halle, from 1869 to 1877 at

Vienna, and at Berlin from 1877 to 1887. He was made director of the Berlin Museum and in 1887 became general secretary of the German Archæological Institute. His published works include 'Reise auf den Inseln des thrazischen Meeres' (1860); 'Archäologische Untersuchungen in Samothrake' (2 vols., Vienna 1875–80); 'Beiträge zur Geschichte der griechischen Plastik' (2d ed., Halle 1869); 'Die Ergebnisse der Ausgrabungen zu Pergamon' (Berlin 1880–88); 'Die Arbeiten zu Pergamon, 1886–98' (Athens 1899); 'Die Kleinfunde aus Pergamon' (Berlin 1902).

COOCH BEHAR, kooch bā-här', or **KUCH BEHAR,** India, a native state and in political relation with the government of Bengal. It forms a level plain of triangular shape, intersected by numerous rivers which make a great part of it almost hopelessly waterlogged, and is entirely surrounded by British territory. The greater portion of the soil is fertile and well cultivated. Rice, jute and tobacco are the principal crops. The mean annual temperature is 78 degrees, and the rainfall 123 inches. It was at one time a part of the ancient kingdom of Kamarapu. British connection began in 1772. The chief town, Cooch Behar (pop. 11,000), contains some handsome public buildings and a splendid new palace of the Maharajah, and has a population of 9,535. Area of state 1,319 square miles. Pop. 593,000.

COODIES, The, in the political history of the United States, a nickname applied to those members of the Federalist party in New York who favored the War of 1812. It was adopted from the fictitious name, Abimelech Coody, assumed by the leader of the faction, Gulian C. Verplanck (q.v.) when writing in the public prints. Consult Hammond, 'The History of Political Parties in the State of New York' (4th ed., Cooperstown 1846).

COOK, Albert John, American naturalist: b. Owosso, Mich., 30 Aug. 1842; d. 29 Sept. 1916; graduated at Michigan Agricultural College 1862; professor of zoology and entomology there 1869–93, when he became professor of zoology in Pomona College, Claremont, Cal. In 1911 he was appointed State commissioner of horticulture for California. He was one of the first to make kerosene emulsion (1877), and to advocate and demonstrate the use of the arsenites as a specific against the codling moth (1880). He published 'Injurious Insects of Michigan' (1873); 'Manual of the Apiary' (1876; 14th ed., 1886); 'Silo and Silage'; 'Maple Sugar and the Sugar Bush'; 'Birds of Michigan'; 'California Citrus Culture' (1913).

COOK, Albert Stanburrough, American scholar: b. Montville, N. J., 6 March 1853. He was graduated at Rutgers College 1872, and studied at Göttingen and Leipzig 1877–78, London and Jena 1881–82. He was professor of English in the University of California 1882–89, when he became professor of the same in Yale University. He organized the department of English at the Johns Hopkins University (1879–81); brought the University of California into closer relations with the high schools of the State (1884–89); translated into English the first thoroughly scientific grammar of Old English; established a new standard of editing for Old English texts; laid a firm basis for the study of the Old Northumbrian dialect, the modern Scotch and Northern English; was instrumental in having the study of English texts, as distinct from reading and composition, made a national requirement for admission to college 1894; he specialized on the study of the Bible in English; edited books on the criticism of poetry; was the first to edit a volume of Ginn's Athenæum and Albion series and of Heath's *Belles Lettres* series, Old English division; founded the Concordance Society in 1906, of which he was president until his death, and edited 'Concordance to Gray' (1908), 'Concordance to Beowulf' (1910); was president of the Modern Language Association of America 1897; edited a series of 70 volumes, 'Yale Studies in English'; established a probable date for the two chief Runic monuments of Great Britain ('The Date of the Ruthwell and Bewcastle Crosses,' 1912); published a 'Literary Middle English Reader' (1915); a translation of Sievers' 'Old English Grammar' (1885). His publications further include 'The Phonological Investigation of Old English' (1888); 'The Bible and English Prose Style' (1892); 'The Art of Poetry' (1892); 'First Book in Old English' (1894; 3d ed., 1903); 'The Artistic Ordering of Life' (1898); 'Biblical Quotations in Old English Prose Writers' (1904, 1913); 'Higher Study of English' (1906); 'Concordance to Beowulf' (1910); 'Aims in the Teaching of English Literature' (1925); 'Cynewulf's Part in Our Beowulf' (1925). He died, New Haven, Conn., Sept. 1927.

COOK, Sir **Edward Tyas,** English journalist: b. Brighton, 12 May 1857; d. London, England, 2 Oct. 1919. He was educated at Winchester College and Oxford, and was subsequently editor of the *Pall Mall Gazette,* 'Westminster Gazette' and the London *Daily News.* He published 'Popular Handbook to the National Gallery'; 'Studies in Ruskin'; 'Popular Handbook to the Tate Gallery'; 'Life of Ruskin' (1911); 'Homes and Haunts of Ruskin' (1912); 'Life of Florence Nightingale' (1913). He was knighted in 1912.

COOK, Eliza, English writer of verse: b. Southwark 1818; d. Wimbledon, Surrey, 24 Sept. 1889. She began at an early age to contribute articles to various periodicals, and her first volume of verse, which appeared in 1840, was very successful. In 1849 she published 'Eliza Cook's Journal,' which appeared weekly until 1854. She published 'New Echoes, and other Poems' (1864), and in the same year received a pension from the Civil List. By their simplicity of theme and treatment her poems obtained a large measure of popularity in England and America. Her most familiar poem is 'The Old Arm Chair.' A complete edition of her poetical works appeared in London in 1870 and in New York in 1882.

COOK, Francis Augustus, American naval officer: b. Northampton, Mass., 10 May 1843; d. 8 Oct. 1916; graduated, Annapolis 1863, and served for two years with Farragut in the West Gulf squadron. He became lieutenant-commander 1868; commander 1881 and captain in 1896. During the Spanish-American War he commanded the *Brooklyn,* the flagship of Commodore Schley's flying squadron, which took so conspicuous a part in the battle of Santiago, 3 July 1898, when Cervera's fleet was destroyed. He was relieved of sea duty after the war and

received an appointment to the United States Naval Examining Board. He was retired in 1903.

COOK, Frederick Albert, American physician and explorer: b. Calicoon Depot, Sullivan County, N. Y., 10 June 1865; d. New Rochelle, N. Y., 5 Aug. 1940. He was the son of Dr. Theodore A. Koch, a German physician who came to the United States in 1853, and changed the family name to Cook in 1860. After attending the public schools in Brooklyn, he was graduated from the Medical School of New York University, 1890, with the degree of M.D. He was surgeon of the Peary Arctic expedition, 1891–92, and of the Belgian Antarctic expedition, 1897–99. He led several expeditions into the Arctic and on 1 Sept. 1909, he wired the Royal Observatory at Brussels that he had on 21 April 1908 discovered the North Pole. The announcement was hailed with great enthusiasm in certain quarters, though viewed with skepticism in others. The newspapers stated that «Cook had won the race with Peary,» who is actually credited with having discovered the North Pole on 6 April 1909. Cook, who was accompanied only by two Eskimos, professed to have found 30,000 square miles of land in the vicinity of the pole which he claimed for the United States.

Upon his return from what he called «the Pole» in 1909, honors were showered upon him in Copenhagen, Denmark, where he received a royal welcome and was awarded the honorary degree of Doctor of Science by the University of Copenhagen. On his arrival in New York, 21 Sept. 1909 he was welcomed as a hero and began making large sums of money by writing and lecturing on his professed discovery of the North Pole. There was a growing skepticism of his claims, however, and he was discredited in scientific circles when on 21 December following the University of Copenhagen announced officially that the data submitted by Doctor Cook failed to substantiate his claims and canceled the degree that it had conferred upon him. Part of this data was entirely fictitious, according to affidavits of the two men whom Cook had hired to prepare it. On 24 Dec. 1909 Cook was expelled from the Explorers Club of New York because evidence had been adduced that he had failed to ascend Mount McKinley during his 1906 expedition, as claimed, and later he was expelled from the Arctic Club. For a time Cook disappeared, but showed up again to resume writing and lecturing. In 1913–14 he lectured in England. The sale of his book, 'My Attainment of the Pole' (1909, 3d ed. 1913) was very large. In November 1923 he was sentenced by the United States Court at Fort Worth, Texas, to 14 years imprisonment, and a fine of $12,000 for violation of the postal laws, in connection with an oil swindle. He was released from prison 8 May 1930 on parole, and granted an unconditional pardon by President Roosevelt 18 May 1940. Author: 'To the Top of the Continent' (1908); 'My Attainment of the Pole' (1909).

COOK, James, English navigator: b. Marton, North Riding of Yorkshire, 27 Oct. 1728; d. Hawaii, 14 Feb. 1779. After a meager education he was apprenticed to a shopkeeper at Staithes, a small town on the sea-coast. Here he acquired a taste for the occupation of a sailor, and at the commencement of the French War in 1755 entered the royal navy. In 1759 he was made master of the *Mercury,* which belonged to the squadron sent against Quebec, and performed the hazardous service of taking soundings in the river Saint Lawrence opposite the French encampment. He also made a chart of the river Saint Lawrence below Quebec in a very satisfactory manner. The charts and observations which he made of the coasts of Newfoundland and Labrador, published in 1776–78 and distinguished for their accuracy, introduced him to the notice of the Royal Society.

This organization appointed him in 1768 to the command of a vessel destined to convey to the Pacific Ocean persons employed by government to make observations on the transit of Venus. He left Plymouth on 26 Aug. 1768, touched at Madeira and Rio de Janeiro and doubled Cape Horn. The transit of Venus, 3 June 1769, was advantageously observed at Tahiti; the neighboring islands were explored, and Cook then sailed for New Zealand. Six months were employed in examining the shores of the islands; after which he took his departure for Australia, the eastern coast of which he attentively surveyed as well as of New South Wales. On his return in 1771 he was raised to the rank of master and commander in the navy. An account of the voyage, drawn up by Dr. Hawkesworth, was speedily published, and a second expedition was planned to explore the Antarctic regions.

On this occasion two ships were employed the *Resolution,* of which Captain Cook had the command, and the *Adventure,* under Captain Furneaux. After proceeding as far south as the latitude of 71 degrees, where a barrier of ice opposed any further progress, discovering the island of New Georgia in lat. 54° S., and visiting Tahiti and other places, encircling over 20,000 leagues, Captain Cook returned to Great Britain in 1775. The captain had taken such excellent precautions for his crew that only one man died. He communicated to the Royal Society a paper describing the regulations and remedies which he had adopted and was chosen a fellow of that body, and his experiments were rewarded by the Copleian gold medal. Government rewarded him with the rank of post-captain in the navy, and the appointment of captain in Greenwich Hospital. The narrative of this voyage was drawn up by Captain Cook himself, and was published at London in 1777. In July 1776 he sailed on an expedition to ascertain whether any communication existed between the Atlantic and Pacific oceans in the Arctic regions. In this voyage he again commanded the *Resolution,* which was accompanied by the *Discovery,* and explored a considerable extent of the western coast of North America. He also discovered the Sandwich Islands, and to Hawaii, one of this group, he returned from his American survey to pass the winter of 1778. In February Captain Cook sailed for Kamchatka, but was compelled by an accident to put back to Hawaii. A boat having been stolen by one of the islanders, the captain went on shore to seize the king of Hawaii, and keep him as a hostage till the boat was restored. The people, however, were not disposed to submit to this insult; their resistance brought on hostilities, and in attempting to reach his boat Captain Cook and some of his force were slain, 14 Feb. 1779, when he went ashore armed, to recover his property. A complete ac-

count of this third voyage appeared in 1784. The first two volumes were by Captain Cook himself, and the third by Capt. James King. A medal in commemoration of him was struck by order of the Royal Society; his eulogy was pronounced in the Florentine Academy and was made a prize subject by one of the French scientific societies. Consult Kippis, 'Life of Captain James Cook' (1788); Besant, 'Captain Cook' (1890); Wharton, 'Captain Cook's Journal During His First Voyage Round the World' (1897); Synge, 'Captain Cook's Voyages' (1897); Kitson, 'Captain James Cook' (1907); Mitton, G. E., 'Captain Cook' (1927).

COOK, John, Canadian clergyman and educator: b. Sanquhar, Scotland, 1805; d. Kingston, Ontario 1892. He was educated at Edinburgh University, was ordained to the Presbyterian ministry in 1835, and came to Canada in 1836, settling at Quebec. He aided in founding Queen's University, Kingston, and was acting principal there in 1857–60 and first chancellor 1877–80. He was also one of the founders of Morvin College, Quebec, in 1862, and became its first principal. He actively supported Presbyterian union in Canada and in 1875 was the moderator of the first general assembly.

COOK, John Francis, American negro educator: b. about 1785; d. Washington, D. C., 1855. In 1834 he became head of the Columbian Institute, a free school for negro children. Cook stands forth the most conspicuous figure of his race during the first half of the 19th century. His leadership was manifested both in religious matters and in secular affairs. He was one of the organizers of Union Bethel Church in 1838; was organizer and first pastor in 1841 of the Fifteenth Street Presbyterian Church; was one of the charter members of United Friendship Lodge of Odd Fellows. At his death the mantle of education fell to his two sons, who had gained their experience as his assistants at the Columbian Institute.

COOK, John Francis, American negro educator and civil administrator: b. Washington, D. C., 21 Sept. 1833; d. 1910. His early years were spent without special incident. After teaching for some years in the school established by his father, John Francis Cook, Sr. (q.v.), he taught for a brief period in New Orleans and until the outbreak of the Civil War. In 1867 he accepted a clerkship in the office of the collector of taxes in his native city. The next year he became a member of the board of aldermen and in 1868 was elected register of the city. In 1874 he was nominated to the collectorship of taxes by President Grant and confirmed by the Senate, a position held by him through the administrations of Grant, Hayes, Garfield and Arthur, until the accession of the Democratic party caused his resignation. In 1906 he was appointed a member of the local board of education. He also served as trustee of Howard University for 35 years.

COOK, Joseph, American lecturer and author: b. Ticonderoga, N. Y., 26 Jan. 1838; d. there, 24 June 1901. He was graduated at Harvard and Andover Theological Seminary, and after three years' preaching went to Europe in 1871, where he studied in Germany, and made a tour of the Mediterranean countries. In 1873 he began a series of «Monday Lectures» in Boston, which, endeavoring to harmonize science and religion, and discussing social and political questions, became very popular; in 1880 he began an extended lecturing tour around the world. In 1883 he returned to Boston and resumed his Monday lectures. In 1888 he founded a religious monthly called *Our Day*. Besides his lectures, he published a number of works on such subjects as 'Biology' (1877); 'Transcendentalism' (1877); 'Marriage' (1878); 'Heredity' (1879); 'Labor' (1880); 'Socialism' (1880); 'Occident' (1884); 'Orient' (1886); 'The Higher Levels of Arbitration' (1900); 'New Defenses of the Lord's Day' (1900).

COOK, Melville Thurston, American botanist: b. Coffeen, Ill., 20 Sept. 1869. He was educated at De Pauw and Leland Stanford Junior universities, and took post-graduate work at the universities of Chicago and Ohio. In 1894–95 he was principal of the Vandalia (Ill.) high school, in 1895–97 instructor, and in 1897–1904 professor of biology at De Pauw University; chief, department of plant pathology and economic entomology, Estación Central Agronómica, Santiago de las Vegas, Cuba, 1904–06; plant pathologist, Delaware agricultural experiment station, Newark, N. J., 1907–11; professor of plant pathology, Rutgers College and State plant pathologist of New Jersey, 1911–23; plant pathologist, Insular Experiment Station, Rio Piedras, P. R. after 1923. He published 'Diseases of Tropical Plants' (1912) 'College Botany' (1920).

COOK, Orator Fuller, American botanist: b. Clyde, N. Y., 28 May 1867. He was educated at Syracuse University, where he was in charge of the biology department in 1890–91. As agent of the New York Colonization Society he made explorations and investigations in Liberia in 1891–97, and he also served as professor of natural sciences in Liberia College during this same period and as president of the institution in 1896–97. In 1898 he became custodian and assistant curator of the United States National Museum. He had charge of plant importation by the United States Department of Agriculture from 1898 to 1900, when he took up the investigation of tropical agriculture. In 1904 he became professor of botany at George Washington University. In 1915 he accompanied the Bingham expedition to Peru and, in 1922, the Carnegie Institution expedition to study Maya civilization. He is author of various articles and reports on colonization, tropical agriculture, botany, zoology and evolution.

COOK, Stanley Arthur, English Orientalist: b. King's Lynn, 12 April 1873. He was educated at Gonville and Caius College, Cambridge, of which he became fellow and lecturer in Hebrew and Syriac. In 1896–1903 he was on the editorial staff of the 'Encyclopædia Biblica'; in 1902 he became editor for the Palestine Exploration Fund; department editor for Biblical subjects, 14th edition, the 'Encyclopædia Britannica'; co-editor, Cambridge Ancient History. He contributed to the *Jewish Quarterly*, the *Expositor*, etc., and published 'Glossary of Aramaic Inscriptions' (1898); 'The Laws of Moses and the Code of Hammurabi' (1903); 'Critical Notes on Old Testa-

ment History' (1907); 'Religion of Ancient Palestine' (1908); 'I Esdras' (1912); 'The Study of Religions' (1914); 'The Religion of Ancient Palestine in the Light of Archæology' (1930).

COOK, Sir Theodore Andrea, English journalist and author: b. Exmouth, 28 May 1867; d. 16 Sept. 1928. He was educated at Wadham College, Oxford, and was on the editorial staff of the *Saint Jame's Gazette,* 1897–1900, and became editor-in-chief of *The Field* in 1910. He published 'Old Touraine'; 'Rouen' in 'Mediæval Towns Series'; 'Tobogganing at Saint Moritz'; 'A History of the English Turf'; 'An Anthology of Humorous Verse'; 'The Spiral in Nature and Art'; 'Turner's Water-Colors in the National Gallery'; 'Old Provence'; 'Twenty-five Great Houses of France'; 'The Germans by Themselves'; 'Character and Sportsmanship.'

COOK, Thomas, English excursion promoter: b. Melbourne, Derbyshire, 22 Nov. 1808; d. 19 July 1892. In the earlier portion of his career he was prominently identified with the temperance cause. Later he devoted himself to the work for which he became famous. On 5 July 1841 he began an excursion train between Leicester and Loughborough on the Midland Railway, England. This was the first publicly advertised excursion train in England. From this small beginning the enormous business of Thomas Cook & Son, Managers of Tours and Excursions (known as "Cook's Excursions") was subsequently evolved. To John Mason Cook, son of the founder (b. January 1834; d. 4 March 1899), the present scope of the business is mainly due. The existing firm is composed of the three grandsons of the founder. To such an extent has the "Cook's Excursion" business developed that the company now has agencies all over the globe, the head office for the United States being in New York.

COOK, Walter, American architect: b. New York, 23 July 1846; d. 26 March 1916; educated, Harvard University and studied architecture at the Royal Polytechnic School, Munich, and the École des Beaux-Arts, Paris. In 1877 he returned to New York, becoming in succession a member of the firm of Babb, Cook and Willard; Babb, Cook and Welch; and Cook and Welch. He was a member of the jury for the New York Public Library and for the University of California, became consulting architect for the board of estimate and apportionment, New York, and was a member of the New York art commission 1905–07. Among the buildings designed wholly or in part by him are the DeVinne Press building, office buildings for the New York Life Insurance Company, a residence for Andrew Carnegie, the Choir School at the cathedral of Saint John the Divine, the stadium and other buildings at the Pan-American Exposition, and a number of branch buildings for the New York Public Library. He was a member of the National Academy of Design and chevalier of the Legion of Honor.

COOK, William Wilson, American lawyer: b. Hillsdale, Mich., 16 April 1858; d. Portchester, N. Y., 4 June 1930; A.B., University of Michigan, 1880; LL.B. 1882. He was engaged in the practice of corporation law in New York until 1921. He has written 'Treatise on the Law of Stock and Stockholders as Applicable to Railroad, Banking, Insurance, etc., Corporations'; 'Trusts: Their Character, Legality and Mode of Organization'; 'Principle of Corporation Law'; 'American Institutions and Their Preservation.'

COOK, Mount, the highest peak of Australasia; is one of the southern Alps near the centre of the range, on the west side of the South Island of New Zealand. It is 12,349 feet high, is covered with perpetual snow (the snowline being 3,500 feet lower than in Switzerland), is difficult of access, and was scaled for the first time by the Rev. W. S. Green on 2 March 1882.

COOK INLET, Alaska, bay of the north Pacific Ocean, between the Alaskan and Kenai peninsulas, in lat. 59° and 61° 20′ N. and long. 149° and 154° W. In shape long, narrow and crooked, its length is about 200 miles and its greatest breadth 60 miles. Sudden storms, fogs and tidal rips, due to high tides along the broken coast line, make navigation at the northern extremity somewhat dangerous. From November to May the northern part is locked in ice. It contains several islands, Augustine Island, with its volcano, Mount Saint Augustine, in violent eruption during 1883, being the largest. The coast scenery is grand, comprising active volcanoes, snow-clad mountains, glaciers and green hills. It was explored in 1778 by the navigator whose name it bears, in the hope of finding a passage to the Arctic Sea. The chief tributaries are the Susitna and Matanuska rivers. Coal is found on its shores, along which are the towns of Anchorage at the head and on the Alaska Railroad, and Seldovia near the mouth, both with steamboat connections.

COOK ISLANDS, New Zealand, archipelago of small islands in Polynesia, consisting of the islands of Raratonga, Mangaia, Atiu, Aitutaki, Mauke, Mitiaro and the Hervey group. They lie between 8° and 23° S. lat., 157° and 170° W. long.; area 142 sq. m. The soil is generally fertile but water is scarce. The chief products are copra, coffee, pearl-shell, fruit, hats and caps and lime-juice. The trade of Cook, Niue (Savage), etc., for 1928 was imports £136,276, including £95,914 from New Zealand; exports £153,989, including £112,817 to New Zealand. The inhabitants are Polynesians of the Tongafiti migration, and are all converts to Christianity. The islands were discovered by James Cook in 1773–77; became a British protectorate in 1888, and in 1901 were annexed to the Dominion of New Zealand, together with Niue and other South Pacific islands. Laws have been made since 1890 by a general legislature, and are administered by an executive council of which the Arikis, or native chiefs, are members. At Raratonga and Niue are resident commissioners. The annual death-rate often exceeds the birth-rate of the islands. Pop. of Cook Islands, Niue, etc., 13,877; area, 280 square miles.

COOK STRAIT, New Zealand, passage which separates North Island and South Island. Its greatest width is 90 miles. It was discovered by Captain Cook on his first voyage in 1769.

COOKE, George Frederick, English actor: b. Westminster, 17 April 1756; d. New York, 26 Feb. 1811. He made his first public appearance at Brentford in 1776; and in the period

between 1784 and 1800 became very popular in the English provinces and in Ireland, attaining a front rank in his profession. From 1801 to 1810 he played at Covent Garden both in comedy and in tragedy, and rivaled Kemble in the public favor. His best characters were Richard, Shylock, Iago, Sir Giles Overreach and Sir Pertinax MacSycophant. In 1810 he visited the United States and appeared before enthusiastic audiences in the chief cities. A monument marks his grave in Saint Paul's churchyard in New York city, erected in 1821 by Edmund Kean, who regarded Cooke as the greatest of actors. Consult Dunlap, 'Memoirs of Cooke' (London 1813).

COOKE, George Willis, American Unitarian clergyman and author: b. Comstock, Mich., 23 April 1848; d. 30 Apr. 1923; educated Olivet College, Michigan, studied for the Unitarian ministry at Meadville Theological School; ordained in 1872. He afterward held Unitarian pastorates in Wisconsin, Michigan, Indiana and Massachusetts. After 1899 he devoted his time principally to lecturing and writing. Besides contributing much to the periodical press, including editorials to the *Christian Socialist* (he became a Socialist in 1902), he published 'Ralph Waldo Emerson, his Life and Writings' (1881); 'Life of George Eliot' (1883); 'Poets and Problems'; 'The Clapboard Trees Parish, Dedham: a History' (1887); 'A Guide Book to the Poetic and Dramatic Works of Robert Browning' (1891); 'The Spiritual Life' (1893); 'Biography of John Sullivan Dwight' (1898); 'History of Unitarianism in America' (1903); Notes to the Riverside edition of the Works of Robert Browning (1889); 'An Historical and Biographical Introduction to the Dial' (1902); 'The Poets of Transcendentalism' (1902); 'Bibliographies of Lowell and Emerson' (1907); 'Woman in the Progress of Civilization' (1909); edited three volumes of Theodore Parker's Complete Works (1910).

COOKE, Grace MacGowan, American novelist: b. Grand Rapids, Ohio, 11 Sept. 1863. In 1897–98 she was president of the Tennessee Woman's Press Club. Her publications include 'Mistress Joy,' with Annie Booth McKinney (1901); 'Return: A Story of the Sea Islands,' with Alice MacGowan (1903); 'Huldah' (1904); 'A Gourd Fiddle' (1904); 'The Grapple' (1905); 'Their First Formal Call' (1906); 'Son Riley Rabbit and Little Girl' (1907); 'The Power and the Glory' (1910); 'The Doings of the Dollivers' (1910); 'The Joy Bringer' (1912); 'William and Bill' (1914); 'Sonny Bunny Rabbit' (1915); 'The Fortunes of John Hawk' (1928); co-author, 'Straight Road' (1917); and 'Wild Apples' (1918).

COOKE, Jay, American capitalist, known as the "Financier of the Rebellion": b. Sandusky, Ohio, 10 Aug. 1821; d. Ogontz, Pa., 16 Feb. 1905. He was educated in private schools. At the age of 13 he had entered mercantile life as a clerk in a Sandusky store, there displaying unusual ability as a bookkeeper. In 1835 he went to Saint Louis to engage in mercantile business. In 1838 he entered the banking house of E. W. Clark & Company in Philadelphia, and so rapidly mastered the intricacies of finance that before he became of age he was given power of attorney for the firm. Upon his retirement from that firm he was engaged in a general banking business until 1861, when he united with his brother-in-law under the name of Jay Cooke & Company. From 1861–65 his house acted as agent for the government in floating the Civil War bond issues to the extent of $2,500,000,000, including the 5–20 loan of $515,000,000 (February 1862), the 10–40 loan of $200,000,000 (March 1864), the 7–30 loan of $829,992,500 (June 1864 to March 1865), and others. These services he rendered to the nation for so small a commission there was practically no profit. A long period of successful operations followed the war, and then the firm became fiscal agents of the Northern Pacific Railway Company, advancing large sums of money on its bonds, but in the financial panic of 1873, being unable to realize a sufficient amount on the bonds to tide them over the trouble, on 18 September suspended business and eventually went into bankruptcy. The value of the bonds afterward greatly increased. Mr. Cooke not only regained his fortune, but paid his creditors both principal and interest, and the firm continued successfully. Consult Oberholtzer, E. P., 'Jay Cooke, Financier of the Civil War' (Philadelphia 1908).

COOKE, Josiah Parsons, American chemist: b. Boston, 1827; d. 1894. He was graduated at Harvard in 1848, and soon afterward was appointed to the chair of chemistry and mineralogy there. In this capacity he stimulated the study of chemistry at collegiate institutions, urging laboratory instruction, which before his time had not been introduced into the undergraduate course of American colleges. He introduced his pupil Theodore William Richards to the study of atomic weights — a subject to which the latter made many signal contributions. The joint communication, by Cooke and Richards, on the relative values of the atomic weights of hydrogen and oxygen, was published in the 'Proceedings of the American Academy of Arts and Sciences' for 1887. Cooke's other publications include 'Chemical Problems and Reactions' (1853); 'Elements of Chemical Physics' (1860; 4th ed., 1886); 'First Principles of Chemical Philosophy' (1868; rev. ed., 1882); 'The New Chemistry' (1872, 1884); 'Michigan: a History of Governments' (1885; rev. ed., 1905); 'The Credentials of Science the Warrant of Faith' (1888).

COOKE, Mordecai Cubitt, English botanist: b. Horning, Norfolk, 1825; d. 1912. When a boy he was successively a draper's assistant, clerk in a law office and later a school teacher. He secured a position in the Indian Museum in 1860, and was transferred thence to the Kew Botanical Gardens in 1880. In 1903 he was awarded the Victoria medal of honor by the Royal Horticultural Society, and the Linnæan gold medal by the Linnæan Society. He published over 40 volumes, several of which deal with fungi, including 'Manual of Botanic Terms' (1862); 'Handbook of British Fungi' (1874); 'Mycographia' (6 vols., 1879); 'Illustrations of British Fungi' (8 vols., 1881); 'Introduction to the Study of Fungi' (1895); 'Mushrooms, Edible and Poisonous' (1903); 'Fungoid Pests of the Flower Gardens' (1906); 'Manual of Structural Botany' (1907).

COOKE, Philip Saint George, American military officer: b. near Leesburg, Va., 13 June 1809; d. Detroit, Mich., 20 March 1895. He was graduated at West Point in 1827 and rose to the rank of brigadier-general. He was on the frontier for several years, and took part in the Black Hawk War of 1832. In the Mexican War he was in California in command of a battalion of Missouri volunteers and later commanded a regiment in the city of Mexico. After 1849 he was again on the frontier, took part in several expeditions against the Indians, commanded the Utah expedition of 1857–58 and was commander of the Department of Utah in 1860–61. In the Civil War he sided with the Union and greatly distinguished himself in the Peninsular campaign. He was brevetted major-general at the close of the war, commanded the Department of the Platte in 1866–67, the Department of the Cumberland in 1869–70, and the Department of the Lakes, 1870–73, when he retired. He was the author of works on tactics and of 'Scenes and Adventures in the Army' (1856); 'Conquest of New Mexico and California' (1878); 'New Cavalry Tactics' (1884).

COOKE, Richard Joseph, American Methodist Episcopal bishop: b. New York, 31 Jan. 1853. He was graduated at East Tennessee Wesleyan University in 1880. He entered the ministry in 1873, became professor of New Testament exegesis and historical theology in Grant University, with which institution he was connected until 1912. From 1891 to 1912 he was editor of the *Methodist Advocate Journal,* and book editor of the Methodist Episcopal Church. In 1912 he was chosen bishop of the Church. He was fraternal delegate from the Methodist Episcopal Church to the British and Irish Wesleyan conference, England and Ireland 1906. He published 'Doctrine of the Resurrection' (1884); 'Reasons for Church Creed' (1888); 'Christianity and Childhood' (1891); 'The Historic Episcopate' (1896); 'History of Ritual of M. E. Church' (1900); 'Christ and the Critics' (1898); 'Digest of Judicial Decisions of the General Conference of the M. E. Church'; 'Incarnation and Recent Criticism' (1907); 'Freedom of Thought in Religious Teachings' (1913); 'Religion under the Soviets.' He died, Athens, Tenn., 25 Dec. 1931.

COOKE, Rose (Terry), American poet and story writer: b. West Hartford, Conn., 17 Feb. 1827; d. Pittsfield, Mass., 18 July 1892. She married Rollin H. Cooke in 1873. Her complete poems were published in 1888, 'The Two Villages' being her best known poem. Her short stories treat of New England rural life, her most acceptable work appearing originally in the *Atlantic Monthly* and other periodicals. Her published books include 'Poems' (1860); 'Happy Dodd' (1878); 'Somebody's Neighbors' (1881); 'The Sphinx's Children and Other People's' (1886); Complete Poems' (1888); 'Steadfast,' a novel (1889); 'Huckleberries,' a collection of short stories (1891).

COOKE, Sir William Fothergill, English electrician: b. Ealing, Middlesex, 1806; d. 25 June 1879. He served in the Indian army from 1826 to 1831; and, after studying medicine at Paris and Heidelberg, abandoned this for telegraphy, and in 1837 entered into partnership with Professor Wheatstone. After experiments on various railway lines, they patented the single needle apparatus in 1845. A dispute then ensued between the partners as to the part played by each in the achievement. In 1846 Cooke formed a company, which paid $600,000 for the partners' earlier patents. Wheatstone was knighted in 1868 and Cooke in 1869.

COOKERY, the art of preparing food for eating. The savage does little or no cooking; he lives on roots, fruits, insects and raw flesh, and when he cannot procure food, he twists his belt tighter and tighter; the barbarian makes a fire and hunts and fishes, but still eats much of his food raw, or with the slight disintegration of fibre given it by the motion of his body as he carries the food on his steed. Neither cares he for variety, nor has any purpose in eating other than to satisfy hunger. With the development of agriculture came an increase in food supplies, in the use of fire in cooking and an advance in civilization; and with the development in man's social nature, eating ceased to be a mere grabbing game, and food was shared with friends,—and strangers also, for there were no public inns,—as an evidence of good will. Later, feasting was a part of all hospitality, and banquets in honor of the gods, of victory, or some special event, came to be considered the highest form of social physical enjoyment. As the ancients in times of prosperity sought the rarest foods (500 nightingales' tongues were often made into one pie), and served them in the most costly manner (whole cities being ruined, it is said, where Xerxes was entertained for two meals), so history repeats itself, and some modern hosts spare no labor or expense in setting before their guests the most unique concoction their chef can prepare, as the highest expression of good will. But they often have no concern as to the nutritive effect of their offering. The thoughtful person feels that extravagant cooking and riotous feasting are not necessary to true hospitality, nor to the genuine enjoyment of food. He has learned that the true reasons for cooking food are:

First, to have the time and energy needed to digest and assimilate unprepared food, to use in getting a living while developing his mental and moral nature.

Second, to facilitate mastication and digestion, by softening hard and tough substances, changing starch into dextrin, sugar into caramel and connective tissue into gelatin, developing improved flavors and odors, and having at least a part of the food warm.

Third, to destroy parasites and disease germs.

Fourth, to keep foods which are perishable that he may enjoy them when out of season.

The cooking of food includes several important processes, not always considered, some of which call for the highest degree of intelligence; but too often cooking is regarded merely as a form of manual labor. Taking these in their natural order we have:

Selection.—This was once a question of mere environment; food nearest at hand being the "Hobson's choice" of the savage, as it now is of the very poor in

many lands. Climate and non-intercourse with other nations limit choice, as invasion, travel and increased trading facilities extend it. From the limited, but not always scanty fare of the Pilgrims, to the cosmopolitan markets of the present day, is a wonderful advance, and the modern American often yields unwisely to their temptations. Appetite guides us safely in this choice of material, when it has not been impaired by too great indulgence in improper food. To select from this vast supply, food sound in texture, free from adulteration, seasonable, not exorbitant in price, adopted to individual need, and suitable in quantity, needs no small amount of judgment in the buyer, who often must also be the cook.

Separation.— The removal of the inedible from the edible portions of food is important, for the thoroughness with which it is done has much to do with making food palatable. Perhaps in no other part of the work has there been greater improvement over the primitive methods, as man's idea of what is inedible takes him farther and farther away from the savage, some of whose methods are too repulsive to bear allusion. Our forbears were entertained before the feast by the slaughtering of animals in their presence, but now the refined taste is offended by the sight of a fowl dressed for the table in his discarded feathers; or a bit of hull in a supposed-to-be coreless apple, or food served in inedible scooped-out skins.

Combination.— The union of various materials often produces a more palatable food than any one would give alone. Association, custom and appetite have much to do with deciding whether certain combinations are harmonious or otherwise. Saffron, tansy, asafetida, decayed fish powder and hosts of other strange flavorings do not appeal to us, although highly prized by other nations. Pies, supposed to be filled with delectable compounds, but out of which dwarfs sprang and danced, and blackbirds sang, pleased our ancestors; and surprise is still a pleasant element in cookery. But it is not pleasant to find the biscuit which was supposed to be sweet with the nutty flavor of the wheat redolent with alkali.

Literature is replete with legends of the accidental discovery of the improved flavor found in a bit of the forbidden flesh on the altar, of fish rescued from burning seaweed, of bread made lighter with a portion of left-over dough, and many others which led to new ways of preparing food. The most fanciful legend seems credible when we remember the many times in one's own experience when accident or necessity has led to new combinations. Scientific proportion, correct measurement, thorough mixing and sufficient judgment to allow for the "total depravity of inanimate things" are needed to ensure uniform results. So to blend materials that they will develop "what ingenious cooks the relish call" is the fundamental principle of cookery, for "all foods are tasteless till that makes them good." It is the undesirable combinations of the odors from the different foods in the ovens and kitchens of many hotels and restaurants that makes the unsatisfied boarder long for home cooking.

The Belgians, Swiss and Austrians are said to have best acquired the art of retaining in a high degree in each food its full essence, aroma and properties, so that each dish has no odor or flavor from another. It is said one of the Roman epicures had a separate cook and separate kitchen for each dish.

Too much time and thought are given to the making of new combinations merely to gratify the desire to excel one's neighbors in one's luncheon. This causes great nervous strain and physical fatigue, and imposes upon the guests a deal of unnecessary work for their digestive organs in the undoing of these combinations.

Manipulation.— For the manual part of cookery, tools and utensils are needed, which if wisely selected will not oblige one to say with Telemachus,

> Lend me, I pray you, the sauce pans
> In which you boiled your beans.— *Timocles.*

That cook is fortunate who has the strength and endurance needed for the back-and arm-aching parts of the work, and still more fortunate if she possesses the deftness of hand and keen sense perception of the culinary artist; for we cook by the senses of touch, smell and hearing, as truly as by sight and taste. And those for whom she cooks are happy indeed if she knows how to apply heat (see *Methods*) in the way that food will yield the greatest amount of nutriment in the shape best fitted for the body to assimilate it, as otherwise much food will be wasted in the cooking and wasted in the body.

Decoration.— This is the last step in the manual part of cookery, but an important one, for "the imagination should be fed when we feed the body, they should both sit at the same table." Those who labor with the larger muscles are usually sufficiently hungry to eat whatever is clean and wholesome; but the non-hungry person, or one who works with the small muscles of the hands or eyes, needs the stimulus which the senses of sight, smell and taste send to the stomach, to arouse his sense of hunger. This class of persons increases as civilization advances. There are some foods which if one ate them blindfolded would satisfy the mouth and the stomach would not demur. The nose rebels at Camembert, but the mouth approves. The eye should not be pleased and the tongue offended, but all these "gate tenders of the stomach" should agree in approval, if we would derive the best effect from our food. The tendency of the modern cook to make superfluity of garnishing conceal both merit and defect in material is to be deplored. Simplicity in design, harmonious blending of color and material, enhancing rather than disguising the individuality of each dish, with the least expenditure of money and labor, are most to be desired, and make of this indeed a fine art.

> To take some meat that some one else has bought
> And then to dress it tolerably, is
> What any cook can do.
> A perfect cook is quite another thing,
> For there are many admirable arts,
> And of all of these he must be thorough master,
> Who would excel in this. He first must have
> A smattering of painting and indeed
> Many the sciences which he must learn
> Before he's fit to think of cookery.— *Nichomachus.*

Cookery as a Science.— But little thought was given to this aspect of cookery by the ancients; probably more among the Greeks than among other nations, for the Greeks worshipped Hygeia, the goddess of health, and lived on coarse foods, barley bread, oil and

wine. Wheat was called the «marrow of man» and «running, fatigue, hunger and thirst» were their seasonings. Cookery attained a high degree of development during the Attic Age. The following quotations show that the Greeks understood the qualifications of a cook, and the effect of heat and water on food; and the third hints that our kitchen maids of to-day were not the first cooks who hurried up the fire with oil.

His mind must comprehend all facts and circumstances;
Where is the place and what the time for supper;
Who are the guests and who the entertainer;
What fish to buy and where to buy it.—*Athenæus.*

Fish that are fat are pleasant to the palate, but heavy and difficult of digestion, therefore they are better cured or roasted, for by that process their fatty parts are got rid of. Oysters when boiled get rid of most of their saltness which they infuse into the water which boils them, and this water is apt to disorder the stomach; but roasted oysters have all their evil properties removed by the fire.—*Mnesithus.*

Placing all my pans upon the fire, I soaked the ashes well with oil, to raise a rapid heat.—*Archedius.*

The cook held the life and honor of his master in his hands, so common was poisoning by food; honors and wealth were bestowed upon those who had ability, those from Sicily ranking highest.

It was not until chemistry had advanced to the position of an exact science, and had evolved methods of analysis for organic substances, that the nature of food constituents, the changes in the nutritive value of food brought about by cooking, and what becomes of food in the body, could be determined.

Although vast strides have been made since Count Rumford, an American, who lived in Europe the latter part of the 18th century, taught the world how to cook and was the first to note the changes in the nutritive value of food on a large scale, the insight and method of the scientist,—the science of cookery is yet in its infancy.

The Agricultural Department in Washington has done a fine work along the lines of scientific analysis and experiment in food values, and its bulletins, issued frequently and free to any one on application, supply the latest and most reliable information. Investigations have also been made by many of the most civilized nations into the best way of preparing food for the army and the inmates of prisons and hospitals. Chefs gain their knowledge of the art of cookery by apprenticeship to noted chefs, taking a long and thorough training in every branch of the work. Training in the home, by «mother's way,» is all the teaching many skilful housekeepers have received, but this, combined with judgment and faculty, has produced much good work.

During the last half of the 19th century, schools for instruction in cookery were opened in England, the agricultural colleges of the West, New York, Boston and other large cities. Here not only the art, but the scientific principles were taught, and the pupils included children from the mission schools, servants, housekeepers, young and old, college and medical students and ladies of wealth and leisure. The first outgrowth of this beginning was the establishment of schools for training of teachers of cookery, and later cooking was made a part of the regular course in the public schools. Boston led in this part of the work, and now at the third decade of the 20th century, there are but few States in the Union and but few European countries where cooking schools are not found in successful operation.

Literature.—Cooking and feasting have been the theme of brush and pen, of song and romance in all countries, and from the earliest days of book-making, cookery has had quite a literature of its own. The names of Archestratus, Herodotus, Homer, Apicius, Lucullus and many others are associated in the minds of the student with the cookery and banquets of the Greeks and Romans. To attempt to enumerate those who have helped in the development of modern Italian, French and English cookery would be to do injustice to many of whom limited space would prevent mention. If one were to ask for the catalogue of culinary literature in any large public library in America, it would be found to be quite a volume, so rapidly has the literature of cookery multiplied, since it has taken front rank among the arts and sciences.

It has been claimed that men are the only really good cooks, chiefly because they make it their business for life and strive to excel in the art, whereas women adopt it only as a means of support until marriage relieves them from its necessity. And Dr. Johnson said that «women could not write good cook books.» Perhaps men are better fitted to be chefs in hotels and large establishments, and to work with and manage a great body of men, and from having no other duties they have had ample time and means to give the subject more study. But when we recall the many women who have always prepared good, wholesome (if not fancy) food for their large families,—those who have catered to institutions, and those who have done fine work in teaching the science of cookery in schools and by their books and lectures, we question the statement. The American cook book of the 20th century is not a mere compilation of untried and inaccurate recipes, it is not a record of only one person's experience, where much is left to judgment, nor of a style of living too extravagant for the average home; but it is an evolution from the best experience of all nations, a collection of exact formulæ deduced from actual experiment, giving the results of the latest scientific research, and all presented in an entertaining way in the best literary style.

Evolution.—The evolution of cookery, as traced in food, would be something after this order: The first foods were natural; milk, wild fruits, and vegetables, flesh and fish, eggs and animal fats, honey and salt, oily seeds and beverages made from simple fermentation of fruit-juices and of milk. The second stage might be called one of cultivated and manufactured or combined foods: the cereals, grains and legumes were developed into bread, cakes, puddings and malted drinks, milk into butter and cheese; intercourse with other nations brought a great variety of vegetables, fruits, condiments and beverages. The present stage is one of refined foods. The refinement of flour and yeast, the concentration of the sapid principle in meat and its use in soups and sauces, the refinement of fruit and vegetable juices into sugar, and its increased use in fancy cakes, pastry, desserts and artistic confectionery, are typical of the most advanced and refined forms of cookery.

In tracing the evolution of cookery among different nations, we find it has had the customary rise and fall of all the arts; increasing in variety, magnitude and indulgence with the growth and prosperity of each nation; its national characteristics always largely determined by climate and natural advantages, but varied by invasion, intermarriage of rulers and nobility, and the advance of civilization. Persia with her fruits, sweets, wines and her lavish display modified the simplicity of the Greeks; the luxury and extravagance of the Romans disappeared under the invasion of the Goths, who cared only for wild fruits, fowl, venison, horseflesh and curdled milk. During the Middle Ages the best cooking was done in the monasteries. They had ample means and their many fast days incited them to the invention of many disguises. In Italy during the Renaissance, cookery, with the other arts, became more refined, and France soon felt the influence, through the Medici. She had early learned economy through necessity from famine and the exactions of her rulers; her many revolutions compelled every peasant to learn to make something savory of weeds, acorns, snails, rats and other things which many nations reject. Modern French cookery dates from Louis XIV and attained great height under his successors. The nobility and even royalty spent much time concocting new dishes; Richelieu made mayonnaise, and Bechamel the sauce bearing his name. The French made great use of meat essence as a dressing for meats, and it was considered a great improvement over the oil of the south and the animal fats of the north. Large amounts of meat, poultry and game were often used solely to secure a small amount of glaze with which to dress an entrée; this shows an extravagant as well as an economical side to French cookery. Under Napoleon French influence was widely extended and it is said he left a French chef in every land he invaded. There are more chefs from France in America than from any other country. Austria and Switzerland rank next to France in excellence of home cookery. England's love for pork began with the Saxon invasion, and though condemned by some of her colonists, it is yet the mainstay of her laboring classes. The coarse tastes of the Danes were modified by the soups and stews of the Normans. Many of our culinary terms are of Norman origin, and the surnames Cook and Butler came from professionals in that time. After groaning for centuries under saddles and sirloins, England's tables became more simple, for after the Reformation rich cooking was considered popish. Although modified by the modern French, England is still the great meat-eating nation. "The English do their culinary work at the table with their palate-scorching table sauces, but the French do theirs in their saucepans." Scotland with her barren hills lacked vegetables, but mutton, game and fish were abundant; her cock-a-leekie and haggis show the influence of France.

There are still a few distinctly American dishes, many of them borrowed from the Indians, some made from native products, but a large number are but modifications of the customs in the homes of the earliest settlers. The Yankee's love for pie may be traced to the mother country, and for the doughnut to Holland. The Dutch left a strong impress on New York and the Germans in the middle States. Extravagance in methods, great waste of fuel and material and the indigestibility of some of our national dishes have been our defects, but a large part of genuine American cookery will compare favorably with that of other nations. Within the last half century travel and wealth have changed our tastes in a measure, enabling many to have chefs from abroad who command very high salaries. We have gained much of value from China and Japan. France has done more than any other nation in teaching us economy and artistic effect, and the influence of Spain is apparent on our western coast and our new possessions. The advantage of this influx of foreign elements into our cuisine has been greatest in cities and among traveled classes. In remote country places and everywhere among native laboring communities, there is need of knowledge of some of the economical foreign methods. Cooking teachers find it wise to accept some of the suggestions from their pupils of German and Italian parentage, instead of insisting that our methods are always the best. No doubt many foreign nations would derive equal benefit and enjoyment from some of our dishes which are seldom seen there. Canvasback ducks, softshell crabs, strawberry shortcake, fish balls, pumpkin pie, prairie chicken, red-snapper, cranberries and oyster in many ways are eagerly welcomed by the returning traveler.

The cultivated American of colonial descent, while loyal to the virtues of succotash and the four B's of Boston, which are similar in nature and food value to the tortilla and frijoles of Mexico and the lentils of Egypt, is learning what to accept and what to reject from the solid puddings, pastry, bread and meats of England; the spicy cakes, sour vegetables, sausages and delicatessen supplies of Germany; the complex soups, sauces, entrées, soufflés and artistic disguises of the French; the pungent Spanish puchera; the savory Hungarian goulash and Turkish pilaf; the Italian palenta, risotto and macaroni; the hors d'œuvres of Russia and Scandinavia, and the curries and fruits of the tropics; and from them all he is beginning to evolve a simplicity and an individuality which may be characterized as truly American. He prefers on his meat the sauce of its own juices; he insists on having no doubt as to the identity of his veal and chicken; he has accepted the piquancy of the green salad with its soothing oil in place of the sweets of the pudding and the sharpness of his mother's pickles. The nutty Vienna roll has taken the place of the half-baked raised biscuit, and he finds the bit of cheese which is the main food of the Swiss or Holland peasant, with the fruits and nuts of the savage, a good substitute for the soggy pie of his aristocratic ancestor.

Evolution of Methods of Cookery.— It is sufficient for our purpose here to consider foods merely as animal and vegetable, with albumen as the type of the former, and starch of the latter, albumen requiring a low and starch a high temperature. (See Food). Starch and albumen are frequently combined in natural food, and still more frequently in cooked food, but they must be digested by fluids of a different nature, one an alkaline and the other an acid. Therefore, how to cook them that each

may best do its work in the body is the problem of good cookery.

Heat.— Cooking means, to prepare by heat (Latin *coquo*), and in all its phases heat is the important factor. The heat of the sun causes plant food to grow and ripen; the heat of the living animal prepares its flesh and products for the higher animal, man; he applies artificial heat in cooking vegetable and animal foods, and after eating them, his own internal heat helps in the assimilation of the food into his body. The absence of heat sufficient to be called *cold* is essential to make many foods more palatable. Water is removed from some foods by concentration, and added to others for the solution of albumen and the hydration of starch. Air, for the expansion of various substances the development of improved flavors and the dissipation of disagreeable odors is essential, and care should be taken that it be pure as possible.

Fuel.— Heat for cooking purposes was obtained first by drying foods in the sun. Many kinds of flesh, fish and fruit are still prepared in this way. Then came the burning of wood, oil, coal, gas, coal oil and alcohol; the latest advance is the use of electricity, the expense of which has retarded its adoption, but its merits are great and its possibilities unlimited.

Heat is applied to food in two ways: through hot air, as in broiling, roasting and baking; and through hot liquids, as in boiling, frying and their variations.

Broiling or *Grilling* is cooking by close contact with the fire. The primitive way was on the coals: the smoke and ashes may have led the barbarian to wind the meat round a stick and hold it over the fire, much as the Turks do now with their strips of mutton or kabobs. To save personal attention the meat was suspended from a stick; later it was cooked on bars of wood or iron, called a gridiron, hence our word grilling, and was turned when partly cooked. The modern improvement of this time-honored method is the wire broiler, used over red-hot charcoal, or under the gas flame, and frequent turning has been found to be the secret of good broiling. Contact with the fire sears the fibres, with a slight loss of outside substance, but it seals the juices inside and gives the richest possible flavor. "The gridiron is the thermometer of civilization." *Toasting* is simply the broiling of bread and other cooked starchy foods, in order to develop dextrin. It sometimes develops charcoal. *Pan-broiling* is cooking in a very hot dry pan, with sometimes the merest film of grease to prevent too great loss of substance by adhesion. The quick searing gives almost the same flavor as in direct broiling. It is a convenient way for the chafing dish and oil stove.

> Put the anchovies in the heated pan and in a moment
> They will begin to hiss and are done.— *Archestratus.*

Roasting is a modification of broiling, at a lower temperature, adapted to large pieces of meat and poultry, which, on account of their thickness, are placed at a greater distance from the fire after the first searing. In early times the animal was dressed and hung at once over the fire; when the fire was made in a hole, sticks were laid across on which the animal rested; we call it a barbecue. After fires were built on the hearthstones and cooking was done inside, the meat was hung on a frame placed in front of the fire, and was turned and basted by the cook's attendants. This was the common way of cooking meat in the great baronial halls of England for many centuries and may still be seen in old country inns. The modern spit has its clock-work attachments, which turn the meat, dip up the gravy and pour it over at regular intervals. In warm countries but little roasting is done; and although once the only way in America, it is now seldom used except in hotels, and by those who have ranges with a special attachment for roasting, or who have revived the old custom on the hearth of their country kitchens; for there are many who still think the old Greek method greatly superior to the cooking of meat in the oven, which is commonly called roasting.

> Many are the ways and many the recipes
> For dressing a hare, but this is best of all.
> To place before a set of hungry guests
> A slice of roasted meat fresh from the spit,
> Hot, seasoned only with plain simple salt,
> Not too much done. And do not you be vexed
> At seeing blood fresh trickling from the meat,
> But eat it eagerly. All other ways
> Are quite superfluous, such as when cooks pour
> A lot of sticky, clammy sauce upon it.— *Archestratus.*

Baking is cooking by the heat radiating from a hot oven. The principle is the same as in roasting and broiling, namely, a quick searing of the outer surface for the sake of the flavor and to retain the juices, then a lower temperature that the heat may reach the centre without burning the outside. If the oven is not hot, or water is used at first, the juices are drawn into the pan, enriching the gravy at the expense of the meat. Flesh which has tough connective tissue, cartilage and bone should be cooked a long time, and needs the solvent action of water, after the first browning. Baking renders watery vegetables drier and more savory, develops new flavors in fruits and grains and changes some of the sugar in the crust of cake into caramel and the starch in the outside of bread into dextrin. Some forms of baking are so nearly allied to stewing that it is impossible to make a strict division; but there is a great difference in the flavor developed by the two methods. In baking, the temperature is the important point, varying from 212° to 400° for different articles. The oven thermometer is the evolution of the old-time "hand and try cake" methods. Baking was done first in the hot ashes, then in a hole in the ground — the primitive oven — where a fire was built on stones and after it had burned down to coals, food was laid in, either in clay pots, or wrapped in moist leaves, then covered with brush or leaves, and left to cook slowly for a long time. Bread-fruit in the South Sea Islands is baked in this way. Pounded and moistened grains made into a thin batter were spread on hot stones by a dextrous sweep of the hand, cooking almost instantly; this was the first bread; the process may be seen now among the Arizona Indians in making piki. Some one found it better to cover the oven permanently and have an opening at one end; this was the beginning of the brick oven.

At the hearth fires, a covered utensil to stand near or over the coals, and later the Dutch oven, answered for daily use; the great brick oven near the chimney soon followed, and here enough "rye and injun" bread, pies,

cookies, Indian meal pudding, and beans, were baked to last a large family through the week.

The kitchen range is an evolution of an American invention about the beginning of the 19th century. In many European countries they still use tile and brick stoves without ovens, all of the baking being done outside the home. In America there are ovens of every size and kind, from the tiny tin box for the gas burner or oil stove, the jacketed box of the Aladdin oven, which concentrates and utilizes all the heat from an oil lamp, the ventilated ovens of the coal and gas ranges, to the immense ovens of the large baking establishments, with their steam jets, revolving shelves and griddles and other contrivances for securing the right temperature and texture.

Frying is immersion in hot fat: from 345° to 400°. This is not boiling fat, as it is often called; it is the water in the food, or the fat, if new, which bubbles. Immersion implies depth enough to cover the articles, that the surface may be hardened before the fat can penetrate the food. A coating of egg and crumbs helps a moist surface to harden quickly and keep its shape. Some previously cooked foods are fried merely for the flavor and crispness of the crust. Frying has been called the "curse of American cookery," but it is the wrong use of it that merits condemnation. Tough meat and flour mixtures rank with soda, put into cold lard and left to stew and sizzle until hard and soaked with burned grease, have been all too frequently a large part of the daily food on many American tables. It may have originated when it was so much an undertaking to "fire up" the brick oven, and the drafts prevented the food in the Dutch oven from getting beyond the palest tint of brown. But there are indications that the boiler, the Scotch bowl, and the stew pan, are taking the place of the spider. When at its best frying is not to be recommended for those with weak digestion, its only merit being its quickness, but this is gained at the expense of time in the last stage of the work, digestion. But little frying would be done if everyone had to fry his food and inhale the odors. Frying probably originated where olive-oil was in common use, and oil is still the general frying medium in countries bordering on the Mediterranean. There it is usually done well, for vegetable oil may be heated with less acrid odor than from animal fats. When a pure vegetable oil without odor can be procured at reasonable rates in America, and when housekeepers are willing to believe that it is more economical to fry in a large amount of fat at high temperature and drain the fried food thoroughly, than to let a smaller amount of fat be absorbed by the food, frying will be greatly improved. *Sautéing* is a French term meaning "to toss," or turn over. It is the common way to cook omelets, mushrooms and other foods which need merely to be browned on each side in a little fat, or stewed in hot butter and tossed about until cooked. *Griddle Baking,* sometimes called frying, is cooking on a hot griddle, with no fat, if of soapstone, and but little if of iron. The griddle is shallow and would not hold fat. For waffles and fancy wafers the griddle is double and revolves over the fire.

Boiling and *Simmering,* terms often applied to cooking in water, regardless of temperature, so long as it is on the fire. At the sea-level, water *simmers,* or bubbles gently below the surface at 185°, and *boils,* or bubbles all over the surface, at 212°. Density, weather and altitude vary the boiling temperature more or less, but it is easier to make some cooks understand this, than to convince them that water cannot be made any hotter after it once boils all over, at least not in the ordinary kettle. The scientifically trained cook knows that "just a smile at one side of the meat" will cook it perfectly, and some of the foreign peasants seem to have known it intuitively, but the average cook in our kitchens piles on the coal until the water "dances a jig," and then wonders that her meat is stringy and tasteless. The first knows that if she wishes good broth or stock, she must cut the meat small, put it into cold water and let the juices soak out, then heat this water to the simmering point. But the average cook never can remember when to use hot, when to use boiling and when to use cold water. The educated cook knows that rapid boiling is advisable for the first 5 or 10 minutes, to seal the juices inside in boiled meat,—the thinner the meat the shorter the time—and also to cook the starch in grains and vegetables; and that after this, the water should only simmer else there will be great washing out of substance. She knows, too, that when particles of food are to be kept in motion, to prevent adhesion among themselves or to the kettle, as in cooking rice and macaroni, the rapid boiling may be continued that "the rice may dance about." But to the average mind the cooking of food in water is probably more or less guesswork, judging by the results.

Stewing is only another form of simmering. In making a soup a large amount of water is used, and in making a stew a small amount. In both, the cooking is continued a long time at a gentle heat. Tough meats are improved in flavor by the union with vegetables, spices and other seasonings. In the soup they are removed, if it is to be clear, but in the stew they are retained. When dumplings of biscuit dough are cooked as a cover for the stew, or shortcake is served around the stew, it becomes a pot pie.

Fricasseeing, meaning "to fry," is a combination of frying with stewing, by which a flavor like that in frying, or pan broiling, is obtained.

The term is sometimes used when no real browning is done, the simple warming, or stewing in butter at a low temperature, making it, according to some authorities, a fricassee. It is to be regretted that the desire for new names (thinking thereby to have a new dish) has almost obliterated the true meaning of many culinary terms; there seems to be no standard for nomenclature.

Braising is a combination of frying, stewing and baking, with vegetables, etc., formerly done in a stew-pan having a hollow cover, in which coals were put for the final browning. It is a common way in foreign lands, where ovens are not much used and fuel scanty, only a little being needed for the slow fire for stewing, and each half-burned bit carefully put out by water and laid aside for another time. Braising is now done in an earthen dish called a casserole, and foods à la casserole are becoming very popular at hotels. It may be done in a granite pan with a tight cover and finished

in the oven. It is one of the most savory ways of cooking meat, game and poultry.

Smothering, or *Pot-roasting,* is done by quick searing of meat in a little of its own fat, in the stew pan or pot, then adding barely enough water to prevent burning, covering closely (formerly with a lid of dough when it was done in an iron pot before the fire), and cooking slowly in the steam of its own juices. It gives rich, undiluted gravy and very tender fibre; the best way to cook tough lean meat free from bone.

Steaming.— Real steaming is done chiefly in factories, or large establishments, where the steam is confined in boilers and superheated, and then conveyed through pipes to the kettle containing the food. Owing to the expansive force of steam it cannot be confined in an ordinary kettle, and many of our canned fruits, soups and vegetables are more successfully done there, than they could be at home. But we cook some foods over, or surrounded by boiling water, and call it steaming. In the first way, the food is placed on a perforated pan, above the water, the moist steam surrounds it, and in condensing gives up its heat, which cooks the food. In the second way, a double or farina boiler is used (or a pail inside a common kettle), the heat is conveyed by the steam or boiling water through the metal, and thence to the food, which is less hot than the water, as the metal has absorbed some of the heat. Steaming makes tough meat tender and moist, and enables us to cook vegetables and glutinous foods without the constant attention needed, if cooked over the fire, or in a little water. The Romans had a kind of double boiler, also the chafing dish, which is one variety, combined with a sautéing pan. Our grandmothers could cook a pot of hasty pudding without burning it; but with the advent of many more glutinous foods and the knowledge that many foods containing milk and eggs need a low temperature, a great variety of steamers and double boilers have come into use. Our grandmothers lived in their kitchens; it was but little work to "watch the pot" while they spun or wove, and the great kettle of cider apple sauce seldom had even a hint of scorching. But the modern housewife aims to spend as little time as possible in her kitchen. When we learn to think of it as a laboratory, it may tempt (although it may not require) a longer sojourn.

Cooking in water was probably the last to be discovered of the primitive methods, for it could not have been done until water-tight utensils were made; there were, first, baskets, made by plaiting grasses, twigs and rushes; then bowls or troughs were made by burning out hollow places in a log. Stones were heated in the fire and plunged into the water in these baskets or troughs, and this cooked the food. Indians cook their acorn mush in this way, and the Alaskans use their canoes for boilers, heating the water with hot stones, when they boil the salmon for its oil. When clay was found, they learned to shape it into bowls, then into pots with three legs, and thus had a fire-proof as well as water-tight utensil; and after this stewing came into general use. Jacob's savory venison was probably stewed. In spite of luxury, the old men in Greece preferred the black broth made of cuttle-fish. "Rome was raised on gruel," or pulse, made of barley and vegetables, and it is probable that stewing in some of its forms has been the method in most general use, among the masses of the people, who from limitation of means and of food supplies have learned its value. Stewing is not advisable, as commonly done in America, where a large amount of fire must be kept in one of our immense ranges especially for this purpose, but when it can be done over just the small amount of fire or gas needed, it is undoubtedly the most economical and nutritious way of cooking the cheaper kinds of meat, fish and poultry, and it is capable of many variations. But the average American man of moderate means does not take kindly to cheap meat. In this "land of the free and equal," he aims to have as nice a cut of steak as his rich employer, and his helpless helpmate probably knows no other way to cook meat save in the omnipresent frying-pan, and has no idea of the principles of the Norwegian cooker. Americans, with the best vegetables in the world, have much to learn about the cooking of them. Too much water and too little cooking are the American faults; just enough butter or oil to prevent burning, and then a slow stewing in their own juices,— saving them generally, instead of throwing them out in the water,— is the better way for many vegetables. Our beverages, our soups, our steamed puddings, our candy and many other foods, are palatable or otherwise, according to our knowledge of cooking in water. A question asked by a lady in the early days of cooking-schools shows the lamentable ignorance of many women on this important subject: "How shall I know when the water boils?"

It is interesting to note that every primitive method has its counterpart now, not only among the barbarous people, but we find that persons of the highest civilization and refinement adopt some of them instinctively, when camping necessities suggest their use, or the satiated appetite craves simplicity. No foreign chef has produced anything finer than the trout cooked on a swinging birch bough before the camp door, a potato baked in hot ashes, scalded corn-meal baked on a board on the hearth, sweet corn roasted on hot stones, a planked shad, a Louisiana gumbo, a Brunswick stew, a Rhode Island clam-bake, or beans and pork baked in a bean-hole in the Maine woods.

Revolution.— Many thoughtful minds prophesy that the next step in the evolution of cookery will be one of "revolution among the eaters themselves." Already many have revolted against meat and other animal foods, vegetarianism having made great advance in favor. Much of the laborious part of cooking has been taken from the home to the public kitchens and bakeries, or to the manufactory of prepared foods ready for the table. The overtaxed digestive organs are demanding relief, by a change to more simple living. A few persons are beginning to understand that the man of moderate means spends too large a portion of his earnings for his food; that there is great waste of labor, fuel, heat, comfort, temper, health and morality in the cooking of food; that intemperance in eating produces as direful results as intemperance in drinking; that "a man is what he eats," and that high thinking comes easiest after plain living.

Special directions for preparing and cooking fruits and nuts, making breads, cake, pastries, etc., can be found in the many books and journals devoted to cookery. Every precaution should be taken to ensure cleanliness in the cooking of food. In the United States and in other countries there is a growing effort to secure cleanliness in markets, food factories, bakeries, hotels, restaurants and other places where food is handled, prepared, sold and eaten. With this end in view legislation has been enacted in many places, providing for inspection and for punishment if the law is violated.

Bibliography.—Farmer, F. M., 'Boston Cooking-school Cook Book' (Boston 1936); Rector, G., 'Dine at Home with Rector' (New York 1937); Lord, I. E., ed. COOKEVILLE, Tenn., seat of Putnam County, alt. 1,050 feet, 75 miles east of Nashville; on the Tennessee Central Railway. Here are the State Polytechnic Institute and lumber and pottery factories. It has a commission government. Pop. (1940) 4,364.

COOKS PEAK. The highest summit of Cooks range in the northern part of Luna County, New Mexico, 25 miles north, slightly east of Deming. A prominent landmark to travellers on the old Butterfield emigrant trail which crosses the range not far south. Consists of porphyry intruded in Palæozoic and Mesozoic rocks. Important mining district on its east and north slopes. Altitude 8,408½ feet.

COOK'S VOYAGES. See COOK, JAMES.

COOKTOWN, Australia, town and port of Banks County, Queensland, at the mouth of the Endeavor River, 1,050 miles northwest of Brisbane, with which and with other ports it is connected by steamship service. It is connected by rail with Laura in the gold fields, 67 miles westward. It was here that Captain Cook beached the *Endeavor* in 1770 after he had gotten her off a reef outside, having thrown his guns overboard to keep the ship afloat. Search has failed to recover the guns, which have evidently been covered up by the strong coral growths of the vicinity. A monument to Captain Cook was unveiled in 1889. There are fine public buildings, an admirable hospital, churches, schools, etc. It is the main port for trade with New Guinea, and is the outlet for a sugar country and a rich mineral country. It has pearl fisheries, coffee and rice are grown nearby, tin and gold mined. Pop. 881.

COOKWORTHY, William, English apothecary and ceramist: b. Kingsbridge, Devonshire, 1705; d. 1780. An apothecary by profession, Cookworthy became famous through his discovery about 1758 of the kaolin deposits in Cornwall and Devon, upon which English hard porcelain and fine earthenware makers still depend. The successful culmination of his work followed years of patient surveys. See CERAMICS; KAOLIN.

COOLBRITH, Ina Donna, American poet; b. near Springfield, Ill., 10 March 1842; d. Berkeley, Calif., 29 Feb. 1928. She was associated with Bret Harte in editing the *Overland Monthly;* contributed verse to leading magazines; and in 1915, by an act of the state legislature, she became poet laureate of California. She published 'A Perfect Day and Other Poems' (1881); 'The Singer of the Sea' (1894); and 'Songs from the Golden Gate', her collected works (1895.)

COOLEY, Leroy Clark, American physicist: b. Point Peninsula, N. Y., 7 Oct. 1833; d. Poughkeepsie, N. Y., 21 Sept. 1916. He was graduated at Union College 1858, taught physical science in New York State Normal College 1860–74, when he became professor of physics in Vassar College, remaining in this relation until 1907. He wrote several elementary textbooks on natural philosophy, chemistry, etc., the most recent being 'Beginner's Guide to Chemistry' (1886); 'Laboratory Studies in Chemistry' (1894); 'Student's Manual of Physics' (1897).

COOLEY, Mortimer Elwyn, American engineer: b. Canandaigua, N. Y., 28 March 1855. He was graduated from the United States Naval Academy in 1878; in 1881 became professor of mechanical engineering and in 1904 dean of the department of engineering at the University of Michigan; was chief engineer in the United States Navy during the Spanish-American War, and chief engineer officer of the Michigan Naval Brigade from 1895 to 1911. After 1900 he was known as an expert investigator and appraiser of public utilities through his work in appraising the railroads and public-service corporations of Michigan in 1900–01, 1903–05, and 1910–11, and through his municipal investigations in New York, Chicago, Boston and other cities. From 1907 to 1912 he was chairman of the Block Signal and Train Control Board of the Interstate Commerce Commission. He was a member of the American Society of Mechanical Engineers and many other learned bodies. D. 25 Aug. 1944.

COOLEY, Thomas McIntyre, American jurist: b. Attica, N. Y., 6 Jan. 1824; d. Ann Arbor, Mich., 12 Sept. 1898. He was admitted to the bar in 1846 and became professor of law in the University of Michigan in 1859. He was elected justice of the Supreme Court of Michigan in 1864 and was chief justice of that State 1868–69, retiring from the bench in 1885. In 1881 he again became professor of law in the University of Michigan. His principal works are 'A Treatise Upon Wrongs and Their Remedies' (1878); 'General Principles of Constitutional Law in the United States' (1880); 'Commentaries on the Constitution of the United States' (1873); 'Law of Taxation' (1876); 'Michigan' in 'American Commonwealth Series.'

COOLIDGE, Archibald Cary, American educator: b. Boston, Mass., 6 March 1866; d. there, 14 Jan. 1928. He was educated at Harvard, Berlin, the École des Sciences Politiques, Paris, and the University of Freiburg. He was acting secretary to the American legation at Saint Petersburg in 1890–91 and secretary to the American legation at Vienna in 1893. In 1893–99 he was instructor in history at Harvard, from 1899 to 1908 assistant professor and thereafter professor; in 1911 he also became

director of the university library. He was a member of the Taft party to the Philippine Islands in 1905–06, Harvard lecturer at various French universities in 1906–07 and delegate to the Pan-American Scientific Congress at Santiago, Chile, in 1908–09. In 1913–14 he was American exchange professor at the University of Berlin. He is the author of *The United States as a World Power* (1908; French and German translations); *The Origins of the Triple Alliance* (1917).

COOLIDGE, Calvin, 29th president of the United States: b. Plymouth, Vt., July 4, 1872; d. Northampton, Mass., Jan. 6, 1933. Graduated from Amherst College, 1895; studied law with Hammond and Field at Northampton, and began practice at Northampton in 1897. His public career began two years later with his election to the city council. He was city solicitor, 1900–01; clerk of courts, 1904; member, Massachusetts House of Representatives, 1907–08; mayor, Northampton, 1910–11; member, state Senate, 1912–15 (president, 1914–15); lieutenant governor, 1916–18; elected governor, 1918; re-elected, 1919, by the unprecedented plurality of 124,000 votes. In September 1919 Governor Coolidge was brought into national prominence by his determined stand against the unionization and strike of the Boston police. His message to President Samuel Gompers of the American Federation of Labor, asserting "there is no right to strike against the public safety by anybody, anywhere, anytime," was so universally applauded as a manifestation of moral courage that his friends began immediately to urge his nomination for the presidency. His name was placed before the Republican National Convention held at Chicago, June 1920, and he received 34 votes. When the nomination went to Senator Warren G. Harding of Ohio, Governor Coolidge was nominated for vice president, receiving 674½ votes on the first ballot. He was elected Nov. 2 and took office March 4, 1921. Mr. Coolidge succeeded to the presidency upon the death, Aug. 2, 1923, of President Harding. The oath of office was administered by his father, John C. Coolidge, a justice of the peace, at the latter's home at Plymouth, Vt. at 2:30 A.M., August 3. In 1924 Mr. Coolidge was nominated by his party to succeed himself and at the election in November received a popular vote of 15,718,789 as compared with 8,378,962 votes cast for John W. Davis, his Democratic opponent, and 4,822,319 votes cast for the late Senator Robert M. La Follette, Sr., who ran as a Progressive. The vote in the Electoral College was: Coolidge, 382; Davis, 136; La Follette, 13. Mr. Coolidge was an ardent advocate of economy in governmental expenditures. His administration materially reduced income taxes, and in the first three years of its existence reduced the national debt over $2,000,000,000. Under him the war debts with foreign countries were adjusted. He appointed the commission that drafted the Dawes Plan for the payment of German reparations. To the prevailing impression that he was "safe and sane" is attributed an era of unusual industrial prosperity that began shortly after his election and continued beyond his presidency. On Oct. 4, 1905 Mr. Coolidge married Miss Grace A. Goodhue of Burlington, Vt. Consult, White, William Allen, *A Puritan in Babylon* (1938).

COOLIDGE, Charles Allerton, American architect: b. Boston, Mass., Nov. 30, 1858; A.B. Harvard, 1881. Among the notable buildings planned by him are those of Stanford University, the Chicago Public Library and Art Institute, and Rockefeller Institute. Died April 1, 1936.

COOLIDGE, Susan. See WOOLSEY, SARAH C.

COOLIDGE DAM, Ariz., town of Pinal County at the Coolidge Dam on the Gila River 90 miles east of Phoenix. Pop. 2,091.

COOLIE, a term commonly applied to unskilled laborers from India and China. The first coolie emigrants appear to have been Indians, brought from Calcutta, in India, to British Guiana, in 1839, soon after the abolition of slavery in that colony freed the Negroes. The Chinese coolie traffic was publicly recognized in 1844 when the British colony of Guiana made provision for the encouragement of Chinese immigration. For a certain specified amount, generally about 17s a month, the coolies were bound for a term of years and after 10 years' service they were entitled to free passage back to their native country. The Chinese coolies were not entitled to this back-passage. To entice the skilled laborers to remain inducements were offered them, and many did remain. The coolies employed in Guiana, chiefly from India, were in 1891 in number 105,463. The first attempt to use people from India as laborers proved unsuccessful. Various abuses existed almost from the beginning, in the treatment of the laborers. The transport ships were crowded so that few survived the passage; the survivors were often sold, and many were sent, contrary to their agreement, to work in the foul guano pits in Peru, where huge numbers perished. The Chinese Passengers' Act of 1855 put an end to the more abominable phases of the traffic. No British ship was allowed to sail on more than a week's voyage with more than 20 coolies on board, unless her master had complied with certain very stringent regulations. This ruling enabled the Portuguese to gain almost entire control of the trade. The abuses which had crept in made the trade almost as bad as the trade in African slaves. The legislature of Jamaica, in 1869, passed a law requiring more humane treatment from employers toward their coolies. Macao, the Portuguese port at the mouth of the Canton River, China, sent large numbers of Chinese coolies to Cuba and Peru and under conditions little short of absolute slavery, even kidnapping was practiced with impunity. In 1866 the matter was made subject to an international conference and improvements were made by agreements signed by China, France and Great Britain. By this agreement, the legalized coolie trade between the West Indies and China was abolished. In 1904, under a convention drawn up between China and the United Kingdom, over 50,000 Chinese laborers were engaged at work in the gold mines of Transvaal. To the Malay states and other parts of eastern Asia, there is an extensive yearly migration of Chinese coolies not under contract.

The name is also applied to the Chinese immigrants to the United States. The Chinese Exclusion Act of 1888 and the stringent laws against contract laborers have greatly limited the number of Chinese in this

country. (See CHINESE IMMIGRATION). Consult Hope, J. L. A., 'In Quest of Coolies' (1872); Jenkins, E., 'The Coolie; His Rights and His Wrongs' (1871); Grose, C. B., 'The Labour Ordinances' (Georgetown 1890) and reports of the commissions.

COOLING, Velocity of, a body isolated in air or other gas, or *in vacuo,* and surrounded by bodies colder than itself, loses heat, by radiation in the last mentioned case, and in the former case partly by radiation and partly by convection. The rate at which its temperature decreases depends on a variety of circumstances,—on the nature of its surface, for example. But, other things remaining the same, the velocity of cooling is proportional to the excess of the temperature of the body in question above that of its surroundings. This is Newton's Law of Cooling.

The law of cooling has been verified by Dulong and Petit experimentally. A copper ball was suspended in the midst of a metallic chamber, round the outside of which water was kept flowing, in order to maintain a constant temperature. The copper ball was heated before being suspended in the chamber, and a thermometer was inserted in a hole in the ball, and so arranged that the stem, which was long, projected to the outside of the chamber and could be read there. The fall of the temperature of the ball during equal intervals of time was noted, and it was found to become less and less as the temperature of the ball gradually approached that of the walls of the surrounding chamber, the law of decrease being Newton's as stated above.

The following example will illustrate practically the meaning of this law: Suppose the temperature of the ball to be 20° higher than that of the enclosure at the beginning of the experiment, and that during the first five minutes it loses 1°, that is, one-twentieth or 5 per cent of the excess of temperature. During the next five minutes it will lose 5 per cent of the excess that remains, that is, of 19°. It will therefore lose 0.95°, or the temperature of the ball will be 18.05° above that of the enclosure. At the end of the next five minutes the difference of temperatures of the ball and enclosure will be 17.15°, and so on.

COOLING SYSTEMS. See INTERNAL COMBUSTION ENGINE.

COOMASSIE, koo-mäs'sē, or **KUMASSI,** Africa, capital of Ashanti, in West Africa. The houses, formed of stakes and wattle-work filled up with clay, and thatched with palm leaves, are often furnished with arcades and ornamented with painting and carved work. Coomassie was captured in 1874 by the British, and again in 1896. In 1900 they took entire possession and it is now the seat of the British resident. It has a fort and a market-place. It was made a railroad terminal in 1903 and carries on an active trade with central Africa. Pop. 25,000.

COOPER, Anthony Ashley. See SHAFTESBURY.

COOPER, SIR **Astley Paston,** English surgeon: b. Brooke Hall, Norfolk, 23 Aug. 1768; d. London, 12 Feb. 1841. He studied medicine in Edinburgh and London and in 1792 he visited Paris, where he attended the lectures of Desault and Chopart. In 1793 he was appointed professor of anatomy at Surgeon's Hall; in 1802 he received the Copley medal of the Royal Society and in 1813 became professor of comparative anatomy to the College of Surgeons, and in 1822 one of its court of examiners. In this year appeared his great work 'On Dislocations and Fractures of the Joints.' Having performed a slight operation on George IV he was created a baronet in 1821, after which his practice largely increased. In 1827 he was elected president of the Royal College of Surgeons. His 'Lectures on the Principles and Practice of Surgery' appeared in 1824–27; his 'Anatomy and Diseases of the Breast' was published (1829–40), and 'Anatomy of the Thyroid Gland' (1832). He was the first to attempt the tying of the carotid artery and the aorta. These operations were not successful in his hands, but pointed the way for further research. Consult his 'Life and Correspondence' (2 vols., London 1843).

COOPER, Charles Alfred, English journalist: b. Hull, 16 Sept. 1829; d. 1916. From 1876 to 1905 he was editor of the Edinburgh *Scotsman.* He published 'Seeking the Sun' (1891); 'Letters on South Africa' (1895); 'An Editor's Retrospect' (1896).

COOPER, Colin Campbell, American landscape painter: b. Philadelphia, Pa., 1856. He studied at the Philadelphia Academy of the Fine Arts and the Julien and other academies of Paris. After a year as teacher in Drexel Institute, Philadelphia, he settled in New York. He was one of the first to give expression to the distinctive beauty of American cities, with their skyscrapers and manifold activities. A close observer, he reminds one, in his color and atmospheric effects, of the Impressionists. He also painted cathedrals and views of quaint German cities with feeling and charm. His best-known works are 'Broad Street, New York' (Cincinnati Museum); 'The Flatiron Building' (Dallas, Tex.); 'Quebec Cathedral' (Philadelphia Art Club); 'Procession of Bruges' (1906); Lotos Club, New York); 'View of Pittsburgh'; 'Beauvais Cathedral' (1912); 'The Avenue' (1913); 'Cathedral of Siena' (1913). He was awarded silver and gold medals at the Panama-Pacific Exposition, San Francisco, in 1915. He died, 6 Nov. 1937.

COOPER, Ellwood, American horticulturist: b. Lancaster County, Pa., 24 May 1829. For 10 years he was engaged in business in Port-au-Prince, Hayti, but went to California in 1870 and devoted himself to fruit culture. He was the first manufacturer of olive oil in the United States, inventing special machinery for the purpose. He was also the inventor of machinery for hulling and pitting almonds, and for hulling and washing English walnuts. From 1885 to 1903 he was president of the California State Board of Horticulture, and for three years was president of Santa Barbara College. He published 'Statistics of Trade with Hayti' (1868); 'Forest Culture and Eucalyptus Trees' (1876); 'Olive Culture' (1882). Deceased.

COOPER, Emma Lampert, American artist, wife of Colin Campbell Cooper: b. Nunda, N. Y.; d. 30 July 1920. Educated Wells College; studied art under Harry Thompson in Paris, Kever in Holland and Chase in New York. Her principal subjects are street scenes,

interiors and landscapes. For a time she taught painting in Rochester, N. Y. At the Chicago World's Fair (1893) she received a medal for her water color, 'The Bread Winner'; and another at the Atlanta Exposition (1895) for an oil painting, 'Behind the Dunes.' Others of her pictures are 'Mother Claudius' (1890); 'Picardy Hillside' (1897); 'High Noon, Cape Ann'; 'Old Kitchen in Gruyére, Switzerland'; 'News of the Day'; 'Canal at Lisieux.'

COOPER, Frederick Taber, American author and editor: b. New York, 27 May 1864. He was educated at Harvard and Columbia universities; was assistant in Latin at Columbia 1891–94, associate professor of Latin and Sanskrit at New York University 1895–1902, literary editor of the New York *Commercial Advertiser* 1898–1904, and editor of the *Forum* 1907–09. His writings include 'History of the Nineteenth Century in Caricature' (with A. B. Maurice, 1904); 'The Craftsmanship of Writing' (1911); 'Some American Storytellers' (1911); a translation of Montessori's 'Pedagogical Anthropology' (1913); 'Thomas Alva Edison' (1914); 'Little Gold Nugget' (1928). D. 19 May 1937.

COOPER, George Henry, American naval officer: b. Fort Diamond, N. Y., 27 July 1821; d. Brooklyn, N. Y., 17 Nov. 1891. He entered the navy in 1837, became captain in 1867, commodore in 1874 and rear-admiral in 1881. He was on sea service for more than 25 years, and on shore or other duty for more than 18. In the Florida Seminole Indian War he served in co-operation with the army; during the Mexican War he led an assault against Point Isabel, was captured at Monterey, and after being exchanged took part in the attacks on Tabasco, Alvarado and Tuxpan; during the Civil War he commanded, among other vessels, the monitor *Sangamon,* which was on picket duty inside the Charleston roads. He was commandant of the Norfolk navy yard (1867–69); of yard at Pensacola, Fla., 1874–78; and of the Brooklyn navy yard, and in command of the North Atlantic squadron from 1880 until his retirement, 27 July 1884.

COOPER, Henry Ernest, Hawaiian politician: b. New Albany, Ind., 28 Aug. 1857. He was graduated at the Boston University Law School 1878; was admitted to the Suffolk County (Mass.) bar; and settled in Honolulu 1890. During the Hawaiian revolution of January 1893, he was chairman of the Committee of Safety, and on 17 Jan. 1893 read the proclamation abrogating monarchical government in the islands. He became a member of the advisory council in the provisional government; a Circuit Court judge 1893–95; Minister of Foreign Affairs 1895–99; acting President of the republic, January to March 1898, and served as head of the departments of justice, public instruction, and interior, and as attorney-general 1899–1900. He retired in 1900 and practised law in Honolulu; d. Long Beach, Calif., 15 May 1929.

COOPER, James, American senator: b. Frederick County, Md., 8 May 1810; d. Camp Chase, Columbus, Ohio, 28 March 1863. He was graduated at Washington College, Pennsylvania, 1832, studied law and began practice at Gettysburg, Pa. He was elected to Congress 1838 and 1840; to the State legislature 1843–48; was attorney-general of Pennsylvania 1848, and elected a United States senator 1849. Subsequently he settled in his native town, and when the Civil War broke out took command of the Maryland volunteers, organized them into regiments, and on 17 May 1861 was made a brigadier-general. He was in command of Camp Chase at the time of his death.

COOPER, James Fenimore: b. Burlington, N. J., 15 Sept. 1789; d. Cooperstown, N. Y., 14 Sept. 1851. His father, Judge William Cooper, removed in the year following the novelist's birth to recently acquired tracts of land, in the wilderness of central New York, about Otsego Lake, on the shore of which he had already fixed the site of the village of Cooperstown. Here he built the mansion called Otsego Hall, which his son acquired in after years, and in which he wrote the greater number of his works. Young Cooper received instruction in the family of the Rev. Mr. Ellison, rector of Saint Peter's, Albany, and then entered Yale College at 13. He neglected his studies so persistently that he was expelled in his third year. In 1806 he went to sea in a merchantman, and served in the navy in London and at Gibraltar, receiving a midshipman's commission in January 1808. He served for a time on the *Vesuvius* and then with a construction party on Lake Ontario, where he saw a new aspect of frontier life and became familiar with the details of shipbuilding. In 1811 he resigned and married a daughter of John Peter De Lancey, who came of a conspicuous Tory family. Cooper's resignation from the navy on the eve of the War of 1812 was criticized as unpatriotic and influenced by his Tory connections. For the next nine years Cooper was engaged mainly in managing and improving his farm possessions, first near Cooperstown, then in Westchester, with no discovered or suspected bent toward literature. Chancing to read a book of fiction that aroused his dislike, he professed himself able to produce a better, and being held half jocularly to the task, wrote 'Precaution,' published in 1820. It was only an indifferent novel, but it was praised by friends, and Cooper was drawn to give himself to authorship. In 1821 'The Spy' appeared, winning immediate popularity both in England and at home. Cooper's chance of success lay, not in graces of style, which he showed small disposition to cultivate, nor in imitation, but in his large knowledge of colonial and pioneer life and of the sea. In 'The Spy' he had utilized his acquaintance with many details of the Revolutionary struggle, and with Westchester as «the neutral ground.» His next work, 'The Pioneers' (1823), concerned itself with life and folk in the wilderness about Cooperstown, where he had been brought up, and which he introduced under the name of Templeton, as the centre of the action. It was the first of the «Leatherstocking Series.» In 1824 he published 'The Pilot,' in which he first makes use of his knowledge of seafaring. Suggested by 'The Pirate' of Scott, it was written to show how much more might be made of expert nautical knowledge than Scott had been able to effect. It really created a new literature of the sea. In another year Cooper had completed 'Lionel Lincoln,' a painstaking novel of Boston and the Revolution, but never popular. This was followed (1826) by 'The Last of the Mohicans,' which became quickly famous, being translated widely into foreign tongues. Its popularity was mainly due to skilful handling of the Indian

characters, Uncas and Chingachgook, and still endures.

Beginning with 1826, Cooper spent seven years in Europe, continuing his authorship, and supplying much needed knowledge of men and things. 'The Prairie,' 'The Red Rover,' 'The Wept of Wish-ton-Wish' and 'The Water Witch' continued the series begun before he sailed. On account of distorted notions held abroad concerning the people of his country, Cooper wrote 'Notions of the Americans; Picked up by a Traveling Bachelor'; but the book failed of its purpose, edifying Americans rather than enlightening Europeans. He wrote, besides, three novels, 'The Bravo,' 'The Heidenmauer' and 'The Headsman,' dealing with continental scenes and characters, but their American bias tended to lessen his popularity. His manner of meddling with unpersonal matters got him into some trouble at this time. He determined in consequence to write no more. Coming back to America, near the close of 1833, he found the general crudeness of taste and the greed of wealth more pronounced, after his foreign stay, and he did not spare his criticism. The result was greater unpopularity at home than he had incurred abroad. His combative temper prompted his putting out the satiric novel of 'The Monikins' (1835), which had small effect. In the three years following he published 'Sketches of Switzerland' and 'Gleanings in Europe,' in which he gives his impressions of the Swiss, the French, the English and the Italians, and renews his strictures on foreign and domestic faults. The result was increased bitterness and abuse. A dispute with the people of Cooperstown, over his rights in Myrtle Grove, on Otsego Lake, made matters worse, for the press of the State took sides against him, misrepresenting his motives and spirit in the case. Relief was at length secured from this sort of persecution; Cooper pursued the chief offenders for libel, and won his suits. In 1838 he published the two novels, 'Homeward Bound' and 'Home as Found,' and in the next year 'The History of the Navy of the United States,' a work long had in contemplation, and received with fresh abuse from the press. The resulting trouble was settled, by a board of arbitration, in Cooper's favor. In 1840 he published 'Mercedes of Castile,' and the famous 'Pathfinder,' followed the next year by 'The Deerslayer,' generally considered, with the preceding novel, the best of the Leather-Stocking Tales, which include, with these, 'The Last of the Mohicans,' 'The Prairie' and 'The Pioneers.' Cooper's powers of description and portraiture were now at their best. In 1842 'The Two Admirals' and 'Wing and Wing' appeared, and in 1843 'Wyandotte' and 'Ned Myers,' the latter being the true story of a sailor comrade of earlier years. In 1844 'Afloat and Ashore' came out in two parts. Three anti-rent novels, 'Satanstoe' (1845), and 'The Chainbearer' and 'The Redskins' (1846) followed; and in the last-named year 'Lives of Distinguished American Naval Officers' appeared. 'The Crater' (1847); 'Jack Tier' and 'Oak Openings' (1848); 'The Sea Lions' (1849) and 'The Ways of the Hour' (1850), all indifferent novels, complete the list of his more considerable works. His death was at Cooperstown, where he had lived mainly since 1833. Cooper was of a social temper until opposition withdrew him from society. His judgments, except in matters of tact and policy, were generally acute and sound, and his integrity was heroic. His conceptions of the Indian character have been frequently disapproved, but were the fruit of deliberate study. In spite of the faults in style, he had splendid narrative ability and the power of creating characters which are clear and strong. Harvey Birch, Natty Bumppo, Long Tom Coffin and his Indian personalities are very noteworthy. His particular value to the literature of his country lies in the fact that he opened up the course of the novels concerning the origin and heart of America, and of novels of the prairies and the sea. Balzac and Hugo gave him enthusiastic praise. The standard biography is Lounsbury's in 'American Men of Letters' series, which also contains a full bibliography and an excellent criticism. (See DEERSLAYER, THE; LAST OF THE MOHICANS, THE; PATHFINDER, THE; PILOT, THE; SPY, THE). Consult also Clymer, 'James Fenimore Cooper' (1901); Richardson, 'American Literature' (Vol. II, New York 1887–88); Wendell, 'A Literary History of America' (ib. 1900); Brownell, 'American Prose Masters' (ib. 1909); Erskine, J., in 'Leading American Novelists' (ib. 1910); Phillips, M. E., 'James Fenimore Cooper' (ib. 1912); and essays by Mark Twain, T. W. Higginson and Brander Matthews.

L. A. SHERMAN,
Professor of Literature, University of Nebraska.

COOPER, Lane, American educator: b. New Brunswick, N. J., 14 Dec. 1875. He received his education at Rutgers College, where he was graduated in 1896, studying later at the universities of Columbia, Yale, Berlin and Leipzig, and the Collège de France. In 1902 he began his connection with Cornell University, becoming instructor in English there in that year, assistant professor in 1906 and full professor in 1915. He has published 'The Prose Poetry of Thomas De Quincey' (1902); 'Theories of Style' (1907); 'Literature for Engineers' (1909); 'Manual of American Literature' (1909); 'The Power of the Eye in Coleridge' (1910); 'Concordance to the Poems of Wordsworth' (1911); 'Function of the Leader in Scholarship' (1911); 'Aristotle on the Art of Poetry' (1913); 'Methods and Aims in the Study of Literature' (1915); 'A Concordance to Horace' (1916); (editor) 'The Greek Genius and Its Influence' (1917); 'Two Views of Education' (1922); 'Milton Concordance' (1923).

COOPER, Myles, English loyalist: b. England 1735; d. Edinburgh, Scotland, 1 May 1785. He was the second president of King's College, now Columbia University, New York. He studied at Oxford, became fellow of Queen's College in 1760, and in 1761 published a volume of miscellaneous verse of correct style, but full of artificiality and classical imitations. In 1762 he became assistant to Dr. Johnson, president of King's College, and after a year as professor of moral philosophy, Cooper, then 28, was elected president in May 1763, upon the resignation of Johnson. Upon his accession the college had a faculty of four members. Both discipline and members rose during his administration, and a medical school was added. From 1767 to 1771 Cooper was in England, and after his return to America showed himself not only a typical high-churchman and Tory, but the mas-

ter of a trenchant and sarcastic pen. He published 'The American Querist' in 1774 and in the same year wrote 'A Friendly Address to All Reasonable Americans on the Subject of Our Political Confusion,' a pamphlet answered by Alexander Hamilton, then an undergraduate at King's, and by Maj.-Gen. Charles Lee, who rivaled Cooper in virulence. His 'What Think Ye of Congress Now?' (1775) urged that Americans were not bound by the decrees of Congress, as that body had transcended the powers granted to it. In the same year he was forced to leave New York, narrowly escaping ill-treatment at the hands of a mob. His departure from America he described in a poem in the *Gentleman's Magazine* for July 1776. In England he received a parish in Berkshire after a short residence at Oxford, where he preached in 1776 a sermon entitled 'National Humiliation and Repentance Recommended, and the Causes of the Present Rebellion in America Assigned,' a violent attack on the English Whigs. During the last years of his life he was senior minister of the first Episcopal chapel in Edinburgh. John Trumbull, in 'McFingal,' speaks of "punster Cooper's reverend head," and he seems to have been a wit of rather free and convivial habits. Among the men who were educated under him were Gouverneur Morris, Robert Livingston, Alexander Hamilton and John Jay. He was the prominent classical scholar of 18th century America.

COOPER, Peter, American manufacturer, inventor and philanthropist: b. New York, 12 Feb. 1791; d. there, 4 April 1883. His early education was of the scantiest description, and in boyhood he assisted his father in making hats, at 17 learning the trade of coachmaking. He subsequently invented a cloth-shearing machine and engaged in various occupations, finally settling upon the manufacture of glue, which he carried on for half a century. About 1830 he became interested in iron manufacture and in 1845 removed his iron business from New York to Trenton, N. J., and was the first to roll wrought iron beams for fire-proof structures. In 1830 he built from his own designs the first locomotive engine ever constructed in America. He was also interested in the canal system of his native State, and, at a later date, in telegraphic communications, being president of several telegraph companies. He took an active share in the enterprise which resulted in laying the first Atlantic cable. In 1876 he was nominated for the presidency of the United States by the independent party, receiving nearly 100,000 votes at the autumn elections. In 1854 he established in New York the well-known Cooper Union (q.v.). He published 'Political and Financial Opinions with an Autobiography' (1877); 'Ideas for a Science of Good Government' (1883). Consult Carter, 'Peter Cooper' (in *Century Magazine,* New York 1883–84), and Raymond, 'Peter Cooper' (ib. 1901).

COOPER, Philip Henry, American naval officer: b. Camden, N. Y., 1844; d. 1912. He was graduated from the United States Naval Academy in 1863, served on the *Constellation* in the same year, and took part in the battle of Mobile Bay. From 1867 to 1869 he was an instructor at the Naval Academy; in 1870–71 he was connected with the Tehuantepec surveying expedition, and was superintendent of the Naval Academy from 1894 to 1898. He was commander of the *Chicago* during the Spanish-American War. He attained the grade of rear-admiral in 1902; and was commander-in-chief of the Asiatic station in 1904, in which year he retired.

COOPER, Susan Fenimore, American author: b. Scarsdale, N. Y., 1813; d. Cooperstown, N. Y., 31 Dec. 1894. She was the daughter of James Fenimore Cooper, and during the last years of her father's life was his secretary and amanuensis. She was author of 'Rural Hours' (1850); 'Fields Old and New' (1854); 'The Shield: A Narrative'; 'Mount Vernon to the Children of America' (1858); 'Rhyme and Reason of Country Life'; etc.

COOPER, Theodore, American engineer: b. Cooper's Plains, N. Y., 12 Jan. 1839; d. 24 Aug. 1919; graduated, Rensselaer Polytechnic Institute, Troy, N. Y., 1858, entered the United States navy as engineer officer 1861–72, and was assistant professor at the Naval Academy 1865–68. In 1872 he assisted Capt. James B. Eads in the construction of the Saint Louis bridge, becoming, after its completion, engineer and superintendent in charge. Later he held important positions with the Delaware Bridge Company, Keystone Bridge Company and as assistant engineer in charge of the construction of the first New York elevated railroads. He was one of the five expert engineers appointed to determine the Hudson River bridge span. Until his retirement he was consulting engineer for the New York Public Library and for the Quebec bridge. He was an authority on all matters relating to iron and steel construction. He published 'General Specifications for Iron and Steel Highway Bridges and Viaducts' (1885; 7th ed., rev., 1909) and 'American Railroad Bridges' (1889).

COOPER, Thomas, American physicist and politician: b. London, 22 Oct. 1759; d. South Carolina, 11 May 1839. He was educated at Oxford, studied law and medicine and was admitted to the bar. Entering into the political agitations of the period, he was sent by the democratic clubs of England to the affiliated clubs in France. In this latter country he took part with the Girondists, but perceiving their inevitable downfall escaped to England. Edmund Burke criticized with some severity the activities of Cooper and Watt in France, and provoked a caustic reply from the former, entitled 'A Reply to Mr. Burke's Invective against Mr. Cooper and Mr. Watt' (1792). Its circulation was prohibited by the British government. While in France he had learned the secret of making chlorine from common salt, and he now became a bleacher and calico printer in Manchester, but his business was unsuccessful. He next came to America, and uniting with the Democrats opposed with vivacity the administration of John Adams. For a violent newspaper attack on Adams in 1799, he was tried for a libel under the Sedition Act of 1800, and sentenced to six months' imprisonment and a fine of $400. The Democratic party coming into power, he transacted in 1806 the business of a land commissioner on the part of the State of Pennsylvania with such energy as to triumph over difficulties with the Connecticut claimants in Luzerne County, but being ap-

pointed to the office of judge, became obnoxious to members of his own party, and was removed in 1811. He was professor of chemistry in Carlisle (now Dickinson) College, 1811–15; professor of applied chemistry and mineralogy, University of Pennsylvania, 1816–19; and in 1820 became professor of chemistry in South Carolina College, now the University of South Carolina, of which he was president until he retired in 1834. Thereafter until his death he was engaged upon a revision of the state statutes. He was alike eminent for his versatility, and for the extent of his knowledge. He published in 1794, in London, a volume of 'Information Concerning America'; in 1800 a collection of political essays; in 1812 a translation of the 'Institutes of Justinian'; in 1819 a work on 'Medical Jurisprudence'; in 1812–14 two of the five volumes entitled the 'Emporium of Arts and Sciences'; 'A practical Treatise on Dyeing and Calico Printing' (1815); and in 1826 'Lectures on the Elements of Political Economy.'

COOPER, Thomas, English Chartist and poet: b. Leicester, 20 March 1805; d. Lincoln, 15 July 1892. While a shoemaker's apprentice he studied assiduously, and in 1827 became a schoolmaster and in 1829 a Methodist preacher. In 1841 he prominently identified himself with the Chartist movement as a leader, was editor of the *Midland County Illuminator,* and was arrested in the following year on a charge of sedition. During his subsequent imprisonment for two years in Stafford he wrote a Spenserian poem entitled 'The Purgatory of Suicides' and some stories published under the title of 'Wise Saws and Modern Instances.' He lectured much as a free-thinker in London and the provinces, but in 1855 he abandoned free-thinking and began lecturing on Christian evidences. His autobiography appeared in 1872, his 'Poetical Works' in 1878 and his 'Thoughts at Fourscore and Earlier' in 1885.

COOPER, Thomas Sidney, English landscape and cattle painter: b. Canterbury, 26 Sept. 1803; d. there, 7 Feb. 1902. He studied at the Royal Academy School, went to France in 1827, and settled for three years in Brussels, where he learned much from Verboeckhoven. In 1833 he exhibited at the Academy, and in 1867 was elected Royal Academician. He exhibited at the Royal Academy 67 years successively. Among his works are 'Mountains in Cumberland' (1841); 'Ettrick Shepherds' (1842); 'Cattle at Pasture' (1843); 'Summer Evening' (1846); 'Charge of the Household Brigade — Waterloo' (1847); 'Fordwich Meadows — Sunset' (1850); 'Snowed up' (1867); 'Milking Time in the Meadows' (1869); 'Passing Shower' (1870); 'Children of the Mist' (1872); 'Monarch of the Meadows' (1873); 'There's no Place like Home' (1874); 'God's Acre' (1875); 'Maternal Affection' (1876); 'A Cool Retreat' (1877); 'Isaac's Substitute' (1880); 'Summer Evening in the Marshes' (1880); 'On Deal Common' (1880); 'Scape Goat' (1881); 'Summer Afternoon' (1882); 'A Sedgy Brook in the Meadows' (1883); 'In the Rob Roy Country' (1883). In 1882 he presented a gallery of art to his native town, and in 1890 published an autobiography entitled 'My Life.' His work is neat and highly finished in character, but conventional and displays no sympathetic study of nature, but rather an excellent imitation.

COOPER CREEK, or **BARCOO,** called by the latter name chiefly in its upper course, the largest inland river in Australia. See AUSTRALIA.

COOPER RIVER, a river of South Carolina, which rises in the eastern part of Berkeley County, flows in a generally southerly course, and empties into Charleston Harbor. Though a short river, it is remarkably wide. With the Ashley River it forms the peninsula on which Charleston is situated. It is crossed at Charleston by Cooper River Bridge, completed in 1929. See SOUTH CAROLINA.

COOPER UNION was founded in 1859 by Peter Cooper, a citizen of New York, as the result of his lifelong desire to «provide free courses of instruction in the application of Science and Art to the practical business of life.» Cooper Union consists of the following seven divisions: Institute of Technology, Night School of Engineering, Day Art School, Night Art School, Department of Social Philosophy, Museum for the Arts of Decoration, Library and Reading Room. All instruction is free and is open to all who meet the entrance requirements irrespective of race, creed, color or place of residence. The Institute of Technology provides standard four-year courses in civil, electrical, mechanical and chemical engineering; the Night School of Engineering offers the same courses, only of six years' duration; the Day and Night Schools of Art offer a four-year course in art and its industrial applications. The Department of Social Philosophy sponsors public lectures in addition to work in extension. The Museum was an essential part of Peter Cooper's scheme of giving visual instruction to workers. Since the turn of the century it has been devoted to the decorative arts, and includes the famous J. Pierpont Morgan collection of textiles, the Winslow Homer sketches, an outstanding collection of wallpapers, and an encyclopædic Picture Reference Library of 500,000 classified clippings and photographs relating to the decorative arts. The Cooper Union library embraces a free public reading room, containing approximately 88,000 volumes, including special libraries on science, technology, social sciences, and the fine and applied arts. Departmental activity in Cooper Union has been unified, ending the isolation which has existed in the major educational divisions and bringing them into closer working relationship. With the installation of the present director in 1938 a policy of Scientific Humanism, which aims to accomplish an intellectual synthesis of the natural sciences and the humanities, was inaugurated. A new undergraduate program aims to provide the student body, recruited chiefly from the metropolitan area, with advantages comparable to those existing generally in the nation's colleges and universities. Cooper Union occupies its original site in Cooper Square, New York City. In 1912 the Hewitt Building was erected, making possible the expansion of scientific and engineering laboratories, from funds raised by public subscription as a memorial to the late Abram S. Hewitt, son-in-law of Peter Cooper, and secretary of the Cooper Union from the date of its founding to the day of his death in 1903. In 1939 the student body numbered 1,806.

EDWIN SHARP BURDELL,
Director of Cooper Union.

COOPERAGE, the art of making vessels of pieces of wood bound together by hoops. Such vessels were in use among the Romans at the period of the Christian era. The upright pieces for the sides of a barrel or cask are called staves. The swelling at the middle of the barrel, called the belly or bulge, is formed by skilfully shaping each stave broad in the middle and narrowed at the ends so as to form part of the required double conoid. A skilful cooper can work this curve so accurately that no further fitting or alterations shall be needed when the staves are put together. The staves are made to meet at their inner edges and by driving the hoops very hard, the inner part is compressed till the slight gaping outside is closed, and thus slight inaccuracies of fitting are remedied. The bulging shape of barrel and cask seems only a fashion. It has been suggested that the purpose is only to make more difficult the cooper's trade. During the last few years a strong effort has been made to introduce perfectly cylindrical casks in their place; the room saved in packing cars, etc., being the strongest argument for the new shape, which could be made by much cheaper machinery besides.

There are several branches of cooperage. The wet or tight cooper makes vessels for holding liquids. The dry cooper does inferior work, such as barrels for containing dry goods, where an inferior degree of accuracy is sufficient. The white cooper makes churns, pails, etc., which for the most part have straight sides. The best work is made of oak, which must be thoroughly dried before being put together. Other woods employed are elm, pine, gum, beech and bass in the order named. In warm countries, the drying of the sun is sufficient, and casks are therefore mounted in summer only; but in the United States, artificial drying is commonly resorted to. The hoops are hammered down from the narrow to the wide part of the cask, by means of a mallet striking a piece of wood held against the hoop. Iron hoops are sometimes put on hot, in order that their contraction on cooling may bind the work together. Most ingeniously constructed machinery is now generally used in barrel-making. Like most other processes of manufacture, the cooper's trade has changed in modern times, with the substitution of machinery for hand work. Barrel-making machinery may be divided into machines for the manufacture of staves, machines for manufacturing heads and machines for setting up and finishing the barrel. Consult Wagner, 'Cooperage: A Treatise on Modern Shop-Methods and Practice' (Yonkers, N. Y., 1910); Newlin, «Tests of Wooden Barrels,» in 'Bulletin of the United States Department of Agriculture, No. 86' (1914). Statistical bulletins on tight and slack cooperage stock are compiled by the United States Census Bureau in co-operation with the Forest Service of the Department of Agriculture and are published annually. Other bulletins from the Forest Service dealing with cooperage are issued from time to time.

CO-OPERATIVE MOVEMENT, in the present accepted sense, the association of individuals to provide themselves with goods and services or to produce and dispose of the products of their labor. The advantages of co-operation are that the means of production and distribution are owned in common and the earnings of the enterprise revert to the members, not on the basis of their investment but in proportion to their personal participation in the enterprise. Co-operative associations may be divided broadly into two classes:

(1) The consumer organizations operated for the benefit of the members in their individual consumer capacity, i.e., providing goods such as food, household supplies, or providing services such as automobile repair, credit, insurance. These may be provided singly, by an association specializing in one line, or in combination, by a general-service association whose aim is to fill the needs of the members in as many lines as it is practicable to do so.

(2) The producer organizations are those operated for the benefit of the members in their producer capacity. Their function may be either (a) the marketing or processing of goods produced individually (as in the fishermen's marketing associations; the farmers' associations marketing one or more farm products; or the associations making butter, cheese, etc., from farm products received from farmer members, to be sold on the open market) or (b) the marketing of goods processed or produced collectively (as in the so-called workers' productive associations operating shingle mills, clothing factories, cigar factories, etc.).

The various forms of co-operative effort have developed unevenly in different countries, according to the aptitude of the people and the conditions and needs to be met. In countries primarily agricultural, societies for the co-operative marketing of farm products and purchase of farm supplies are of greatest numerical importance (Argentina, Denmark, Estonia, Latvia, Norway). In Bulgaria, China, India, Japan, and Rumania, the largest number of societies are of the credit type. The number of societies of specified types, in the latest year for which information is available, is shown in Table I. As the table indicates, the three most important types are the credit, consumers', and agricultural societies. The workers' productive associations are important in only a few countries, and housing associations are even scarcer.

A more accurate indication of co-operative developments is afforded by membership (Table II) than by number of associations, for in some countries the multiplicity of small associations has been a sign of weakness rather than of strength. In 1937 the membership of various types of co-operative associations totaled more than 127,000,000. This figure undoubtedly contains some duplication, as the same person may be a member of several associations of different types.

Although consumers' societies constituted only a little more than one-tenth of the total number of societies, they accounted for almost half (47.5 per cent) of the membership in 1937. Of the remaining 52.5 per cent, 15.2 per cent were in credit associations, and 20.4 per cent in agricultural organizations.

In Great Britain co-operation has succeeded best in the distributive field, that is, in co-operative stores for supplying the domestic wants of the workmen's families. In other countries, however, other phases of the movement have been more prominent. Thus, in France, agricultural associations of various types have achieved a considerable degree of success. Also, that country is one of the few in which co-operative

Table I—Number of Co-operative Associations of Specified Types, by Countries

[1]No data; [2]1931; [3]1935; [4]1934; [5]São Paulo only, 1933; [6]associations affiliated to the central union, including 11 buying clubs; [7]fishermen's only; [8]1936; [9]combined functions of consumers' and agricultural societies; [10]general purpose; [11]dairy only; [12]included in "agricultural" and "nonagricultural"; [13]cabmen's only; [14]Bombay only; [15]includes rural credit societies; [16]"nonagricultural"; includes urban credit societies; [17]includes agricultural; [18]included with credit; [19]1932; [20]1933; [21]1928; [22]1,200 in 1937.

associations have been assisted by the government, with loans and contracts. Germany is notable for the fact that the idea of co-operative credit originated there. The co-operative credit organizations of that country—the so-called People's Banks—were established through the efforts of Schulze-Delitsch about 1851. In spite of the opposition his work encountered, these credit associations spread and Germany today possesses thousands of them. Generally the members own but one share each, the price of which is high, but is paid in installments, the idea being to encourage thrift and systematic saving. These organizations put the lender's interest foremost, whereas the Raiffeisen associations—named for another German who originated them—operate primarily in the interest of the borrower. From Germany the principle of the co-operative supply of credit spread to many other countries, with some modification in form and method. Co-operative credit has been particularly effective in economically backward countries in which the people were hard pressed by debt (as in China and India).

The credit unions of the United States are a modification of the credit associations of Germany. At the end of 1938 there were 7,265 such organizations in the United States, with 1,787,858

Table II—MEMBERSHIP OF SPECIFIED TYPES OF CO-OPERATIVE SOCIETIES, BY COUNTRIES
[Data Supplied by United States Bureau of Labor Statistics]

members. They made loans in that year estimated at $172,767,000.

For some countries it is difficult to obtain reliable data regarding co-operative associations. For some countries, also, it should be pointed out that, as noted in the tables, the data relate only to associations affiliated with the central co-operative organization.

In Germany, Italy, and Japan, there has been a decrease in co-operative membership from year to year, and the societies that are left are so controlled and hampered that they can hardly be called co-operative, since they have in fact lost their autonomy and democracy. Likewise, in Austria, Czechoslovakia, and Poland, the co-operative movement presents an entirely different picture since the German invasion from that shown in the statistics for the years covered in the tables; the same is true of the movement in Spain and China, where it had been growing rapidly even during the wars. There are no recent data for the Soviet Union where, since the decree of 5 Sept. 1935, taking the urban associations, over as a state activity, only the rural societies remain co-operative, under at least the partial control of the members.

[1]New South Wales only; [2]1936; [3]affiliated to central union; [4]approximate; [5]two associations; [6]no date; [7]1934.

In six countries—Belgium, Denmark, Finland, Great Britain, Sweden, and Switzerland—the co-operative retail societies handled more than 10 per cent of the entire retail trade of the country in 1935; in Finland almost one-third (30 per cent) went through co-operative retail associations. The following statement shows the approximate percentage of total retail trade transacted by the consumers' co-operatives in various countries in 1935.

	Per cent		Per cent
Austria	5–6	Hungary	8
Belgium	10	Holland	2
Denmark	10	Sweden	11
Finland	30	Switzerland	10–12
Great Britain	10–12		

The consumers' co-operatives in the 40 countries shown in Table III had an annual aggregate business of more than four billion dollars. From the volume of trade shown it is evident that very substantial savings are made for the members. In Great Britain alone the retail associations returned to members on their purchases in 1937 more than 189 million dollars.

United States.—In the United States the first known instance of consumers' co-operation occurred in 1845—only one year after its beginning in England when a tailor in Boston induced the members of his labor union to undertake joint buying of their household supplies and distribute them at the weekly meetings of the union. Another labor organization, the Knights of Labor, actively fostered co-operatives as part of its economic program during the early 1880's. Of the movement that has persisted to the present time, however, the farmers may be said to be the earliest proponents. Some of the Grange stores formed by the Patrons of Husbandry shortly after the Civil War still survive.

Since those early years consumers' co-operation in the United States has developed in a series of up-and-down movements corresponding roughly (but in reverse order) with prosperity and depression.

The movement has not yet attained the development in the United States that it has achieved abroad, but it is growing steadily, though slowly, in a number of directions. Not only is there an expanding retail movement, but co-operative wholesaling is now firmly established, and here and there productive activities are being undertaken. Local study groups, city-wide or country-wide councils of local associations, and regional leagues are doing various kinds of recreational and educational work—acting as channels for the exchange of ideas

and experience, issuing co-operative literature, furnishing speakers, sponsoring social events, running summer camps for children, youths, and adults, holding classes, and furthering in many ways the spread of the co-operative philosophy. The educational work is headed by a national league which serves the movement on a nation-wide scale.

The movement is also developing its own machinery to supply such centralized service as auditing, advice on merchandising methods, store planning, etc., and the technical training of both managers and clerks. Greater emphasis is being laid on quality of goods and on purchase by specifications, making use not only of established consumer services but to some extent of their own laboratory tests.

Probably the best-known form of consumers' co-operation in this country is the co-operative store handling groceries or general merchandise. As a matter of fact the store associations do form the largest group, and account for the largest proportion of total co-operative business. There are, however, many other lines of activity in which co-operation has made at least a start, and there is probably greater diversification in co-operative effort today than at any time in the history of the movement in the United States. Besides the great variety of businesses lumped together under the term «retail stores,» consumers' co-operatives include insurance associations, housing associations, credit unions, associations for the provision of medical care, burial associations, printing associations, bakeries, laundries, electricity associations, and various other types of service. A fair cross section of the consumers' co-operative movement and an indication of the relative importance of its component parts, is afforded by the tabulation made in 1936 by the United States Bureau of Labor statistics, Table IV:

Table IV—Estimated Number, Membership, and Business of Consumers' Cooperatives, 1936

Type of association	Number of associations	Number of members	Amount of business
Local Associations		*Individuals*	
Retail distributive associations	3,600	677,750	$182,685,000

[1]Actual figure, not an estimate; [2]gross income; [3]insufficient data to warrant computation of an estimate; [4]amount of loans made; [5]policyholders; [6]gross premium income; [7]does not include noncommercial federations, for which data were insufficient to warrant estimates; [8]items cannot be totaled because subgroups are not mutually exclusive.

Farmers' Co-operative Associations.—In July 1939 there were 10,700 farmers' co-operative marketing and (or) purchasing associations in the United States, with a total estimated membership of 3,300,000, according to a 1938–39 report of the Co-operative Research and Service Division of the Farm Credit Administration. The largest percentage (65.5) of these associations, as well as of the total membership (57.7), was in the 12 North Central States. Minnesota, Wisconsin, Iowa, and Illinois led all the States in number of associations, and Illinois, Minnesota, Iowa and Wisconsin led in membership. About 23.7 per cent of the associations marketed grain, more than 22 per cent manufactured and marketed dairy products, and about 24 per cent were engaged in purchasing farm supplies for their members. During the 1938–39 marketing season these associations did an estimated business of $2,100,000,000, the important States in volume being California ($232,870,000), Illinois ($222,900,000), New York ($144,860,000), Minnesota ($178,570,000), and Iowa ($120,310,000). The number of associations whose principal business was that of co-operative buying of farm supplies was 2,600 in 1938. These had 890,000 members and their volume of business was estimated at $335,000,000. Besides the associations organized principally for co-operative purchasing, about 40 per cent of the farmers' co-operative marketing associations do buying for their members of such supplies as fertilizers, dairy and poultry feeds, seeds, containers, coal, and petroleum products. The value of such purchases in 1938–39 was estimated at $107,000,000. The estimated total amount of purchasing done by both purchasing and marketing associations was more than $416,000,000; and the amount of marketing business done by both marketing and purchasing associations was estimated at $1,684,000,000. The total business by both groups in 1938–39 was thus estimated at $2,100,000,000.

Florence E. Parker,
United States Bureau of Labor Statistics.

CO-OPERATIVE BANKING. The idea of co-operative banking was conceived by Herman Schulze-Delitzsch and was first put into practice in 1849 at Eilenburg, Prussia. It grew out of his effort to rescue a number of carpenters and shoemakers from usury and to obtain money for them at fair terms upon their joint and several liability for buying the raw materials needed in their trades. The success of this venture led to various plans for people's banks and credit societies, based on co-operation for encouraging thrift in their neighborhoods and for extending financial assistance to their members for productive or provident purposes. See Banks and Banking; Co-operative Movement.

COOPERIA, koo-pē'rĭ-ą, a genus of plants of the *Amaryllis* family.. *(Amaryllidaceæ)*, so named in honor of Joseph Cooper, a curator of the Botanical Society of London. They are low herbs with coated bulbs and narrow grass-like leaves, with flowers somewhat resembling the atamasco lily. There are two known species in the United States, natives of the Southwest, and of Mexico. Drummond's Cooperia *(C. Drummondii)* grows on the prairies from Kansas

through Louisiana to Texas, New Mexico and Mexico. The flower is very fragrant, and because of its habit of blooming at night or in the early evening it is known as the evening star. The giant fairy-flower (*C. pedunculata*) is a favorite for cultivation, as it thrives well in ordinary garden soil, and if placed in a root-cellar in dry soil with an even temperature, will bloom again in the spring.

COOPERSTOWN, N. Y., village and seat of Otsego County, at the outlet of Otsego Lake (Cooper's Glimmerglass) and on the Delaware and Hudson Railroad, 90 miles west of Albany, alt. 1,240 feet. The site as early as 1769 was owned by George Croghan, Sir William Johnson's Indian agent, and in 1785 was purchased by William Cooper, father of James Fenimore Cooper, who made it the scene of the Leather-stocking Tales and who is buried here. In 1940 it celebrated its 150th anniversary, and in 1939 the centennial of baseball. The National Baseball Museum and Hall of Fame, Cooper's Statue, and the New York State Historical Association Museum are here. Cooperstown is a summer resort and has lumber and dairy industries. It has a mayor and council. Pop. (1940) 2,599.

CO-ORDINATES. See GEOMETRY; GEOMETRY, CARTESIAN; GEOMETRY, ELEMENTARY; GEOMETRY, LINE; GEOMETRY, MODERN ANALYTICAL.

CO-ORDINATION (Lat. «arranging in order,» «ranking together»), a physiological and psychological term, indicating the normal and harmonious operation of the muscles, especially the voluntary ones, in such actions as walking, motion of the arms and mastication. Co-ordination is dependent on the perfect and complete action of the sensory nerves, more especially those of the muscular sense and of the semicircular canals (See EAR), of the cerebellum and of the motor nerves and upon the healthy condition and proper interrelation of the muscles concerned. Its failure is usually due to affections of the brain or spinal column and is styled ataxia (q.v.).

COORG, koorg, or **KOORG,** British India, province bounded by Mysore on the east and northeast and the districts of South Canara and Malabar on the west; area, 1,593 square miles. Its greatest length from north to south is 60 miles, and greatest breadth from east to west 40 miles. It has a rainfall of 133 inches annually. The country in general is extremely rugged and covered with forests, in some parts abounding in sandal and other valuable woods, but in others overrun with jungle, the resort of elephants and beasts of prey; climate is temperate and healthy; soil fertile and in many parts well cultivated, yielding in abundance rice of superior quality. Great numbers of cattle are reared. The growing of coffee is an important industry, the bulk of the product being exported to France. The manufactures are insignificant. The province was added to the British dominions in 1834. The capital is Merkara. The old fortifications are interesting. High ramparts and deep ditches are so arranged as to be most effective in checking the advance of an enemy. Pop. (1931) 163,327.

COORNHERT, kôrn'hĕrt, **Dirck Volckertszoon,** Dutch poet and scholar; b. Amsterdam 1522; d. Gouda 1590. In 1562 he became secretary of the city of Haarlem and opposed the Spanish power, until he was imprisoned for a short time, and on his release forced to flee to Cleves and Xanten. In 1572, when the Dutch successfully revolted against Spain, he was made state secretary of the States of Holland. He was a well-known theologian, vigorously opposing the orthodox Protestant party. By his poetical writings, as also by his elegant translations from Boccaccio and the classics, he earned the title of «restorer of the Dutch language.» His poetical works include 'Abrahams rytgang' ('The Death of Abraham'), and 'Comedie van de blinde van Jericho' ('Comedy of the Blind Man of Jericho'). His prose works include 'Zedekunst, dat is wellevens kunst' ('Ethics, that is, the Art of Right Living') which appeared in 1586, and deserves special mention. Consult Moorres, 'D. V. Coornhert de Libertijn' (1887).

COOS BAY, an indentation on the coast of Oregon in lat. 43° 45′ N. in Coos County. It extends into the land about 10 miles and is only one mile in width, thus making it a safe harbor. Marshfield and North Bend are on Coos Bay.

COOSA, koo'sa, **RIVER,** in Floyd County, in the northwestern part of Georgia, is formed by the junction of the Ostanaula and the Etowah rivers; it flows southwest into Alabama and about eight miles north of Montgomery it unites with the Tallapoosa River and forms the Alabama. Its length is about 350 miles. It is navigable for boats of light draft from its mouth to Wetumpka and from Greensport to Rome, Ga., and drains an area of 10,000 square miles.

COOSY, koo'sē, or **KUSI,** a river of India, rising in Nepal and flowing first south-southeast to the British frontier, and then nearly due south to the Ganges. It is very rapid and difficult to navigate. It is noted for its destructive floods. Its total length is about 325 miles.

COOT, a strictly aquatic bird of the genus *Fulica,* sub-family *Fulicinæ* and family *Rallidæ,* also called water-hens and crow-ducks. About 10 species are known, distributed throughout the world; but mostly in South America, which has six. The American coot, *F. americana,* is abundant throughout North America, breeding wherever found and resident in the South. Its appropriate habitat is shallow reedy ponds, and sluggish streams. The nest is a disordered heap of reeds or similar material in or near the water, in a hollow of which 8 to 12 eggs, clay-colored, with brown spots, are deposited. The length of the bird is 14 to 16 inches, but the body is remarkably compressed, and the feet are nearly unique in the lobate webbing of the toes. The color is generally sooty slate, with the lower belly and some other parts white and the bill red at tip and base. The coot is much sought by gunners about the interior lakes. The European coot (*Fulica atra*) is a closely similar bird, slaty in color, with a bare patch on its head, whence the name bald coot; it is found throughout Europe and in Asia.

COOTE, SIR **Eyre,** British military officer: b. County Limerick, Ireland, 1726; d. Madras, 26 April 1783. He entered the army at an early age, and from 1754 to 1762 served in India. It was by his arguments that Clive was induced to risk the battle of Plassey, and for his services in this and other engagements, Coote was

in 1759 given the command of the newly raised 84th regiment. In this year he gained the great victory of Wandiwash; and his capture of Pondichéry in 1761 completed the downfall of the French in India. Coote returned to England, and was knighted in 1771. In 1779 he assumed the command-in-chief in India, with the rank of lieutenant-general, and in 1781 he routed Hyder Ali at Porto Novo.

COPAIBA, kō-pā'ī-ba, the oleoresin of *Copaiba Langsdorfii* and other species of copaiba. Of these at least 16 are known to give this drug, and seven are known to yield a product that is sent to the United States. Oleoresin copaiba comes mostly from Brazil and the West Indies; it is found in special secretory passages in the wood from which it is obtained by deep gashs cut into the tree, much as turpentine is obtained from pine trees. The oleoresin flows in a steady stream, one tree often yielding as much as from 10 to 15 gallons. Copaiba as it comes into the market varies much in age and variety. The finer sort of Pará copaiba is a thick liquid, clear, somewhat resembling Canada balsam. It may be darker, sometimes resembling sherry. It has a specific gravity of .92, does not mix with water, but is soluble in ether. Distilled with calcium hypochlorite it yields chloroform. Copaiba oil has a peculiar aromatic odor which is extremely disagreeable. The chemical composition of copaiba is extremely complex. It contains at least from 40 to 80 per cent of oil and a large amount of resin, which consists largely of copaivic acid ($C_{20}H_{30}O_2$). Oxycopaivic acid and metacopaivic acids are also found. The action of copaiba is largely exerted on the genito-urinary system, where it acts as a stimulant diuretic and irritant, and is particularly useful in diseases of the bladder, urethra and mucous membranes of the pelvis and of the kidneys. It may be used in bronchial affections also, but is rarely thus employed because of its disagreeable taste and because it very frequently causes an eruption. It is usually administered in gelatine capsules. Its chief commercial use is as a vehicle in oil painting and as a varnish.

COPAIS, kō-pā'is, formerly a lake of Greece, in Bœotia, fed mainly by the river Cephissus. In 1886 a French company undertook to drain off again the water, and after working for some time they were superseded by an English company. In 1894 the work was completed and about 60,000 acres of good soil was reclaimed. Consult Curtius, 'Die Deichbauten der Minyer.' See BŒOTIA.

COPAL, a group of very hard resins derived from a great variety of plants both recent and fossil, the botanical names of which are not determined beyond doubt. Its chemical composition is: Carbon 78 to 80.5, hydrogen 8.7 to 10.5 and oxygen 9 to 10.7 per cent. The harder sorts are chiefly derived from fossil sources. In the recent state the resins have been obtained from species of *Hymenæa verrucosa* and *Guibourtia* from Africa, South America and the West Indies. Copal occurs for the most part in irregular pieces. As found in nature all of the fossil gums are covered with a crust of oxidized gum, the result of fossilization. This must be removed by chipping or scraping, or by the aid of alkalis, to prepare the gum for market. The Zanzibar and Angola varieties then have a characteristic «goose-flesh» appearance. Copal is without taste or odor; it has a conchoidal fracture, and a tendency to break into six-sided fragments. It is used in the manufacture of varnish, its particular value arising from its hardness, which is about 3 of the mineral scale. It can be dissolved in aniline oil. The softer varieties are of recent origin, and are known as «spirit copals» because soluble in alcohol or turpentine.

COPALCHI BARK, a bark resembling cascarilla bark in its properties, and produced by a shrub of the same genus, *Croton Pseudochina,* a native of Mexico and of Central America. The bark comes to Europe in quills a foot or two in length, and has a thin corky epidermis. Copalchi bark is much used as a substitute for cinchona in Mexico, where it goes by the name of *Quéna blanca,* and is imported, though not to a large extent, in Europe. It contains a minute proportion of a bitter alkaloid resembling quinine, and is somewhat weaker than cascarilla bark.

COPARCENARY, in law, partnership in inheritance; a joint heirship in which each is entitled to a distinct share of the benefits, while the property remains undivided. It commonly arises from the custom of dividing equally among coheiresses the property of a man who dies intestate; but even in England, where the eldest son is usually sole heir, local custom may create coparcenary among male heirs.

COPE, Charles West, English painter: b. Leeds, 28 July 1811; d. Bournemouth, 21 Aug. 1890. He studied at the Royal Academy and in Italy, and first exhibited at the Academy in 1831. In 1843 he gained a prize of £300 for his picture, 'The First Trial by Jury'; in 1844, by his fresco, the 'Meeting of Jacob and Rachel,' he secured the commission for one of six frescoes for the House of Lords, producing accordingly 'Edward the Black Prince Receiving the Order of the Garter.' Altogether he executed eight frescoes from English history of the 17th century for the House of Lords, while his other works were numerous, the subjects being historical, romantic or domestic. Of these some of the most important are 'Nereids' (1836); 'Cotter's Saturday Night' (1843); 'Last Days of Wolsey' (1848); 'King Lear' (1850); 'Milton's Dream' (1850); 'Pilgrim Fathers' (1857); 'Evening Prayer' (1860); 'Spring Flood' (1865); 'Shylock and Jessica' (1867); 'The Disciples at Emmaus' (1868); 'Yes or No?' (1873); 'Taming of the Shrew' (1874); 'Anne Page and Slender' (1875); 'Selecting Pictures for the Royal Academy Exhibition' (1876); 'Bianca's Lovers' (1877); and 'Far away Thoughts' (1881). His etchings have also been much admired. He also illustrated the de luxe editions of Gray's 'Elegy' (1874); Goldsmith's 'Poetical Works' (1845); Thomson's 'Seasons,' etc. He became A.R.A. in 1843 and R.A. in 1848. Consult Cope, C. H., 'Reminiscences of C. W. Cope' (London 1891).

COPE, Edward Drinker, American zoologist and palæontologist: b. Philadelphia, Pa., 28 July 1840; d. there, 12 April 1897. Oliver Cope came to this country from Wiltshire, England, about 1687 and settled on Naaman's Creek in the northernmost part of the State of Delaware. Oliver's grandson, Caleb, a member of the Society of Friends, was burgess of Lancas-

ter, Pa., in 1776, and incurred the indignation of his fellow-townsmen for offering the hospitalities of his house to Captain (afterward Major) André and other British prisoners captured at Saint John's, Canada, by General Montgomery. Caleb's son, Thomas Pim Cope, settled in Philadelphia, and established the Cope packet line, trading between that city and Liverpool. Thomas Pim Cope's son Alfred married Hannah Edge and was the father of the subject of this sketch.

During the first seven years of Edward's life he was educated at home, and gave early proofs of a restless inquisitiveness and an accuracy of reasoning on what he had observed, very rare in so young a child. At 13 he entered the Friends' School at Westtown, Chester County, Pa. As a young man of 18 he announced to his family that he was to be a naturalist.

His father tried to make a farmer of him, and for this purpose gave him a farm near Coatesville, Pa. He learned much of the flora and fauna of this region, but revolted at the thought of settling down to this monotonous life. He longed to grapple with the larger problems of biology, and broadly hints this in a letter of 1858: «Dr. Leidy is getting up a great work on comparative anatomy.» . . . «Such a work will be very useful to those who want to go to the bottom of natural history; it is an interesting study, too, to notice the modification in form, the degradations, substitutions, etc., among the internal organs and bones. The structure, forms and positions of the teeth, too, are interesting to notice, so invariably are they the index of the economy and the position in nature of the animal.»

In 1859 he published his first paper on the 'Primary Division of the Salamandridæ.' He became a member of the Academy of Natural Sciences of Philadelphia in 1861. He had had his wish to attend Leidy's lectures, and this same year he spent some time with Gill, Kennicott, Meek and Horatio Wood in the museums of the Smithsonian Institution at Washington. He greatly admired professors Henry, Baird and Arnold Guyot. He was astounded that Guyot believed in the resurrection of the body. He published 6 scientific papers in 1860; 9 in 1861; 13 in 1862; 4 in 1863; 5 in 1864; 10 in 1865; 11 in 1866. These were almost exclusively printed in the *Proceedings* of the Academy of Natural Sciences and were largely on herpetology. In 1866 he became a member of the American Philosophical Society, and thenceforward published largely in this society's proceedings. Altogether, counting his editorials in the *American Naturalist,* and five posthumous publications, his life yielded 1,281 separate papers on scientific subjects. The following statement of his work is taken from Prof. Henry F. Osborn's article in *Science* for 7 May 1897.

As early as 1868 he laid the foundations for five great lines of research on the following subjects: Fishes, Amphibians, Reptiles, Mammalia and Philosophy. He unconsciously followed Lamarck in ascribing to conscious effort the adaptive changes in species, and this at the age of 28. In 1869 he struck the keynote of all his later evolution in the sentence, «Intelligent choice may be regarded as the originator of the fittest, while natural selection is the tribunal to which all the results of accelerated growth are submitted.» He accepted the term Neo-Lamarckian as properly describing his position, which was that, while very many specific characters are adaptive, few generic characters are so, but these latter are the results of the acceleration or retardation of one plan of development preordained by the Creator. As in the case of Huxley, Haeckel and many other naturalists of the last century, his career started in zoology, but led inevitably to palæontology, as it always must with a man of research so broad of view. Osborn says Cope's work in ichthyology would alone have given him high rank among zoologists. Baur says no naturalist ever published so many papers on the taxonomy, morphology and palæontology of the amphibia. His work on the Mammalia and Reptilia was immense. At the time of his death Cope had personally named and described 1,115 out of 3,200 known species of fossil vertebrates of North America, or 34.8 per cent.

He was elected professor of natural science at Haverford College in 1864; was made a member of the National Academy of Science in 1872; received the Bigsby gold medal from the Geological Society of London in 1879; was elected to membership in the Imperial Society of Moscow in 1886; received the degree of Ph.D. from Heidelberg University on the occasion of the celebration of its 500th anniversary, and was elected professor of geology and palæontology at the University of Pennsylvania the same year. In 1891, on motion of Dr. Leidy, he was awarded the Hayden memorial medal. He was president of the American Society of Naturalists in 1895, and president-elect of the American Association for the Advancement of Science at the time of his death. For his titles and those of all of Professor Cope's publications, consult 'Catalogue chronologique des publications de E. D. Cope, Annales de la société géologique de Belgique t. XXIX Bibliographie, Liége, 1902'; and the 'Alphabetical Cross Reference Catalogue of the Works of E. D. Cope'; 'Memorias y Revista de la Sociedad Antonia Alzate,' Mexico 1902; both by Dr. Persifor Frazer.

PERSIFOR FRAZER.

COPE, Henry Frederick, American author and editor: b. London, Eng. 17 June 1870; d. 3 Aug. 1923. Educated at the Government Boy's School, Enfield, the Department of Sciences and Arts, South Kensington, London, and by private tutors. He came to the United States in 1891, studied theology at the Southern Baptist Theological Seminary, and was ordained to the Baptist ministry in 1893. He subsequently held pastorates in Rochester, N. Y., 1894–95; Plano, Ill., 1895–98; and Dillon, Mont., 1898–1903. In 1903 he was engaged in teaching and in special literary work in Chicago. For eight years he was religious editor of the Chicago *Daily Tribune,* and contributed weekly a column to a syndicate embracing the leading daily papers and was on the staff of *The World To-Day, The Sunday School Lines, Service, the Country Gentleman,* etc. He became assistant secretary in 1905, and in 1907 general secretary of the Religious Education Society, in which capacity he visited and spoke in nearly all educational institutions, visiting practically every State in the Union every year. He was editor of *Religious Education* from its founda-

tion in 1906. He edited 'Adams Primer on Teaching' (1905); 'The Aims of Religious Education' (1906); 'The Materials of Religious Education' (1907); Education and National Character' (1908) and published: 'The Bonanza Bible Class' (1904); 'Sunday School Management' (1905); 'Hymns You Ought to Know' (1906); 'The Modern Sunday School in Principle and Practice' (1907); 'Levels of Living' (1908); 'The Friendly Life' (1909); 'The Efficient Laymen' (1910); 'The Evolution of the Sunday School' (1911); 'Efficiency in the Sunday School' (1912); 'Religious Education in the Family' (1915). He received the honorary degree of A.M. from Oberlin College in 1911, and that of D.D. from Washburn College in 1911.

COPE, Sir **John,** English general: d. 28 July 1760. Having been made a knight of the Bath, in 1742 he commanded the troops sent to the assistance of Maria Theresa. On the landing of Prince Charles Edward in 1745, Cope was appointed commander-in-chief of the government forces in Scotland. After a fruitless march to the Highlands, he returned with his troops by sea to Dunbar, and on 21 September was totally defeated at Prestonpans by the Scottish troops under Charles Edward Stuart, the "Young Pretender." His defeat is celebrated in the Jacobite song, 'Hey, Johnnie Cope, are Ye Waukin' Yet?' In 1732 he headed a committee which made a famous report on revenue funds and smuggling.

COPE, Thomas Pym, American merchant: b. Lancaster County, Pa., 26 Aug. 1768; d. Philadelphia, Pa., 22 Nov. 1854. He began importing goods in his own vessels in 1807, and in 1821 established the first line of packets between Philadelphia and Liverpool. He was held in great respect by his fellow-townsmen, who elected him to many places of trust and honor. During the yellow fever epidemic of 1793 he stayed in the city to aid its victims, and during the smallpox outbreak in 1797 carried food to the houses of those taken with the disease, and in other ways cared for them. He was an executor of Stephen Girard's will; secured the estate of Lemon Hill as a park for the city; and was active in the construction of the Pennsylvania Railroad. The introduction of the Philadelphia water supply from the Schuylkill, the completion of the Chesapeake and Delaware Canal, the construction of the Pennsylvania Railroad and the establishment of the Mercantile Library were largely due to his efforts. In 1807, he was elected to the State legislature.

COPE, an article of ecclesiastical vesture in the Roman Catholic Church. It is a voluminous cloak reaching nearly to the feet, opening in front, and with a semi-circular cape or hood behind. It is usually of silk material, embroidered, or of cloth of gold. It is worn by the celebrant in certain functions, as processions and benediction. The cope is not, like the chasuble (q.v.), reserved to priestly use; it is worn also in solemn processions by the clerics who attend the celebrant, and by the cantors in church services. See Costume, Ecclesiastical.

COPECK (Russian, "a lance"), a Russian copper coin, so called from the impression of Saint George bearing a lance. It is the oldest form of coin in Russia and superseded furs as a medium of exchange. The coin is the hundredth part of a silver ruble, and made now either of copper or bronze metal. It varies in value and one copeck or kopeck is now worth about one-half of a cent. See Coins, Foreign, American Equivalent of.

COPELAND, Edwin Bingham, American botanist: b. Monroe, Wis., 30 Sept. 1873. He was graduated at Leland Stanford Junior University in 1895, and also studied at the universities of Leipzig, Halle, Wisconsin and Chicago. In 1897–98 he was assistant professor of botany at Indiana University and held the same position in the University of West Virginia in 1899–1900. In 1901–03 he was instructor in botany at Leland Stanford University, he was botanist to the Philippine government, 1903–08; superintendent of the Philippine Agricultural School 1908–09 and dean of the College of Agriculture and professor of plant physiology in the University of the Philippines 1909–17. He published 'Philippine Agriculture' (1908); 'The Cocoanut' (1914); 'Rice' (1924); 'Fiji Ferns' (1929); and 100 articles on botanical research.

COPENHAGEN ("Merchants' Haven"), Denmark, the capital, situated on the shore of the island of Zealand, in the sound, which is here about 12 miles broad; an outlying portion, Christianshavn, stands at the north end of the island of Amager or Amak, which is separated from Zealand by a narrow arm of the sea. The channel forms a fine large harbor, which is bridged over at two points to connect Christianshavn and the main part of the city. The fortifications on the land side have been removed since 1863; so that the city has now practically incorporated the suburbs Osterbro, Nörrebro, Vesterbro and Frederiksberg and occupying an area of 31 square miles. To counterbalance the expected injury to the city's commerce from the opening of the Baltic Canal, a great free port, free from customs dues, was constructed in 1890–94 to the north of the harbor. The business quarter stretches from the harbor in a northeasterly direction toward the principal and central square, Kongens Nytory, which forms the focus of the life of the city. Farther north and east of this point lies the aristocratic quarter, with the handsome Amalienborg Square and its royal and ministerial palaces; this district is bounded on the extreme north by the citadel and the adjoining public gardens and walks on the shores of the sound.

Among its few buildings of historical interest or intrinsic beauty, the Metropolitan cathedral church, known as Vor Frue Kirke, rebuilt after the bombardment in 1807, possesses statues of Christ and the apostles and a baptismal font, designed and in part executed by Thorwaldsen. Trinitatis-kirke is remarkable for its round tower, which is ascended by a winding causeway instead of steps. Holmens'-kirke contains interesting monuments to the great naval heroes, Juel and Tordenskjöld. An English church, built at a cost of $49,000, was consecrated in 1887. The royal palace, called Christiansborg, was rebuilt between 1794 and 1828, but was never remarkable for architectural beauty. The principal part of the vast building was destroyed by fire in 1884, when many precious works of art were destroyed. Happily most of the pictures in its great art gallery were

saved. The castle of Rosenborg (1610–24), where the regalia are kept, contains interesting collections of objects of art; and the palace of Charlottenborg (1624) is now used as an academy of arts. Copenhagen is the centre, not only of Danish, but northern literature and art, and is the seat of a number of societies for the advancement of these in all their branches, among which are the Royal Society, founded in 1742; and the Royal Society of Northern Antiquaries, founded in 1825. A magnificent national theatre was built in 1874. The royal library contains over 600,000 volumes, besides great treasures of Sanskrit and other MSS. The Museum of Northern Antiquities in Prindsens Palais is unrivaled in its kind, having been made what it is mainly by Worsaae. The Thorwaldsen Museum, opened in 1846, consists of works of art by that sculptor himself, and others left by him to the Danish nation, for which a separate building has been erected. There are statues of several of the Danish kings, of Tycho Brahè and of the poets. The city is governed by a body of magistrates nominated by the king, and a municipal council of 42 members. About 50 per cent of the trade of Denmark passes through Copenhagen. The chief exports are grain, rape-seed, butter, cheese, beef, cattle, wool, hides, bones and grain-spirit. Porcelain, pianos, clocks, watches, mathematical instruments, textiles, chemicals, sugar, beer and tobacco are manufactured. Copenhagen is the seat of a United States consul-general.

About the middle of the 12th century Copenhagen was but a fishing village, in the neighborhood of which Bishop Axel, or Absalon, built a castle. In 1254 the village obtained the privileges of a town, and in 1443 King Christopher made it the capital of the kingdom. It was several times attacked by the Hanseatic League; was besieged by the Swedes in the 17th century; was bombarded by the English, Dutch and Swedes in 1700; suffered grievously by fire in 1728, 1794 and 1795; witnessed a great sea-fight in its roads on 2 April 1801, when the English, under Sir Hyde Parker, with Nelson as his second in command, destroyed the Danish fleet; and (to prevent the Danish fleet from falling into the power of Napoleon), was bombarded by the English from the 2nd to the 5th of September 1807, when great destruction was wrought, and hundreds of persons lost their lives. Pop. of Copenhagen (Kjöbenhavn), 587,-150; with suburbs, 731,496. Consult Rostock, X., 'Copenhagen, the Capital of Denmark, and Its Environs' (1922); Nielsen, 'Kobenhavns Historie og Beskrivelse' (6 vols., 1887–92).

COPENHAGEN, University of, founded in 1478, by Christian I; destroyed during the civil wars; rebuilt by Christian III in 1539; destroyed by fire in 1728; rebuilt by Christian VI in 1732, and organized as at present in 1788. This is the only university in Denmark and one of the best in the northern part of Europe. It is supported partly by the government and partly by endowment; instruction is free to both sexes. At present there are enrolled 4,900 pupils, and the library contains 400,000 volumes. It possesses also a large collection of Persian MSS., another of the Northern MSS. Connected with the university, which has five faculties, are a surgical academy, an observatory, a botanical garden, a zoological museum and a polytechnic institution.

COPEPODA, an order of small Crustacea, characterized by the following aggregate of features: Animal consists of about 16 segments; limbs mostly two-branched; no carapace; development by the addition of new segments behind to a Nauplius larva. Except in the Branchiura, the simple eye of the Nauplius is the definite eye of the adult. Many widely different copepods are parasitic. The Branchiura are ectoparasites on various species of fish. The remaining copepods are divided into the Gymnoplea, in which the division between the front and hind portions of the body falls immediately in front of the genital openings, and behind the fifth thoracic feet, which are modified in the male into a copulatory organ, and the Podoplea, where the boundary falls in front of the fifth thoracic segment. The phosphorescence of the sea is largely due to certain small Gymnoplea. Certain of the Podoplea, forming the family Manstrillidæ, have a very complicated development, for an amorphous parasitic stage intervenes between a free-swimming Nauplius and a likewise free-swimming adult. Consult the article on the Crustacea by Smith and Weldon in volume IV of 'The Cambridge Natural History' (London 1909); the article on the Crustacea by W. T. Calman in Part VII; third fascicle in Sir Ray Lankester's 'A Treatise on Zoology' (London 1909); the article on the Crustacea in volume III of A. Sedgwick's 'A Student's Text-Book of Zoology' (London 1909).

COPERNICAN SYSTEM, The, an epoch-making reversal of man's ideas as to the place of the earth in the universe and the motions of the heavenly bodies, the full details of which were completed by Nicolaus Copernicus, a Polish astronomer, in the year 1530. Prior to the work of Copernicus, it was universally held that our earth is a fixed and immovable body, situated at the centre of the universe, about which all heavenly bodies, including the sun and the fixed star, are in revolution. To account for the apparently complicated motions of the planets, which sometimes are moving eastward among the stars and sometimes are moving westward (or «retrograding»), it had been necessary to suppose that each planet is moving about the circumference of a small circle (called the «Epicycle»), the centre of which pursues a larger circular path about the sun. This older system, devised as early as 140 A.D. by Claudius Ptolemy (q.v.), an Egyptian astronomer, held its place as the true conception of the universe for upward of 14 centuries.

In the Copernican system it was clearly shown that the diurnal motion of the stars (their rising and setting) could be accounted for by assuming that the earth rotates on an axis with a uniform angular velocity, and, further, that the complicated displacements of the planets among the stars could very nearly all be explained by the assumption that the earth and all of the other planets are revolving about the sun in circular orbits of which, however, the sun does not occupy the exact centre. The true paths, however (as we now know), are ellipses, and not exact circles. (See SOLAR SYSTEM). It was therefore necessary for Copernicus to retain in his system a few small

«Epicycles» to account for certain small outstanding disagreements between the predicated and the observed motions.

So complete an overturning of man's conception of the place and importance of the earth naturally by no means met with immediate acceptance. It was, in fact, fully a century after the death of Copernicus (in 1543), before the reasonableness and simplicity of the new theory finally overcame the older, very artificial and complicated system of Ptolemy. At the present time many direct observational proofs are available that the earth is revolving about the sun (see PARALLAX, ABERRATION, The DOPPLER PRINCIPLE, etc.), so that the essential truth of the Copernican theory is no longer open to question.

COPERNICUS, or KOPPERNIGK, Nicolaus, Polish astronomer: b. Thorn, Poland, 19 Feb. 1473; d. Frauenburg, East Prussia, 24 May 1543. His father was a Pole and his mother a German. From a school at Thorn Copernicus went to Cracow, where he studied medicine, theology, mathematics and astronomy. The fame of Peurbach and Regiomontanus, the restorers of astronomy in Europe, excited his emulation. In 1496, at the age of 23, he went to Italy, and at Bologna resided two years, studying canon law and astronomy. In 1497, while in Italy, he was appointed a canon of the cathedral of Frauenburg. In 1500 he went to Rome, where he lectured on mathematics and astronomy. Subsequently he studied medicine at Padua, and canon law at Ferrara, where he graduated as doctor in this subject. He returned to Prussia in 1505, and lived for some years at Heilsberg, but his subsequent life was mostly spent at Frauenburg.

He now applied his whole strength to the study of astronomy, which at this time was dominated by the system of Claudius Ptolemy. Copernicus doubted whether the motions of the heavenly bodies could be so confused and so complicated as this hypothesis would make them. He found that some of the ancient Greeks had thought of the possibility of a motion of the earth. This induced him to examine the subject more fully, and he came to the following conclusions: That the sun was the centre of the system; that the earth was a planet like Mars and Venus; and that all the planets revolve round the sun in the following order: Mercury in 87 days, Venus in 224, the Earth in 365, Mars in one year and 321 days, Jupiter in 11 years and Saturn in 29 years. Although Copernicus knew that the planetary orbits are not circles having the sun in the centre, he was not able to determine exactly their form. This was reserved for Kepler, who completed what may be called the natural history of the subject, and stated his three celebrated laws in the end of the 16th century. Thus Copernicus stands, as it were, upon the boundary-line of a new era. He commences his labors at a time when the belief in the immobility of the earth is universal. He conceives the idea of its motion, and pursues it with unwearied diligence, not for a few years, but through the greater part of his life, constantly comparing it with the appearances in the heavens. He at last confirms his idea, and thus becomes the founder of a new system of astronomy. All this he did a hundred years before the invention of telescopes, with imperfect wooden instruments on which the lines were often only marked with ink. His great countryman, Kepler, has described his character in the following words: «Copernicus, vir maximo ingenio, et quod in hoc exercitio magni momenti est, animo liber.» In his celebrated work, dedicated to the Pope, Paul III, 'De Orbium cœlestium Revolutionibus,' libro vi (completed in 1530, although first published at Nuremberg 1543, folio; later editions appeared at Basel 1566, at Amsterdam 1617, at Warsaw in 1851, at Berlin in 1873), his system is developed.

Besides his principal work, we have also by him a work on trigonometry, 'De Lateribus et Angulis Triangulorum.' The first biography of Copernicus was written by the mathematician Gassendi (1654), and for 200 years this work served as the basis of all subsequent biographies of the great astronomer; but in more recent times the labors of Prowe and others have helped us to a better acquaintance with the facts of his life. Count Sierakowski erected a monument to his memory in Saint Anne's Church at Cracow, with this inscription: «Sta, sol, ne moveare» (Stand, Sun, do not move). Thorwaldsen, one of the greatest sculptors of our time, executed a colossal statue of Copernicus for the city of Cracow, which is one of the noblest specimens of modern art. Another statue of him by F. Tieck has been erected in his native town. Consult Bertrand, 'Les fondateurs de l'astronomie moderne' (Paris 1865); Bryant, 'History of Astronomy' (London 1907); Curtze, 'Nicolaus Copernicus' (Berlin 1899); Czynski, 'Kopernik et ses travaux' (Paris 1847); Flammarion, 'Vie de Copernic' (ib. 1872); Gassendi, 'Vita Nicolai Copernici' (The Hague 1652); Muller, 'Nikolaus Copernicus, der Altmeister der neueren Astronomie' (Freiburg 1898); Prowe, 'Nicolaus Copernicus' (3 vols., Berlin 1884), the standard biography; Wolf, 'Geschichte der Astronomie' (Munich 1877); id., 'Handbuch der Astronomie, ihrer Geschichte und Litteratur' (2 vols., Zürich 1893).

COPHA, a racially and linguistically distinct Indian family which formerly occupied extensive territory in California from far south to Mount Shasta in the north. The Copehan language was well developed and harmonious; but their political and social systems were little, if any, in advance of those of the other Indian races of California. There was considerable difference between the language (dialectically) and customs of the Cophas of the south and those of the north of California. Even the people of the 20 or more important villages of Cophas differed dialectically. There were two distinct branches of the Cophas or Copehan family, known as the Patwin and the Wintun. The Government Agricultural Commission appointed in the fifties to adjust the claims of the Indians and Mexicans overlooked a small section of the Cophas then living on what is now known as Warner's Ranch near Los Angeles, in southern California, and their lands were sold without a hearing. They refused to leave their home, but in May 1901 the Supreme Court confirmed the rights of the white claimants. In May 1903 they were moved by the government to a fertile tract of land

in the Valley of Pala, on the San Luis Rey, where they were subsequently joined by other members of the tribe.

COPHETUA, an African king of legend and ballad verse who married the beggar maid, Penelophon. Shakespeare in alluding to Cophetua calls the maid Zenelophon. There is a well-known poem by Tennyson on the subject, called the 'Beggar Maid,' and the story is also told in Percy's 'Reliques.'

COPIAPO, kō-pē-ä-pō', or **SAN FRANCISCO DE LA SELVA,** Chile, the capital of the province of Atacama, centre of an important mining district containing machine shops and smelting works. Silver and copper are the chief minerals obtained, but gold also is found. There is a railway connecting it with its port, Caldera. In 1819 and 1822 it was destroyed by earthquakes; and in 1851 it was again seriously damaged. The principal points of interest are the parish church; a bronze statue of Juan Godoy, the discoverer of the Chañarcillo silver mines; and also a provincial high school, a mining school and a public library. Pop. about 12,000.

COPLAS DE MANRIQUE, kōp'las dę män-rēk'ē. This is the modest title of an elegiac poem by Jorge Manrique (1440–79), generally considered the most eminently successful of the Spanish lyric poets of the 15th century. This success is due to the *coplas,* the more distinctive title of which is 'Coplas de Manrique por la muerte de su padre' ("Manrique's Couplets on the death of his father"). The elegy consists of about 500 lines divided into 42 *coplas,* or stanzas, in the old Spanish measure and manner, called *redondillas con quebrados* (quatrains with a short line in every third place). The poem was first published in 1492, 16 years after it was written, when Manrique's father, the Maestro de Santiago, died (1476), in whose honor it was composed. Spanish devotional poetry contains many exquisite gems, and the coplas are rightly placed among them. Grief for the death of his father has brought to the poet's mental vision a vista of the spiritual world, and a realization of the vanity of material things. The impression of many of the lines is ineffaceable. In 1833 appeared the remarkably fine English rendering by Longfellow, in which the versification, spirit and even wording of the original are followed as closely as possible. Besides its inherent charm, Manrique's poem is noteworthy in its independence of the three dominating poetic influences of the day, the artificial court verse, the Italian influence and that of the Renaissance.

There have been many editions of the Spanish text of the poem since the 1492 edition, notably the Madrid edition of 1799 with a gloss, contained in 'Proverbios de don Iñigo López de Mendoza, Marqués de Santillana, y las coplas de don Jorge Manrique, todo con sus glosas, por D. Fermin Villapando'; the critical edition published by R. Foulché Delbosc (Madrid 1902; Vol. XI of the 'Biblioteca hispanica'); also translations into foreign languages and commented versions. Many, if not all, of the coplas appear in annotated anthologies. (Cf. J. D. M. Ford's 'A Spanish Anthology,' Boston 1901, pp. 43–59). The entire text of the poem will be found in 'Antología de poetas líricos castellanos ordenada por D. Marcelino Menéndez y Pelayo.'

JAMES GEDDES, JR.

COPLAY, Pa., a borough of Lehigh County on the Lehigh River near Allentown; alt. 299 feet. Pop. (1940) 3,109.

COPLEY, John Singleton, American painter: b. Boston, Mass., 3 July 1737; d. London, England, 9 Sept. 1815. He was of Irish parentage and received his early training in engraving from his stepfather, Peter Pelham, a mezzotint engraver. In painting he was practically self-taught. His talent for drawing developed at an early age, and in 1760 he sent anonymously to Benjamin West in England a portrait called 'The Boy and the Flying Squirrel,' which, when exhibited, was highly praised by the best English artists of the time. In 1769 he married the daughter of a wealthy Boston merchant, and became the recognized painter of Boston society. In 1774 he sailed for England, visited Italy and settled in London, where he rose rapidly in popularity as a portrait painter, within a few years being elected an associate member and full member of the Royal Academy. Some of his most celebrated paintings are portraits of the English royal family; the 'Death of Lord Chatham,' now in the London National Gallery; 'Siege and Relief of Gibraltar,' in the council chamber of the Guildhall; 'Major Pierson's Death on the Isle of Jersey'; 'Surrender of Admiral De Winter to Lord Duncan'; 'Charles I Demanding the Five Impeached Members in the House of Commons'; 'The Red Cross Knight'; 'Mrs. Derby as Saint Cecilia.' His principal American portraits are those of Samuel Adams and John Hancock, in the Boston Art Museum; Mrs. Ford, in the Boston Athenæum; Mrs. Thomas Boylston and others, in Harvard Memorial Hall; Lady Wentworth and Mrs. Robert Harper, in the New York Public Library; Robert Izard and his wife, painted in Rome, now in the Boston Art Museum; the Copley Family and John Quincy Adams, in the Boston Art Museum. His son, Lord Chancellor Lyndhurst, made a notable collection of his father's works, which was dispersed at public sale in 1864. Consult Perkins, 'Life of J. S. Copley' (Boston 1873); Amory, 'Life of J. S. Copley' (Boston 1882); Isham, 'History of American Painting' (New York 1905).

COPLEY, John Singleton (1772–1863). See LYNDHURST, BARON.

COPPEE, kŏp-pā, **François Édouard Joachim,** French poet and dramatist: b. Paris, 12 Jan. 1842; d. Paris, 23 May 1908. He was librarian of the Senate, and keeper of the records at the Comédie Française 1878–84. He became a member of the French Academy in 1884, and an officer of the Legion of Honor in 1888. From 1880 to 1884 he was the dramatic critic of *La Patrie.* Coppée was an accomplished artist and a skilled craftsman, although a trifle affected. His verse lacks true inspiration, but may be characterized as finished poetical prose. He is par excellence the poet of the humble classes. Chief among his plays are 'Le passant' (1869); 'Fais ce que tu dois' (1871); 'Le luthier de Crémone' (1877); 'La guerre de cent ans' (with d'Artois) (1878); 'Madame de Maintenon' (1881); 'Severo Torelli' (1883); 'Les Jacobites' (1885). An edition of

his dramas in four volumes appeared (1873–86). Among his poems may be named 'Les intimités' (1868); 'Poèmes modernes' (1869); 'Une idylle pendant le siège' (1875); 'L'exilée' (1876); 'Lesmois' (1877); 'Le naufrage' (1878). He has also published short stories including 'Le coupable' (1896), and 'La bonne souffrance' (1900) and a collection of essays 'Mon franc parler' (1894). Consult Lescure, 'F. Coppée, l'homme, la vie et l'œuvre' (Paris 1889); Gaubert, 'François Coppée' (it. 1906); Druilhet, 'Un poète français: François Coppée,' (Paris 1902); Delmont, 'Trois illustres conquêtes de la foi: Coppée, Brunetière, Bourget' (1905).

COPPENS, Charles, American clergyman and educator: b. Turnhout, Belgium, 24 May 1835. He was educated at the Jesuit College, Turnhout, and the Jesuit scholasticates at Saint Louis, Mo., and Fordham, N. Y. In 1853 he entered the Society of Jesus, was ordained to the priesthood in 1865, and at various times was professor of the classical languages, of philosophy and the history of philosophy in the Jesuit colleges at Saint Louis, Cincinnati, Detroit, Omaha and Chicago. From 1881 to 1884 he was president of Saint Mary's College, Kansas, and in 1908 was appointed professor of literature at Saint Ignatius College (now Loyola University), Chicago. He is the author of 'Introduction to English Rhetoric' (1885); 'Oratorical Composition' (1886); 'Logic and Metaphysics' (1892); 'Moral Philosophy' (1896); 'Moral Principles and Medical Practice' (1898); 'The Living Church of the Living God' (1902); 'Systematic Study of the Catholic Religion' (1903); 'Protestantism, How it was Brought About' (1907); 'A Brief History of Philosophy' (1909); 'Who are the Jesuits?' (1911). He contributed to 'The Catholic Encyclopedia,' the *American Ecclesiastical Review,* etc. He died 14 Dec. 1920.

COPPER, a butterfly of the genus *Chrysophanus* of the family *Lycænidæ.* They are small, have the upper side of the wings some tint of copper-red or orange, frequently glossed with purple; the under side of the wings is marked with small spots and lines. The caterpillars are slug-shaped, thickest in the middle and with small heads. The genus is distributed over the temperate regions of both continents, 13 species inhabiting North America.

COPPER, a metallic element occurring abundantly in nature, and widely used in the arts, both in the pure state, and as an essential constituent of many alloys. It has been known from the earliest times, and is frequently mentioned by the ancient writers. Prehistoric weapons, tools and ornaments of copper, as well as domestic implements, remain in profusion to this day; and it has been commonly asserted that copper was known and used before iron, though some authorities consider the evidence of this to be inconclusive. The Romans obtained their best copper from Cyprus, an island in the Mediterranean Sea, and for this reason the metal was known as *Cyprium æs,* or "Cyprian brass," a name that was later contracted to *cuprum* and *cuper.*

Physical Properties.— Copper is red in color, and crystallizes in cubes, octahedra and other forms of the isometric system, twinned crystals being quite common. When in a finely divided condition it has a specific gravity of about 8.36; but the specific gravity of native copper is 8.84, and that of hammered or electrically deposited copper is about 8.95. It melts at about 2000° F., and has a specific heat of about 0.093, and a coefficient of linear expansion of about 0.0000092, per Fahrenheit degree. Its tensile strength varies greatly, according to the physical condition of the metal. The following data are commonly used in engineering practice, as corresponding to the tensile strength in pounds, per square inch of sectional area: Cast copper, 19,000; sheet copper, 30,000; copper bolts, 36,000; copper wire, 60,000. The thermal conductivity of copper, at ordinary temperatures, is about 0.74 times that of silver. The specific electrical resistance of hard-drawn copper is 1,620 ohms, and that of annealed copper is 1,584 ohms. A wire of the metal that is one metre long and one millimeter in diameter has a resistance of 0.0206 ohms if hard drawn, and 0.202 if annealed. These data are for the pure metal, at the temperature of freezing water. The electrical resistance of copper increases by about 0.388 of 1 per cent for each Centigrade degree of rise of temperature. The electrical resistance is also greatly increased by the presence of small percentages of iron, zinc, tin, phosphorus or arsenic, and hence great attention is paid to the purity of the copper that is intended for use in electrical conductors. Copper is very malleable and ductile, and may be drawn into small wire and hammered into exceedingly thin sheets. An alloy consisting of 11 parts of copper and 2 of zinc is even more malleable than copper itself, and may be hammered into foil comparable in appearance with gold-leaf, for which it is used as a substitute in certain kinds of work, under the name of "Dutch metal." Copper becomes very soft and malleable when it is strongly heated and immediately immersed in cold water, its behavior under these circumstances being diametrically opposed to that of steel. It may be forged into any shape, but it will not bear more than a red heat, since it becomes brittle at higher temperatures. It does not oxidize readily under ordinary conditions, but becomes superficially tarnished with a coating of carbonate that resists the subsequent action of the oxygen of the air. Copper often gives poor castings, apparently because the molten metal absorbs gases, and these, when given off again at the moment of solidification, make the casting porous. The castings are said to be much more sound when a small quantity of phosphorus is added to the molten metal — usually in the form of phosphor-copper. The large copper cylinders that are used in calico-printing are cast in molds, and are subsequently hammered under a steam-hammer until the metal is sound, and then turned down in a lathe until the surface is true and free from defects.

Alloys.— Many alloys of copper are used in the arts, chiefly under the name of "brasses" or "bronzes." Originally a brass was defined as an alloy of copper and zinc, while a bronze was defined as an alloy of copper and tin. This convention is still retained in a general way, but the same names are applied also, and very commonly, to numerous ternary alloys, containing copper, zinc and tin, which pass by insensible gradations from a true brass to a true bronze; so that "brass" and "bronze" can no longer be

regarded as very definite terms. Alloys of copper with aluminum are called «bronzes,» even when no tin is present. See ALLOYS; BRASS; BRONZE.

Chemistry.—The chemical symbol for copper is Cu (*cuprum*), and the atomic weight of the metal is 63.1 if H = 1, and 63.6 if O = 16. Performs two distinct series of salts, known respectively as «cuprous» and «cupric» compounds. In the cupric series the metal is a dyad, while in the cuprous series it enters into the ordinary formulae as though it were a monad. (See CHEMISTRY). Structural formulae have been given, however, which indicate that the metal is really a dyad in both cases. The cupric series of salts embraces those compounds that are most familiar in the arts. Cupric oxide (known also as copper monoxide, or black oxide) is formed when metallic copper is heated in the presence of air. It may occur as a brownish-black amorphous powder, or in lustrous monoclinic crystals. Cupric oxide is used in the laboratory for effecting the combustion of organic substances, the oxide being intimately mixed with the body to be oxidized, and the whole raised to a red heat, at which temperature the cupric oxide readily gives up its oxygen to either hydrogen or carbon. Cupric oxide (the formula of which is CuO) is soluble in acids, and yields, with them, salts which crystallize well. If a solution of any of these salts be made alkaline by the addition of a caustic alkali, a light blue precipitate of cupric hydrate, $Cu(OH)_2$ is thrown down. Upon heating to 212° F., this parts with a molecule of water and becomes reduced to the black oxide, CuO. If cupric hydrate be precipitated by adding the calculated quantity of sodium hydrate to a solution of copper sulphate, and the precipitate is mashed and dissolved in ammonium hydrate, a blue solution is obtained, which is sometimes called «cupro-ammonium hydroxin,» and which possesses the singular power of dissolving cellulose (q.v.) without chemical change. When pure cupric oxide is desired, it is most conveniently prepared by heating cupric nitrate to redness. Cupric nitrate is readily prepared by dissolving metallic copper in nitric acid. It crystallizes in large blue prisms, having the composition $Cu(NO_3)_2 + 6H_2O$. Ordinary copper sulphate (cupric sulphate, or «blue vitriol») is manufactured in large quantities by dissolving scales of copper oxide (CuO) in sulphuric acid. It forms large blue triclinic crystals, which have the composition $CuSO_4 + 5H_2O$. The sulphate is used in calico-printings, and in the manufacture of various copper pigments such as Brunswick green and Scheele's green. Cupric chloride, $CuCl_2$, is formed by dissolving cupric oxide in hydrochloric acid, or by acting upon metallic copper by chlorine gas. It is soluble in alcohol or water, and forms acicular crystals having the formula $CuCl_2 + 2H_2O$. Cupric sulphide, CuS, is the familiar black precipitate that is obtained when sulphuretted hydrogen gas is passed through an acid solution of a copper salt. (See CHEMICAL ANALYSIS). Copper carbonate, $CuCO_3$, has not been prepared in the pure state, but a green precipitate having the formula $CuCO_3 + Cu(OH)_2$ is thrown down when carbonate of potassium or of sodium is added to a solution of a copper salt; this precipitate being identical in composition with the mineral malachite. Cuprous oxide, Cu_2O, or red oxide of copper, occurs native in red octahedral crystals, and it may also be prepared artificially by heating a mixture composed of equivalent parts of cupric oxide and finely divided metallic copper, or (more conveniently) by heating a mixture of equal parts of cupric oxide and ammonium carbonate, $(NH_4)_2CO_3$, over a Bunsen burner, until all the ammonia is expelled. It is a crystalline powder of a carmine color, melting at a strong red heat, and is used in glass manufacture for the production of a ruby color. The precipitation of this oxide from certain test-solutions is used as a test for the presence of sugar in urine. (See URINARY ANALYSIS). Cuprous oxide dissolves in various acids with the production of colorless salts, which are unstable, since they readily absorb oxygen and pass into the corresponding cupric salts. The most important cuprous salt is the chloride, which has the formula Cu_2Cl_2, and is formed by heating metallic copper to dull redness in a current of hydrochloric acid gas, or by dissolving a mixture of cupric oxide and metallic copper in hot hydrochloric acid. It is a white crystalline powder, insoluble in water or alcohol, or in dilute nitric or sulphuric acids, but dissolving in ammonia, or in hot hydrochloric acid. Its solution in either of these menstrua possesses the remarkable property of absorbing carbon monoxide gas. Copper may be detected in solution (1) by the formation of the black sulphide when a stream of sulphuretted hydrogen gas is passed through the acidified solution; (2) by the precipitation of the blue hydroxide, which blackens upon heating; (3) by the deep blue color that its salts give upon the addition of ammonia; and (4) by the precipitation of a red film of metallic copper when a clean, bright fragment of iron is immersed in the solution.

Physiological Action.—In medicine, salts of copper are used as astringents and as antiseptics, copper sulphate being the favorite salt. The soluble salts of copper are all exceedingly poisonous, and since the metal is very widely used in the arts, copper poisoning is quite common. In acute poisoning the symptoms are those of an acute gastro-intestinal irritant. These usually develop in from 10 to 20 minutes, though they may be delayed as much as two or three hours. There is nausea and vomiting of bluish material, accompanied by a metallic taste in the mouth, and intense burning in the stomach, with great abdominal tenderness. If all the copper is ejected by the emesis, the patient usually recovers. This is usually the case, but sometimes, when the dose is extremely large, vomiting is ineffectual. In addition to the symptoms already given, intense headache then develops, accompanied by great prostration and cramps, with small, rapid pulse and collapse; death sometimes following in from 4 to 12 hours, but more commonly after two to four days or more.

Ores and Occurrence.— Native copper occurs in nature, and in the Lake Superior district (Michigan), forms the chief ore. Chalcocite (Cu_2S), chalcopyrite ($CuFeS_2$), bornite (Cu_3FeS_3), enargite (Cu_3AsS_4), covellite (CuS), tetrahedrite ($Cu_3Sb_2S_7$), azurite [$2CuCO_3.Cu(OH)_2$], malachite [$CuCO_3.Cu(OH)_2$], chrysacolla ($CuSiO_3.2H_2O$) and cuprite (Cu_2O), are all important ores.

Practically all our important copper deposits

are the result of heated waters related to volcanic activity. Typical contact metamorphic deposits are found in the Clifton-Morenci district of Arizona and in the limestone deposits of Bingham, Utah. Bisbee, Ariz., and Ely, Nev., are also classed with this type. The Butte, Mont., ores are typical vein deposits formed by hot waters. Globe, Bisbee and Clifton-Morenci all show typical replacement deposits in limestone. The Bingham camp in Utah is now noted for its enormous bodies of low grade disseminated ore in porphyry. The Globe, Miami and Ray districts of Arizona contain great disseminated deposits in Pre-Cambrian schists. The Lake Superior ores are chiefly native copper, occurring in the vesicular openings (amygdules) of lava flows, or replacing interbedded layers of conglomerate. As indicated above, one district may show several types of ore deposit. See ORE DEPOSITS.

The greatest copper producing locality in the United States was for many decades the Butte district of Montana. The copper veins are confined to a comparatively small area lying north of Silverbow Creek, about two miles in length and one and one-half miles in width. Several of the mines now producing copper were opened as silver mines, the silver being replaced by copper at the depth of about 150 feet. This locality produced in 1916 349,500,000 pounds of copper, equivalent to 17.42 per cent of the entire output of the country. The output of copper from this district in 1929 totaled 297,000,000 pounds as compared with the 1925 production of 268,725,000 pounds and the 1924 production of 249,152,062 pounds. The ore most common in this region, and which has supplied 75 per cent of the entire output, is chalcocite, or copper glance—a sulphide, carrying 79.8 per cent of metallic copper. This ore was originally pyrite, and has been altered by hot descending waters containing copper sulphate. About 20 per cent of the Butte copper production has been from enargite, a sulpharsenate of copper, carrying 48.67 per cent of the metal. About 4 per cent has been recovered from bornite, an altered chalcocite, carrying 63.3 per cent of copper. The remainder has been gained from covellite, chalcopyrite and tetrahedrite.

Three other localities in the United States are eminent as producers of copper; the Keweenaw (Lake Superior) district of Michigan, the Bisbee district of Arizona and the Bingham Canyon district of Utah. Michigan began producing in 1845, and in 1929 produced 185,301,000 pounds, practically all recovered as native copper. The Bisbee district began production in 1880. Other districts have contributed in Arizona since the first mine within its borders was opened in 1873. In 1925 Arizona produced 713,355,129 pounds and 829,207,000 pounds in 1929. The ores of Arizona are virtually the same as in Montana, the upper earth section being barren through having its copper leached away for a depth of about 250 feet and deposited in the veins of the 100-foot zone below. Chalcocite is the principal ore, altered in places. Utah produced 325,965,000 pounds of copper in 1929.

Smelting and Refining.—Mining the ore is but the preliminary step in the production of commercial copper. The crude ores must be smelted and the smelted product refined. The first treatment the ore receives after being raised is concentration. This is a mechanical treatment with the object of eliminating as much as possible of the gangue or non-ore-bearing rock accompanying the ore. It makes use of the methods of hand-picking, wet and dry jigging tables and hydraulic separation. The ore then goes to the smelter.

The particular smelting process employed depends on the chemical constitution of the ore: that is, whether it is a sulphide, an oxide or native copper. With the sulphide ore the first operation is roasting, in order to oxidize the sulphur and iron present, and to volatilize the arsenic, bismuth and antimony. The roasted ore is then reduced in a blast furnace with anthracite coal, the product of this state being known as «matte.» This is again roasted and again passed through the blast furnace, the product being the impure copper known as «black copper.» Oxide ore is reduced by mixing it with sulphide and then smelting it for matte, as explained above. Native copper ore is smelted with anthracite and coke in a reverberatory furnace, with or without the addition of limestone flux. The product is crude metallic copper, which is often tapped directly into the refining furnace.

The metallic copper of various forms as it comes from the reducing furnaces contains as impurities some if not all of the following named minerals: iron, nickel, cobalt, lead, zinc, tin, arsenic, antimony, bismuth, sulphur, selenium and tellurium, besides a percentage of silver and gold. The object of the refining process is to remove to the utmost practicable limit all of these substances, and to turn out the metallic copper at least 99.8 per cent pure. The process of fire-refining is essentially an oxidizing process. It is, however, conducted at a degree of heat so high that such metallic impurities as arsenic, antimony and bismuth are volatilized. The other metals present are oxidized into dross and removed with the slag. The cuprous oxide (Cu_2O) held in solution in the metal, the only oxide of copper which is stable at the melting point of copper, is gradually reduced until only about one-half of 1 per cent remains, and this is left in the metal to make certain that no other metallic impurities are present except in the form of harmless oxides. The furnace used in fire-refining is of the reverberatory type. The more impure the metal the longer the treatment and the smaller the quantity which can be worked at one time. The «charge» of solid copper, in the form of cakes, is placed in the furnace basin by hand or by mechanical appliances, and the first or melting fire is set in the fire-box. If the copper is relatively pure it melts quickly; if impure «black» copper, it is much slower and may be hastened with an air blast. When the melting is complete the fire is drawn and a new, oxidizing fire built. As the slag forms it is constantly skimmed away and the clear metal exposed. Cuprous oxide is formed on the clear surface and is dissolved in the molten metal. The metallic impurities which have a stronger affinity for oxygen than has copper take up oxygen from the cuprous oxide and rise to the surface as slag. This operation is forwarded by forcing air into the molten metal through iron pipes dipping well down below the surface. These pipes melt off in the great heat, but the iron is oxidized and rises to form part of the slag.

When the slag ceases to form, the melted copper retains about 6 per cent of cuprous oxide in solution. This proportion of cuprous oxide is reduced by the process of "poling," which consists of forcing poles of green timber, butt end first, into the mass of melted copper, and feeding them in as they burn away. A state of ebullition is excited by the vapors arising from the scorching wood: the carbonic oxide and hydrogen set free seize upon the oxygen of the cuprous oxide and the charcoal aids in the reduction. This operation is continued until a microscopic examination determines that the cuprous oxide is reduced to the correct proportion — from .5 to .7 per cent. If the poling is carried too far the other impurities give up their oxygen and resume their metallic state, and the entire mass of the copper has to be reoxidized to the 6 per cent content, and the poling done over again. When the copper has reached the proper constitution it is cast into ingots, ingot-bars, wire-bars or cakes.

The electrolytic method of refining copper is generally preferred in the United States, and nearly three-fourths of the country's product is thus refined. This process is essentially electroplating. The anodes are of cast copper, about three feet square and one inch thick and weighing 475 pounds each. The cathodes are of pure electro-deposited copper, a little longer and wider than the anodes, and about one-sixteenth of an inch thick. The anodes are placed in the tank at from three to five inches apart; the longer distance for the more impure metal. A cathode is hung between each of two anodes and one at each end of the tank. The tanks are built of timber and lined with lead. They are two inches wider than the cathodes, allowing an inch of free electrolyte at each side. The tanks are usually about 10 feet long and hold from 20 to 30 pairs of anodes and cathodes, connected usually in multiple. Some few of the largest works, however, connect them in series. The electrolyte is a solution of copper sulphate in the proportion of 12 per cent, and acidulated with about 9 per cent of sulphuric acid. The copper content is held up to at least 3 per cent to prevent plating with arsenic where it is presented in the anode. The free sulphuric acid in the bath is limited to 12 per cent to avoid decomposition. The temperature of the electrolyte is held between 105° and 140° F. by means of steam coils. A continuous circulation of the electrolyte is necessary to prevent irregular deposition. The current ranges from 12 to 34 amperes per square foot of anode. The lower figures are adopted where arsenic is present. The voltage varies in different plants from 60 to 180. The time required to deposit the pure metal from the anode is about 20 days.

In 1916 there were active in the United States 13 refineries, nine of which employed the electrolytic method and five the furnace process on Lake Superior copper — one employing both methods—with total output of 2,259,387,000 pounds. In 1928 refined copper production totaled 3,560,000,000 pounds, divided as follows: new or primary, 2,487,600,000 pounds, and old or re-refined copper, 1,072,800,000 pounds. The new copper consisted of 1,791,800,000 pounds of domestic and 695,800,000 pounds of foreign copper. Of the new copper there were 2,300,900,000 pounds of electrolytic, 179,100,000 of lake, and 7,600,000 of casting copper. Besides the new copper produced there were 84,700,000 pounds of refined imported. The exports of refined copper amounted to 949,474,000 pounds of the value of $140,340,000.

Secondary Copper is the name given to the copper recovered by smelters and refineries from scrap metals, sweepings, skimmings and dross, as distinguished from the primary copper derived directly from ores. The production of secondary copper in the United States in 1916 was unprecedented up to that time, very large quantities of scrap from rolling mills and munition works finding their way to the secondary smelters. The record for the year shows copper and copper in alloys (exclusive of brass), and brass containing about 70 per cent of copper to a total of 350,000 tons, valued at $196,320,000. In 1928 the grand total amounted to 536,400 tons.

Commercial Copper.— In the American markets copper appears in three grades: electrolytic, Lake and casting copper. Both electrolytic and Lake grades test at least 99.8 pure. Electrolytic copper has a slightly higher degree of conductivity than Lake copper and greater endurance in bending and twisting tests, and is therefore preferred for electrical work. Casting copper is a fire-refined blister copper, testing sometimes as low as 98.5 per cent pure. It is unsuitable for electrical purposes or for making brass wire and sheet brass, but is available for making copper or brass castings. The principal forms in which copper is marketed are ingots about 3 by 3 by 9 inches, weighing about 17 pounds; ingot-bars, about 3 by 3 by 27 inches, weighing about 50 pounds; wire-bars, about 3½ by 3½ by 33 and up to 60 inches, and weighing from 85 to 250 pounds; and cakes, in round or square forms, ranging in diameter from 8 to 39 inches, and 14 by 17 inches up to 42 inches square, and from 1½ to 8 inches in thickness. About one-third of the entire copper product of the country is used in making wire and electrical supplies and one-fourth in making brass.

Production.— The world's smelter production of copper for the year 1916 amounted to 3,106,995,660 pounds (estimated in part), an increase of more than 31 per cent over the production of 1915, and almost exactly double the production of 1906. Of the grand total, the United States smelters produced 1,927,850,548 pounds (62 per cent); Japan, 179,189,888 pounds (5.8 per cent); Chile, 157,474,578 pounds (5.1 per cent); Canada, 119,770,814 pounds (3.8 per cent); Mexico, 111,625,577 pounds (3.6 per cent); Spain and Portugal, 110,230,000 pounds (3.6 per cent).

In the United States the mine production in 1930 was 42,428,571 tons of copper ore, containing 1,485,000,000 pounds of metallic copper— an average of nearly 35 pounds per ton of ore. Not all of this was recovered (in 1930) by the smelters, and this accounts for the variance with the figures given above for the United States under the world's production. In about 1,000 mines copper was the principal product, and these mines produced a total of 1,450,000,000 pounds. In over 800 other mines copper was recovered as a by-product to the amount of 35,000,000 pounds.

Among the States, Arizona maintained first rank even with the reduced output of 564,500,000 pounds, more than 35 per cent of the output of the whole country, and a decrease of

45 per cent from her record yield of 1929. Montana held second rank, with 198,200,000 pounds. Michigan was third with 178,442,000 pounds; Utah fourth, with 178,278,000 pounds; Alaska fifth, with 89,000,000 pounds, and Nevada sixth, with 85,189,000 pounds. The year 1916 held the record in smelter output from domestic ore, also for domestic refined output, until 1929.

The world's mine production of copper in 1929 was 1,908,845 metric tons, of which the United States produced 931,103,000 tons, or 48.8 per cent. Chile, now the second largest producer of copper, had an output in 1929 of 316,037,000 tons; Canada, 109,908,000 tons; the Belgian Congo, 89,156,000 tons (1927); Mexico, 78,708,000 tons; and Japan, 74,645,000 tons. In the United States there were mined in 1928 a total of 62,097,000 short tons of copper ore, with an average yield of 1.41 per cent of copper. The smelter output from the domestic ores was 1,825,900,000 pounds, valued at $262,930,000, and was increased to 2,002,863,000 pounds in 1929 with a value of $352,504,000. The production of new domestic copper from the refineries in 1936 amounted to 1,222,819,396 pounds, while the new foreign copper from the refineries amounted to 353,817,802 pounds. Exports in 1936 were 525,000,000 pounds, and imports 380,677,700 pounds.

COPPER, Discovery and Development. Copper in a metallic form occurs, either alone or in connection with chemical combinations of the same metal, in many parts of the earth, notably in Peru, Chile and neighboring countries, in Alaska, in parts of South Australia and more sparingly in Siberia, in Cornwall, in Germany, in several of the United States and elsewhere. In few localities has it been found in quantities as large, or under circumstances as favorable for large mining operations, as in the Lake Superior region. The attention of the early navigators to America, next to the finding of a northwest passage to Asia, was directed to the natural resources of the New World, and especially to its deposits of valuable minerals.

Of early references to copper in North America that of Verrazzano in 1524 is among the first. He saw, on the coast of New England, beadstones of that metal in the ears of the natives. In 1535 Jacques Cartier, on his second voyage to the Saint Lawrence River, was told by the Indians that native copper — *cuyvre rouge* — by them called "caignetdaze," came from the Northwest, from the region known to them as Saguenay, and they gave to their chief, Donnacona, when he sailed for France with Cartier, a large knife of that metal.

In 1610, Champlain, on one of his excursions up the Saint Lawrence, is said to have been given a piece of copper a foot long, that was reported to have come from the bank of a river near a great lake. "The Indians asserted that it was gathered in lumps, and, after having melted it, they spread it in sheets, smoothing it with stones."

On Champlain's map of 1632 we find in a lake northwest of Lake Huron an island marked "where there is a mine of copper." This might have been either Michipicoten Island or Isle Royale.

Sagard, who published his 'History of Canada' in 1636, wrote that Bruslé, one of Champlain's interpreters, showed him a "lingot" of copper which had come from a mine 80 or 100 leagues from the Hurons.

In 1660 Pierre Esprit Radisson, probably the first white man to explore the shores of Lake Superior, was led by an Indian companion to a place near the banks of a small stream that flows into the lake east of the Pictured Rocks, where he saw "many pieces of copper uncovered," and was told that a mountain near by was "nothing else." As this spot is outside of the area of the copper-bearing rocks the copper was either "float" or had been hidden there by the Indians. Radisson was also told that an island at the end of Keweenaw Point (Manitou Island?) was "all of copper."

In the Jesuit 'Relations' of 1659–60 it is said that an Indian reported copper from Lake Superior in pieces as large as one's fist. In the 'Relations' of 1666–68 Father Allouez reported pieces of true red copper from an island in Lake Superior, which, according to his description, was probably Isle Royale.

In the 'Relations' of 1669–71 Father Dablon reports red copper from the Ontonagon River, concerning which he says opinions differed as to where it was actually found; and also from the end of Keweenaw Point — the latter place being an islet "which appears to be six feet square, and is said to be all copper." This sounds like the report made to Radisson, except that no size was given to Radisson's islands, whose distance from the mainland corresponds with that of Manitou Island. The Jesuit Fathers were also assured by the Indians that in the interior to the south of Lake Superior "mines" of copper were found in different places. This report might possibly have some significance in connection with the so-called prehistoric miners, if the term *mine* had been used by the Jesuit Fathers with the meaning usually attached to it to-day, as something *in esse* rather than *in posse* — a rock formation carrying a workable deposit of mineral, rather than an isolated mass, one that had been removed to a distance from the parent bed. We know that the term was used loosely by later writers, even in the first half of the 19th century. H. R. Schoolcraft in 1821, when referring to the celebrated copper mass on the Ontonagon River, speaks of it as a mine.

With the exception of the "islet" referred to by Dablon which was possibly a piece of mass copper projecting out of the water at a shallow spot near the shore, all of the copper found as late even as the latter half of the 18th century appears to have been "float," that is, masses of smaller or larger size that had been transported from their original beds, generally by glacial action. Indeed it was this fact that probably explains the statement of Capt. Jonathan Carver in 1778 that the copper itself costs nothing.

The area of «float» copper appears to have extended much beyond the territory immediately tributary to Lake Superior, for in 1700 Le Sueur found pieces of it near the mouth of the Chippewa River and another about four leagues above the mouth of the Saint Croix River, in Wisconsin. In later years similar finds have been reported as far south as Indiana and Illinois. But while Lake Superior was supposed to be the source of this copper we do not find any evidence that any white man — except always Father Hennepin — had even seen anything that could be called a copper mine (sic), as early as the time of Charlevoix. The latter in his history of New France, published in 1744, says «It is certain that there has been discovered in several places a considerable quantity of this metal, without even being obliged to dig much.» It is true that La Hontan early in the 18th century speaks of copper mines on Lake Superior, but he does not claim, like Hennepin, to have seen them. We also find many references to copper «mines» in the interior as reported by the Indians, who usually showed great reluctance to disclose their whereabouts to the white man.

Thus far the pieces of native copper found on Lake Superior were gathered on the edges of the islands and on the borders of the lake along the highways of navigation by canoe. It was not until 1765 that Alexander Henry, attracted by Indian reports of a large mass of copper, the one referred to by Dablon, visited the Ontonagon River and went up stream several miles above the junction of the east and west branches. He found, on a clay bank, at or near the edge of the stream, the copper mass, with some rock adhering to it through which ran small veins of copper. In 1771, revisiting the same place, he noticed also much copper bedded in stone, and left a party of miners there, «to make a trial on the hill, till we were better able to go to work on the solid rock.» They dug 40 feet into the clay bank and found frequent masses of copper. All went well during the winter, but when spring came, the clay thawed and caved in, and the party left. In recording the above facts, Henry added that «The copper ores of Lake Superior can never be profitably sought for but for local consumption. The country must be cultivated, and peopled, before they can deserve notice.» In a footnote to the above, having in mind the more roseate view then recently expressed by Alexander Mackenzie and earlier by Captain Carver, he adds, «The copper mines of Lake Superior have been more than once represented to the world in colors capable of deceiving fresh adventurers: and the statement in the text will not have been uselessly made, if it should at any time serve as a beacon to the unwary.» The fame of Henry's operations was probably spread abroad at the time, although his book was not published until 1809.

Henry's visit to the Ontonagon River marks the culmination of the efforts of two and a half centuries of search for the original source of the Lake Superior native copper — its location in the rocks of volcanic origin that almost surround that inland sea. It also marks the beginning of an industry that in spite of Henry's warning has grown to be one of the most important of the Northwest. Possibly the troubles that distracted the country during two wars, and the boundary disputes in the region of the Great Lakes, rather than the adverse sentiment caused by Alexander Henry's failure, kept back the development of the copper district of Michigan, but the spirit of expansion which during the administration of Jefferson found expression in the expeditions of Lewis and Clark and of Pike later found an echo in Gov. Lewis Cass, at whose initiative and under whose personal leadership an expedition to the Northwest was effected in 1820, one of the objects of which was to investigate the copper «mines» of Lake Superior. Henry R. Schoolcraft accompanied this expedition as mineralogist. They visited the Ontonagon copper mass, which Schoolcraft recognized as having been removed from its original bed of «serpentine» rock; from which circumstance he inferred that there must be extensive «mines» in the vicinity.

In 1832 Schoolcraft, this time with Dr. Douglas Houghton as geologist to the party, again visited the Ontonagon River and the famous copper mass. On the way thither Dr. Houghton found copper embedded in the trap rocks on the western side of Keweenaw Point, and expressed the opinion that the «trap rock formation was the original source of the masses of copper,» and that copper would probably not be found in that region in any other rock than trap, which Dr. Houghton at that time had seen only on Keweenaw Point.

During 1832 and 1833 Dr. Houghton visited the south shore of Lake Superior three times. Five years later he was appointed State geologist of Michigan and before his death, in 1845, had carefully examined the copper-bearing formations, had ascertained their altitude and extent, had located a number of copper veins and had given to the world enough information to attract at once a large body of prospectors. The interest thus stimulated in the Michigan copper district soon led to the opening of some of its most famous mines. The success of this new industry, as predicted by Captain Carver, was soon assured by the building of the canal at Sault Sainte Marie, which afforded the products of upper Michigan cheap transportation from the wilderness to market.

Geology.— The «trap» rocks that constitute the greater part of the Lake Superior copper-bearing formations are a series of old lava flows. All around the western end of the lake through Michigan, Wisconsin and Minnesota, the trap beds extend for several miles in width, striking nearly parallel with the general trend of the shore line, and dipping always toward the lake, the dip being usually flatter near the shore than it is further back. Associated with these trap beds occur beds of reddish conglomerate or sandstone at different intervals, composed of the débris of the traps and associated more acid rocks.

On the extrusion and flow of lava which has been under pressure, the pent-up gases in it expand near the surface of the flow like the bubbles in a glass of champagne, and as the surface of the flow rapidly congeals, each gas bubble forms a cavity or amygdule. In the scoriaceous or amygdaloidal portions of the lava beds, which are thus characteristic of the upper surface of the bed, though sometimes found at the bottom — also in cavities caused by chemical changes or by fractures, and occasionally in the conglomerates — are frequently found the

deposits of native copper that characterize these formations. At different angles to the strike of these beds fissure veins of later age are found, several of which, notably the Cliff, Phœnix and Central, proved also to be rich in copper, which in the Cliff mine carried with it a large amount of silver. The copper occurs either in minute flakes, or in more compact bodies from the size of a pin head or less to masses of 500 tons or more in weight, of shapes rounded like a boulder or branching irregularly through the parent rock-mass. Large masses seldom occur in the conglomerates, but in these beds individual boulders are often found entirely replaced by copper. In the early days of mining here it was the fissure veins that were sought and worked almost exclusively. They produced a large amount of mass in a small area of ground, and this could be made marketable without the expense of treatment in a stamp mill. By the time the fissure veins were beginning to show signs of exhaustion the amygdaloid deposits came more into notice and soon proved that while they were less rich than the veins, volume for volume, they were much more extensive, and, with the progress in mining methods, would probably prove profitable if worked on a large scale. The substitution of air drills for hand drills and of high explosives for black powder helped to confirm this promise. Meanwhile the discovery of the Calumet conglomerate with its wealth of mineral had been made. As work on the fissure veins was gradually being abandoned, the mines were in popular parlance grouped into two classes — amygdaloids and conglomerates. To-day, however, it is apparent that all so-called amygdaloid copper deposits are not properly so named and a further division is possible. Throughout the formations, especially along the upper surfaces of conglomerate beds, planes of weakness have existed along which there has been more or less movement of the overlying formations. These planes of weakness not infrequently coincide with the amygdaloidal upper portions of the trap beds, both in strike and dip, and shearing movements along them have fractured the rock to so great an extent as to form a veritable breccia, in which copper was later deposited in workable quantities. Indeed the copper often occupies the interstices in these breccia beds, while the amygdules of the rock composing the breccia are entirely filled with minerals other than copper. In a case of this kind the term «amygdaloid» deposit, if not confusing, is at least inexact.

Exploration.— The greater part of the area underlain by the copper-bearing formations of Lake Superior rise to an elevation of from 400 to 700 feet above the lake. Several ridges stand out above this general plateau whose summits show naked rock, and even in the lower ground there are some exposures of rock in place, but over a large area there is a heavy covering of «drift» — sand, gravel and boulders — which completely conceals the rock surface and renders difficult a successful search for mineral. When mining operations began on Keweenaw Point the attention of the early prospectors was attracted by grooved stone hammers, some of which weighed as much as 30 pounds, generally found on the ridges, in or by the side of shallow excavations that showed copper embedded in the rock. These traces of crude mining by a former generation evidently served as a guide to the early white miners in locating the most prominent deposits. The ridges naturally consist of the hardest rock — the massive trap beds that have resisted erosion better than the softer amygdaloids. By following these ridges the early prospectors located the fissure veins, and with them some quasi fissure veins that ran parallel with the formation and contained large masses of copper, rough prongs of which projected above the rock surface. A «conformable vein» or an amygdaloid deposit thus located would be followed for miles, until perhaps it disappeared beneath a covering of drift. Sometimes a large block of cupriferous rock would be found, whose angularity indicated its probable nearness to the parent bed. Surmising the direction of the glacial movement the prospector would dig a series of trenches or *costeans* at right angles to the strike of the formation, on the side whence the glacial movement was supposed to have come. But here again in early days the fact was not recognized that Keweenaw Point had been the scene of glacial movements from at least two directions, and thus in one well-known instance explorations were vainly made in the wrong direction from the blocks of rich float-rock.

With the progress of geological investigation it was realized that the conglomerates interbedded with the traps and representing old sea beaches were more or less continuous around the ancient basin. Their character, it is true, does not remain constant from point to point, for this depends in a great measure upon the rocks that lay behind them during the process of their formation. They furnished reliable aid to correlation, however, and could be followed and recognized for long distances even across drift-covered areas. The lava beds, on the other hand, from their broad general similarity, usually were not safe guides. In some cases, however, even these could be identified over long distances by some marked peculiarity. If a workable copper deposit was known to exist near one of these conglomerates or near a recognizable trap bed, the latter was traced out and a pit or trench was then dug at a known distance from it equivalent to the distance of that bed from the copper-bearing bed at the place where the latter was last seen, allowance being made for ascertainable changes in the dip of the formation between the two places. In this way the Baltic lode of the Champion Mine was located about three miles from the Baltic Mine, although in the intervening distance the strike of the formation had changed 34 degrees. By taking the great Greenstone ridge in Keweenaw County as a guide the position of the northward extension of the Kearsarge amygdaloid bed was in a similar manner approximately ascertained about six miles from the nearest point at which it had been previously opened. While trenching was in progress to uncover this bed, the recognition of an isolated outcrop of its footwall — a very characteristic rock — pointed more exactly to the location of the amygdaloid. Exact calculations are not always possible, for the dip of the beds from younger to older may change — commonly does change — and can seldom be determined for any one place, in advance of mining. The diamond drill is often an important aid in cases

like the above, where the thickness of the drift-covering makes trenching impossible or too expensive.

Development.— A mere deposit of mineral or an isolated mass is not necessarily synonymous with a "mine," as previously remarked. As now frequently understood, a "mine" is a deposit sufficiently exploited to afford reasonable hopes that it can be worked at a profit. To ascertain whether a native deposit of copper in Michigan will pay requires a good deal of time and the expenditure of a large amount of money. Shafts must be sunk, generally, in the lode to test the latter continually in depth, and drifts must be driven from the surface, to show the lateral extent of the deposit, its uniformity and richness. If the rock mined carries from 1 to 2 per cent of fine copper, or from 20 to 40 pounds per ton, and the lode is 10 feet or more wide, the management knows that by mining on a large scale the costs can be brought down to a paying basis with copper at about 12 cents a pound. Some mines with wide deposits can make a handsome profit at the last named price. In the exploratory stages of a mine these factors must be ascertained before a permanent and economical plant can safely be installed. By neglecting this precaution several notable failures have been made and expensive plants erected only to be sold out later at a loss. In Michigan the copper deposits usually extend to great depths, some of the older mines being a mile deep vertically. Powerful hoisting engines and other machinery in proportion are ultimately necessary for this work. The permanent shaft can be sunk in the footwall so as to enable the removal of the maximum of copper-rock without endangering the shaft. The percentage of copper-rock that can be safely and cheaply mined often has an important bearing on the method of mining that is to be adopted. The shafts where possible follow the dip of the lode, thus avoiding the unnecessary mining of barren ground to reach the lode from the shaft, as would be the case if the latter were vertical. Shafts are now placed a thousand feet or more apart. The drifts from the shafts are driven along the lode from 85 to 150 feet apart, measured on the dip of the lode. From these shafts as starting points all of the lode matter possible is broken down from above by "stoping," as far as the next higher level, by various methods; sorted where possible, and the barren portions left in the mine or returned to it from the surface, as "filling" to support the hanging wall. The amount thus discarded will vary according to the nature of the deposit, up to 40 per cent of the total rock mined. In some cases the copper is so evenly disseminated through the rock that sorting is impracticable and all of the rock goes to the mill. The copper rock from the stopes is trammed by hand, or where the shafts are far enough apart, by mechanical power, to the nearest shaft, hoisted in the cars in a cage, or in skips of a capacity of two to eight tons, dumped on the surface in the upper part of the rock-house and here sometimes sorted again, or all of it delivered to breakers, by which it is crushed to small sizes; it is then transported to the stamp mill. The larger masses of copper mixed with rock are placed under a heavy hammer by which the rock is beaten off; the masses are then sent directly to the smelter. After going through the breakers the fine rock falls into large bins and is drawn off into railroad cars for transportation. To save expenses as many operations as possible are performed by gravity. A constant effort also is made to introduce labor saving mechanical devices both underground and on the surface.

Stamping.— The crushed copper-rock from the mine in centre-dump railroad cars is taken to the stamp mill, which sooner or later forms part of the equipment of every permanent mining company. Nature seldom furnishes a place that combines all the essentials of a good stamp mill site. The principal of these are an abundant water supply, dumping-room for the waste products, sufficient elevation for handling the material by gravity through the different stages of the stamping process, accessibility by railroad and storage room for fuel. The absence of any one of these essentials adds materially to the cost of construction or to that of subsequent operation. Where possible, the side of a hill is selected near a body of water. A stream that will supply three and a half million gallons a day throughout the year is large enough for a one-head mill with a capacity to stamp from 500 to 700 tons of melaphyre or 300 tons of conglomerate in 24 hours. If the stream can be dammed at an elevation sufficient to deliver its water by gravity at the mill about 40 feet above the point where the waste launders leave the latter, its water is utilized in that way. A dam built on a stream near the shore of Lake Superior, to serve two mills that have a daily stamping capacity of about 4,000 tons, cost about $250,000. To pump water from Lake Superior for a mill of nearly the same capacity costs between one and one and a half cents per ton of rock stamped, to which must be added interest and maintenance charges on a pumping plant that would cost nearly $100,000. To obtain water from Lake Superior requires a tunnel under the lake or a large pipe leading from the shore to a crib far enough out in the lake to avoid being choked by stamp-sand and other obstructions. This distance is usually about 1,000 feet.

Where the stamp mill cannot be built low enough to enable the rock cars to run from grade into the space above the rock bins, the cars must be hauled up, one by one, by special haulage mechanism. Where the mill is built with the main lower floor but slightly elevated above the level of the dumping ground, the stamp-sand may eventually have to be carried long distances in launders and sometimes must also be lifted to the necessary height by immense sand wheels. Where mills have been built on the exposed shores of Lake Superior the waste sands are removed from time to time by storms, but if built on bays or sheltered places, the heaping up of the sand is likely to give trouble unless the waste launders from the mill are sufficiently elevated above lake level.

The function of the stamp mill is to crush the rock fine enough to be able to separate it from the copper and to recover a maximum amount of the latter. The copper rock from the mine is dumped from the cars into the storage bin at the back of the mill, which is of sufficient capacity to provide against slight delays incident to transportation. From the bottom of the bin the rock runs over a feed

pan into the mortar of the steam stamp, into which also a stream of water is constantly flowing. Here the rock is crushed to a size small enough to be splashed by the downward action of the stamp-shoe through screens around the mortar. The larger lumps of copper are withdrawn from the bottom of the mortar through a tube against the force of a small stream of water which prevents the lighter material from discharging with them. The principle of the so-called hydraulic discharge is utilized in some form at several stages of the stamp mill process. The particles of rock and copper that pass through the screen around the mortar then go through a cylindrical revolving screen or "trommel," the oversize from which under a practice that is now going out of use is carried back to the stamp, or, under better practice, passes directly to a set of rolls that crushes it to a smaller size, thus liberating the included copper and increasing by so much the capacity of the stamp. The entire product from the screens and from the rolls then passes through launders to the classifiers and from these the coarser part of it goes to the jigs. In some cases there is placed under the launders near the stamp-head a box into which by applying the principle of hydraulic discharge, the larger particles of copper fall, the smaller particles of copper and nearly all of the rock passing on to the classifiers. A classifier is a part of the launder system, or a long box through which flows the stream of water from the heads, mixed with finely crushed rock and copper particles; in the bottom of the classifier at stated intervals are openings through which particles of copper and rock drop against a head of water at each opening that can be regulated so as to permit particles of different weight to fall out at the different openings, the heaviest through the first opening, the lightest through the last. On the jigs successively smaller particles of copper are caught on screens of from 10 to 16 mesh, through which gradually sift the very fine copper particles; above the copper caught on the screens accumulate particles of rock which include copper called "middlings." The larger particles of waste rock are carried off gradually at the surface by the jigging motion and by the flow of the water, to the waste launder. The middlings are taken off automatically through an air discharge in front of the jigs and are ground in a Chilian mill, whence they pass to the slime tanks. The fine material passing through the jig sieves goes directly to concentrating tables. The finest particles of rock and of copper that flow through the classifiers from the heads go from these to the settling tanks, where the fine particles of copper with a certain amount of rock material settle gradually to the bottom, and the overflow from the top of the tanks goes to the waste launders. The settlings are then treated on tables provided with elevated strips or "riffles" and by a quick repeated jerky motion in the direction of their length the heavier particles of the pulp, namely, the copper, are gradually separated from the rock matter and collected at the end of the table in tanks or barrels. Middlings or material containing a good deal of rock and some copper from along the irregular line of demarcation between copper and rock are collected and retreated in the same way.

Smelting.— The product of the mine that goes directly to the smelter is in the form of masses, often several tons in weight. This "mass" copper with the product of the stamp mill constitutes what is called "mineral." Large pieces of rock crushed in the breakers at the mine frequently contain small masses which are collected from the rock as the latter goes into the stamp-heads and shipped to the smelter in barrels. This product is called "barrel work." Some pieces of copper as large as one's fist unavoidably get into the stamp-heads and these are taken out through the hydraulic discharges as described above and are shipped as "headings." The finer copper mixed with more or less rock is collected in different grades, the number of these being sometimes as many as six, but in modern practice being reduced to as few as two. The smallest of these grades are called "fines" and "slimes," of which many particles are often minute and light enough to float on a moderate current of water, and hence are difficult to save.

The impurities found with the product of the stamp mill are principally the "vein" rock, from which, owing to the intimate mixture of the copper and rock, the separation of the former has been incomplete, and incidental impurities, such as iron, sulphur, arsenic, with traces of nickel and of some of the rarer elements. The function of the smelter is to remove the impurities and to leave the copper in a condition best fitted for the different uses to which it is to be put. These are principally: (1) For electrical purposes, as wire, where great conductivity is required; (2) for rolling into plates, where great tensile strength may be desired; and (3) for mixing with other metals to form alloys. The forms in which it leaves the smelter are indicative of these uses. They are respectively bars, cakes and ingots. When it is known that .07 of 1 per cent of arsenic in copper will reduce the conductivity of the latter to 75, and that arsenic is almost always present in copper ores, and to some extent also in native copper, the necessity of careful refining will be realized. Copper derived from copper ores generally contains enough impurities to render it unfit for electrical purposes unless it is refined electrolytically. For this purpose it is cast into plates called anodes. In the Lake Superior region the copper derived from the higher or younger formations of the copper-bearing series has generally been found to be pure enough on leaving the smelter to be used for wire (99.9 per cent fine and upwards), but the copper from the lower or older beds usually carries enough arsenic to render such a use impossible without further refinement. This copper, on the other hand, with the proper percentage of arsenic, is tougher and more desirable for some uses than the purer grade.

The mineral is treated first in a melting or reverberatory furnace, the flame passing from the fire-box over the copper under a low arched roof with a stream of air brought in from below. This is an oxidizing process and the slag that separates from the copper and is drawn off from the surface of the latter contains from 8 to 14 per cent of the metal, largely in the form of oxides, mixed with a large amount of the impurities. After the removal of the slag, charcoal is thrown on top of the melted copper and the liquid mass of the latter is agitated by

the insertion of green poles of hardwood ("poling"), the ignition of which and of the charcoal produces the carbon that takes up the oxygen in the copper, thus changing the action of the furnace from an oxidizing to a reducing process. This is often preceded by blowing a charge of air through the molten copper. By dipping small buttons of the metal in a trial ladle from time to time, if the copper sets with a level surface the process of "poling" is complete. If the reduction is overdone, the charge must be reoxidized and again reduced. Thereupon the copper is ladled or run out into moulds. The tendency of modern practice has been to increase the size of the melting furnace contingent upon the ability to keep the heat throughout of an even temperature. Some modern furnaces can take a charge of 100 tons at a heat. It has also been found advantageous instead of doing the refining in these large melting furnaces to run the copper from them into special refining furnaces. The fuel used in the melting furnace is soft coal.

The slag derived from the reverberatory furnace is broken up and eventually taken to a blast furnace, otherwise called a cupola, where the action is reducing, and here the slag is remelted. This process is substantially the same as the process in the reverberatory furnace except that the copper being mixed with a large amount of slag, other substances such as limestone, iron or silica are added to form a proper mixture for fusing and for the proper separation of the copper. The relative amounts of the several materials are ascertained in advance by analysis. All of the ingredients are mixed with anthracite coal, with or without coke, and to stimulate ignition a cold blast of air under compression is driven upwards through the mass. The copper falls out and is drawn off at the bottom of the furnace, containing even then a larger amount of impurities than the product of the first process; this copper should be refined separately. In practice the slag-copper is poured into ingots or ingot-bars, but never into wire bars. It is sometimes specially branded.

The slag that is finally rejected contains about .7 of 1 per cent of copper and is usually discharged into a stream of water which granulates it and carries it away in launders.

LUCIUS L. HUBBARD,
General Manager of Champion Copper Company, Painesdale, Mich.

COPPER, Refining of. See ELECTRO-CHEMICAL INDUSTRIES.

COPPER AND BRASS INDUSTRY. The Naugatuck River has its sources in the hills of northwestern Connecticut and flows southward about 40 miles to its junction with the Housatonic River at Derby, taking its course through a narrow, winding valley. From Torrington, at the head of the valley, to Derby there is a fall of about 600 feet, and wherever the valley broadens to give room for a village or a city there are water privileges, and the power is utilized for manufacturing purposes.

In this narrow valley, which contains a large population, evidence of thrift and prosperity is everywhere seen in the neat, comfortable homes of the workingmen and the fine houses of their employers. This is the seat of the brass-rolling industry of America. Many large corporations are here directly engaged in this business, producing about three-fourths of the total quantity of rolled brass manufactured in the United States, giving direct employment to 25,000 persons and indirectly to many thousands more. About one-half the total quantity of copper consumed in the rolling and wire mills of the United States is conveyed annually to the Naugatuck Valley for use in these manufacturing establishments.

Here were found the men of foresight, energy and activity who could originate great enterprises and carry them to completion. They began the brass-rolling industry 70 years ago. Its development and progress with the growth of the country are due to the energy and ability of those who have conducted the business and furnished the necessary capital for its enlargement. The causes that have led to the concentration of this industry in the Naugatuck Valley are more complex. The cheap power afforded by the water privileges in the valley undoubtedly led to the establishment there of the first rolling-mills, which, as they increased in size and capacity, finally outgrew the water-power and are at the present day operated by steam or by steam and water-power together.

The mills originally established in the valley have enlarged and extended from time to time to keep pace with the growing demand for brass. According to the general law governing the concentration of kindred industries and trades in particular localities, new mills were started there, even after the water power had ceased to be a determining factor in the problem of location. Other advantages, such as the cheapness and accessibility of wood of the variety best suited for annealing purposes, were among the causes that held the trade in the valley. Then, too, there arose a race of workmen skilled from generation to generation in the mixing, rolling and manipulation of brass; and as time went on and competition increased, the production of rolled metal becoming less profitable, many of the rolling-mills began remanufacturing their own metal. Other corporations were formed, some being direct offshoots from the brass mills, until the location became what it is to-day; a great centre for the reworking and consumption of metal. There are many reasons why it is desirable that a brass-mill should not be too far from the place where its product is chiefly consumed, and thus it happens that, while a few brass manufactories are operated in other parts of the country, the Naugatuck Valley still is and probably will remain the seat of the brass-rolling industry in America. Other enterprises, such as the rolling of iron and steel, thrive best where their raw material, their fuel and labor are cheapest and most accessible, transportation, labor and fuel being great factors in the cost of the product; but the brass manufacturer, working a high-priced raw material, and bringing his finished product to the point of nicety in gauge and quality, finds the cost of labor, fuel and transportation factors of less importance relatively, and he is governed largely by other considerations in his choice of locality. Therefore, while the shifting centres of the manufacture of iron and steel are marked throughout the country by abandoned furnaces, the seat of the brass-rolling industry remains to-day where it was established nearly a century ago, it being a

noteworthy fact that nearly all of the brass-mills outside of the State of Connecticut were constructed or are operated by Connecticut men.

Israel Coe, a farmer of Connecticut, John Hungerford, of Connecticut, and Anson G. Phelps, a capitalist of New York, and founder of the house of Phelps, Dodge & Company, were pioneers in brass manufacturing in this country, and in 1834 they built a brass-mill at Wolcottville, now Torrington, Conn. Previous to 1830 brass was imported, or manufactured here in a very primitive way. As early as 1811 James G. Moffett of New York rolled brass in small quantities, using for power a sweep actuated by oxen. In 1802 the manufacture of gilt buttons was begun in Connecticut by Abel Porter & Company. At that time these buttons were articles of fashionable use. To obtain brass for this purpose the mixture was cast in ingots at Waterbury and taken to Bradleyville, near Litchfield, Conn., where there was an iron-mill driven by water power; here it was broken down and rolled into strips, and returned in a rough state to the button factory in Waterbury, where it was rolled thinner by being passed between two rolls two inches in diameter, driven by horse power. The copper for brass-making was obtained from old boilers which had been used in distilleries and in sugar-making. This copper was cast into ingots and mixed with spelter, which was obtained from abroad. In 1808 Abel Porter & Company purchased the water power later owned by the Scovill Manufacturing Company at Waterbury, and soon afterward put in rolls suitable for breaking down and finishing brass. For a period of about 20 years they rolled brass, but it does not appear that their production was any more than enough to supply their own requirements. In 1830 the firm of Holmes, Hotchkiss, Brown & Elton established a mill and engaged in the manufacture of sheet brass at Waterbury. This was substantially the beginning of the sheet-brass business in America, although the metal, in small quantities, may have been occasionally supplied to consumers before that time by the firm of J. M. L. & W. H. Scovill and by Benedict & Coe, of Waterbury.

There was at that time also a demand for brass kettles, which were manufactured in England by a process known as the "battery" process: that is, they were hammered into shape from metal blanks. The establishment of the mill at Torrington, at the head of the Naugatuck Valley, in 1834, was for the purpose of rolling brass for use in manufacturing these kettles and to supply the growing demand of the button factories. A small rolling-mill was built, with machinery imported from England, and Israel Holmes of Waterbury was engaged as manager of the mill. There was great difficulty in securing workmen competent to carry on the business. Mr. Holmes was sent to England and succeeded in procuring a few experienced men. He afterward made another trip abroad for the same purpose, but the English manufacturers, fearful of losing their American trade, endeavored to prevent him from hiring their men, and it was with great difficulty and some danger to himself that he succeeded in embarking a colony of workmen and their families, about 30 persons in all. These were landed at Philadelphia, taken in a schooner from there to Hartford, Conn., from which place they proceeded on foot through the woods, a distance of 25 miles, to Torrington.

From this small beginning, and with no end of difficulty and discouragement, the enterprise continued to grow. Local competition arose, and in 1840 Edwin Hodges of West Torrington started a mill for the purpose of making brass kettles and also for drawing brass wire. This seems to have been the first brass wire-drawing establishment in this country. It was located in Cotton Hollow, in the town of Torrington. The enterprise was unsuccessful and the mill was soon closed, with the loss of all the capital invested. In 1841 the original enterprise at Torrington was made into a stock company, with a capital of $56,000. It was named The Wolcottville Brass Company, and the incorporators were John Hungerford, Anson G. Phelps and Israel Coe. The records of this company for the first few years of its existence contain some interesting details. The copper used was imported from Chile, or was obtained in the form of old copper, which was collected from different places throughout the country. The price of copper was then 18¾ cents per pound. Spelter, which was imported, cost 8⅜ cents per pound. The fuel used was mainly wood, but some Lehigh coal was procured, which cost, at Hartford, $8.43 per ton, to which was to be added the cost of transportation by teams from Hartford to Wolcottville. Firebrick for the furnaces cost $60 per 1,000. The manufactured product, in the form of rolled and sheet brass, was valued at 26 to 30 cents per pound. It was taken by teams either to Waterbury or 25 miles across a hilly country to Hartford, and from there shipped on sloops to New York. Upon the site of the works occupied by the Wolcottville Brass Company are to-day the factories of the Coe branch of The American Brass Company. The name of Anson G. Phelps is perpetuated by the city of Ansonia, the Ansonia branch of The American Brass Company and the Ansonia Clock Company, as well as by the firm of Phelps, Dodge & Company, Inc., which he founded; and the name of Israel Holmes appeared in the title of the corporation of Holmes, Booth & Haydens, of Waterbury.

The decade from 1840 to 1850 saw the birth of many of the prominent brass manufacturing corporations of the present day. In 1843 a joint-stock company at Waterbury was organized under the title of the Benedict & Burnham Manufacturing Company, with a paid-up capital of $100,000. Aaron Benedict was president and treasurer and John S. Mitchell secretary. Mr. Aaron Benedict continued at the head of the company until his death in 1873.

The Waterbury Brass Company began business in 1845 with a capital of $40,000. Among the incorporators were John P. Elton, Lyman W. Coe, Israel Holmes and Hobart V. Welton.

In 1849 the Naugatuck Railroad was completed and the product of the valley mills was thereafter shipped by rail to tidewater at Bridgeport.

In 1848 Thomas Wallace and his sons, John, William and Thomas, began the business of wire drawing at Birmingham, Conn. Their cash capital was $500. Their knowledge of their trade enabled them to increase their business and in a few years they built a factory at Ansonia, which has been greatly enlarged and

is now owned and operated by the Coe branch of The American Brass Company.

The Scovill Manufacturing Company of Waterbury succeeded the firm of J. M. L. & W. H. Scovill and was incorporated in 1850 with a capital of $200,000, which has since been increased to $5,000,000. They now manufacture brass, German silver, etc., and are extensive remanufacturers of metal.

The Coe Brass Manufacturing Company of Torrington, Conn., was founded by Lyman W. Coe in 1863, and succeeded the Wolcottville Brass Company. Lyman W. Coe, the son of Israel Coe, was the president of the corporation, which began business with a capital of $100,000. Their capital has been increased from time to time and they are now merged in The American Brass Company.

In 1844 Anson G. Phelps purchased extensive lands in the vicinity of what is now the city of Ansonia, which was founded by him and named in his honor. He constructed a dam across the Naugatuck River, a canal, large reservoirs for water power and built a mill for rolling copper. The firm of Phelps, Dodge & Company had for some years prior to 1844 operated a copper rolling-mill at Birmingham, Conn. The water privilege at Ansonia is now owned and operated by the Ansonia Land and Water-Power Company and is the source of water power for the city of Ansonia. Mr. Phelps brought from the Wolcottville works J. H. Bartholomew and George P. Cowles, who managed the business at Ansonia under the name of the Ansonia Brass and Battery Company, the term "battery" being indicative of the process by which brass kettles were hammered from metal blanks. This method of making kettles was in use until 1851, when it gave place to a patented process for spinning kettles from circular blanks of metal. The business of the Ansonia Brass and Battery Company was conducted by the firm of Phelps, Dodge & Company of New York. A brass-mill was built, and later a wire-mill. The company afterward engaged in the manufacture of clocks. In 1869 this manufacturing enterprise was incorporated under the name of the Ansonia Brass and Copper Company. In 1877 the manufacture and sale of clocks had increased to such an extent that it was decided to form a new joint-stock corporation under the name of The Ansonia Clock Company, which began business on 1 Jan. 1878. The location of this company's business was transferred to Brooklyn, N. Y., where large factories were erected and are now in operation, producing clocks and watches which are marketed in every part of the world.

The American Brass Company, incorporated under a special charter from the State of Connecticut, and now owned by the Anaconda Copper Company which controls the brass industry, began business in January 1900. It was a merger of the Coe Brass Manufacturing Company, The Ansonia Brass & Copper Company, The Benedict & Burnham Manufacturing Company. The Waterbury Brass Company, The Holmes, Booth & Haydens Company, The Chicago Brass Company.

Taking into account the capital employed and the magnitude of its operations in brass and copper this company is the most important brass manufacturing enterprise in the world and the largest single consumer of copper, giving employment to about 15,000 persons.

During many years brass manufacturing was conducted on what would now be regarded as a very small scale, and, although the methods pursued at the present day are substantially the same as at the beginning, great progress has been made in cheapening these methods and improving the quality of the articles manufactured. It is stated that in the early forties it was customary for the manufacturers at Waterbury annually to appoint a committee to make the long journey to Baltimore for the purpose of purchasing copper for the season's supply. At that time the purchase of 500,000 pounds of copper was sufficient for a year's supply for these manufacturers. At present that quantity would not supply the demand of the Naugatuck Valley for one day.

Copper and spelter being the metals from which brass is made, a brief account of the sources of supply from which these materials are obtained will throw some light upon the development of the business of brass and copper rolling. The first copper mine worked in the United States was the Simsbury mine at Granby, in Connecticut. The record of this mine extends back to the year 1705. It was worked until 1770, but was not profitable, and only a small quantity of ore was taken out. During the War of the Revolution it was used as a prison. About the year 1719, the Schuyler mine, near Belleville, N. J., was opened and became one of a number of small mines which were worked in that section of the country for a series of years following. The Gap mine, in Lancaster, Pa., was started in 1732. The production of copper from all these openings, however, was of very little commercial importance, and until the Lake Superior region became a source of supply, the consumers of copper in the United States had to procure their raw material in Chile. It was brought to this country in the form of pigs, and refined near Boston, at Baltimore and at other points along the coast. In 1844 the Cliff mine, near Eagle River, Lake Superior, was opened, and in 1845 regular records of production were begun. The great development of the copper-mining industry at Lake Superior soon placed the United States in the front ranks of the copper-producing countries of the world, and the product of these mines, being of a quality much finer than the copper produced abroad, naturally took the place of the foreign product for home consumption. Copper production in the United States from 1845 to 1880 kept pace with home consumption, a comparatively small quantity being exported up to the last-named period, so that the record of the copper produced in the United States between the periods named will indicate the progress made in manufactures of brass and copper. Beginning in 1845 with a product of 100 tons (which was much less than the quantity required for home consumption), the record for periods of 10 years is as follows: 1850, 650 tons; 1860, 7,200 tons; 1870, 12,600 tons; 1880, 27,000 tons; 1890, 130,000 tons; 1900, 303,000 tons; 1920, 604,531 tons; 1924, 817,150 tons; 1937, 1,228,000 tons.

Comparatively little fine copper was imported to the United States after 1860. In 1879 the

Lake Superior region furnished about 83 per cent of the total quantity of copper produced here, but after 1880 the opening of the copper-mining regions of Arizona and Montana increased the output largely beyond the quantity required for domestic use. A heavy exportation at once followed, and this country became one of the world's great sources of supply.

The Lake Superior district includes the first notable deposits of copper discovered on the American continent. This district was the greatest producer for half a century; the product is still very large, the Michigan output in 1937 being 84,751,478 pounds. The copper found there is remarkably pure, and is called Lake copper, being marketed without electrolytic refining, as is necessary with most other coppers. The Rocky Mountain copper deposits became of commercial importance about 1868, when the Butte development got under way. Three great fields have opened up in the Rockies, outdistancing the great Lake deposits. In 1937 the Arizona production was 580,493,036 pounds, over 10 per cent of the entire world's production. The same year Utah produced 404,168,742 pounds, or over half as much as the whole country produced in 1900. Montana, with 280,662,270 pounds in 1937, had slightly less than half the 1900 total, at which time she produced nearly 45 per cent of the United States' output. Nevada and New Mexico have been added to the States producing over 50,000,000 pounds annually, the former with 149,963,847 pounds in 1937, and the latter, 63,573,985 pounds. In 1900 Nevada had been credited with only 408,000 pounds, and New Mexico with 4,169,000 pounds. There are at least seven other States which produce copper in appreciable quantities, besides the territory of Alaska.

The four great copper-producing districts of the United States are the Butte smelters, which began production in 1868; the Lake Superior district, which has produced since 1845; the Bisbee, Ariz., district, which was opened in 1880, and the Bingham Canyon district which is in Utah. Arizona has been the leading copper-producing State of the United States since 1910 and now produces over 40 per cent of the entire output of the country. The quantity of copper produced in the United States in 1937, as reported by the United States Geological Survey, was as follows:

	Pounds
Refined copper produced by the regular refining companies from the smelters of the United States	1,669,322,278
Of foreign origin	559,750,000
Total refinery production, new copper	2,229,072,278
Imports of refined copper	14,974,000
Total new refined copper available	2,244,046,278

In 1937 the refined copper produced in the United States from domestic and foreign ores totaled 1,481,569 short tons.

The consumption of new copper in the United States in 1937 is estimated to have been 1,391,101,079 pounds, to which may be added old copper from sundry sources such as old copper and brass, scrap, etc., in excess of 1,000,000,000 pounds. This estimate includes at least 300,000,000 pounds of copper produced by remelting clean scrap.

A fair estimate of the average price of copper in the United States from 1845 to 1859 is 20 cents per pound. From 1859 to 1876 the yearly average price of copper varied from 20½ cents to 32 cents per pound, with the exception that in the years 1864 and 1865 the price was advanced, so that in 1864 the average price of Lake Superior copper was 46¼ cents per pound and in 1865 36¼ cents. After 1876 there was a gradual decline in the yearly average price, which was 18⅝ cents in 1877 and 11¼ cents in 1887. In 1931 the price touched about 6 cents per pound, which is the lowest point recorded.

In 1899 the increased demand for copper in the United States and abroad was the cause of a rapid advance in the price of the metal, which sold as high as 18 cents per pound. The large exports (159,000 tons in the year 1900), and the steady increase in the demand for home consumption, kept the price between 16 and 17 cents until December 1901.

In the fall of 1901 it became known that a considerable stock of unsold copper had accumulated in the hands of one of the largest of the producing mining companies. Meanwhile, owing to decreased consumption abroad, the exports of copper had fallen off at the rate of about 65,000 tons per annum (the total quantity exported in 1901 being about 95,366 tons). Toward the end of the year there was a sharp decline in the London market, followed by a series of reductions in the price of copper in New York, which, emanating from one source, brought the price, within a period of 30 days, from 16¾ cents down to 11 cents per pound. The first effect of this action was to check consumption, but when it was known that copper could be bought for forward delivery at 11 cents per pound, the demand for manufactured copper increased to such an extent that large buying of the raw material followed and the price of copper quickly advanced to 12½ cents. The average price of Lake copper during 1902 was 11⅞ cents, and in 1903 about 13½. The average price obtained by the Lake Superior mines for copper during 30 years previous to 1903 was about 12¼ cents. From 1903 to 1913 the average price of electrolytic copper was about 15 cents per pound; in 1916 and 1917 slightly above 27 cents—the record; fell to 12.3 in 1921; reached 18.1 in 1929.

Since we became great exporters of copper, the price of this metal in the United States has been nearly at a parity with the price in Europe. With increased production the cost of mining has been greatly reduced, while improvements in metallurgy and methods of electrolytic extraction have brought into the market great quantities of copper suitable for the finest work from sources which formerly furnished only coarse and ordinary grades of material. In former years the tariff upon copper affected the price of the raw material in this country, often enabling the mining companies to obtain from the consumer at home a higher rate than that which ruled abroad. The price of copper in this country was sometimes sustained by arrangement between the mining companies, who would market the copper here at a fixed price and ship their surplus product abroad at a considerably lower rate. The American brass manufacturer was, therefore, usually confined to a home market for his product, and the statement that, in certain cases, he succeeded in taking large foreign contracts for brass, with the disadvantage of having to pay a higher price

than his competitor abroad, not only for his raw material but for his labor and supplies, is the best possible tribute to the excellent quality of his work. Ingot copper was admitted to this country, duty free, until the act of 30 July 1846, when a duty of 5 per cent was imposed. The act of 3 March 1857 restored copper to the free list. Subsequently duties were imposed upon copper: in 1861 of two cents per pound, and after that of from two and a half to five cents per pound. The McKinley Bill made the duty one and a quarter cents per pound, and at present ingot copper is on the free list.

The first refined spelter produced in this country was made in the year 1856, at Bethlehem, Pa., from ores mined there, and it was sent to the government arsenal at Washington. Up to 1865 or 1866 the spelter used by brass manufacturers was imported from Germany and Belgium. In 1867 the Missouri Zinc Company, at Carondelet, Mo., began to make spelter from Wisconsin ores. The first year they made about 1,800 tons; the next year about 2,500 tons. This was used in the United States. In 1869 the first zinc ores were discovered in southwestern Missouri, and since then the development of the zinc industry has been constantly increasing. The output of the year 1903 was 157,900 short tons of metallic zinc or spelter. The production and consumption of spelter in the United States in 1914, 1924 and 1929 is estimated by the United States Geological Survey to be as follows:

	Short tons	Value
1914	353,449	$ 36,414,000
1924	515,831	67,058,000
1929	611,209	80,680,000

The apparent consumption of spelter was 299,125 short tons in 1914, 448,257 in 1924 and 564,049 in 1929. The abnormal demand for high grade spelter in 1915, for use in the manufacture of brass for ammunition exported to Europe, caused an unprecedented advance in the price of the metal which ranged from 6 to 25 cents per pound. The average selling price for prime western spelter was about 12.4 cents per pound but sales of some of the higher grades were made at more than double that price. The number of retorts at zinc smelters increased from 115,114 at the close of 1914 to 156,658 at the close of 1915. And it is estimated that at the end of 1916 the spelter-producing capacity of the country was about 900,000 tons. American brass manufacturers have used domestic spelter almost exclusively for several decades, the quality of the American product being superior to that of the foreign article. One of the finest grades of spelter is produced in New Jersey and is sold at a high price. At no time within the past 30 years has spelter been admitted to the United States free of duty. The duty under the McKinley Bill was 1½ cents per pound. Subsequently it was made 1 cent per pound, and the duty at present is 1¼ cents per pound.

On 13 Jan. 1801, Paul Revere, of Revolutionary fame, wrote to a friend in London, requesting him to go down to Maidenhead, where rolling machinery was manufactured, and ascertain the price of a pair of rolls 9 inches in diameter and 20 inches long, for making sheet copper. Colonel Revere was a silversmith, and had previously corresponded with Benjamin Stoddard, Secretary of the Navy, upon the subject of copper rolling. It is not known whether or not these rolls were procured at that time, but in January 1801, Colonel Revere purchased an old powder-mill at Canton, Mass., where he began the production of sheet copper. The business has been carried on continuously since that time, and is now incorporated under the name of the Revere Copper Company. Among the names of those originally connected with this enterprise are Joseph A. Revere, James Davis, John Revere and S. T. Snow. This company was finally consolidated with the Taunton-New Bedford Copper Company.

In 1812 the Soho Copper Company was established in Belleville, N. J., where there is a good water power and transportation by railroad and the Passaic River. The originator of this enterprise was Harmon Hendricks, the son of Uriah Hendricks, who was an importer of copper and metals. Some of the buildings were of brick, roofed with tiles imported from Europe. The rolling-mill was of wood and contained one pair of breaking-down rolls, one pair of sheet rolls and one pair of bolt rolls, all of which were imported from England. The plant and machinery cost $50,000, and were intended for the purpose of furnishing the United States government with heavy copper sheets for boilers and bolts for shipbuilding, during the War of 1812. This business has descended from father to son in a direct line, until it is now in the hands of the fourth and fifth generations, and is known as the "Belleville Copper Rolling Mills," operated by Hendricks Brothers. In the year 1815 ingot copper sold for 18½ cents per pound and the price of copper sheets was 39 cents per pound.

The Gunpowder Copper Works were built in 1817 on the Gunpowder River, 10 miles from Baltimore, by Levi Hollingsworth. Water power was used in manufacturing. In 1866 the rolling-mill was transferred to Canton. It is now operated by the Baltimore Copper Smelting & Rolling Company, who are engaged in smelting and in the manufacture of blue vitriol and sulphuric acid.

The manufacture of yellow metal for sheathing vessels was the subject of a patent by H. F. Muntz, of Birmingham, England, about the year 1840. This mixture, which contains a large percentage of spelter and can be rolled while hot, being cheaper than copper, naturally came largely into use for ship-sheathing. It was first made in this country by the Revere Copper Company, within a year or two after its production in England. Later, it was made by the Taunton Copper Manufacturing Company, the New Bedford Copper Company and the Bridgewater Iron Company. The decline of American ship-building, and legislation permitting American vessels engaged in foreign trade to use the foreign metal without payment of duty, have greatly decreased the demand for yellow metal in the United States.

The causes that have tended to localize the manufacture of sheet brass do not affect the rolling of copper. The makers of sheet copper usually do not remanufacture their product. So that, while most of the brass-mills are located in Connecticut, the copper-mills are distributed throughout the country: in Massachusetts, Connecticut, New York, New Jersey, Pennsylvania, Michigan and Illinois.

The manufacture of seamless tubes of brass and copper is an important part of the brass

business. These tubes are made in the Naugatuck Valley by The American Brass Company and also by the American Seamless Tube Company of Boston, and by other manufacturers. Early in 1848, Joseph Cotton, Joseph H. Cotton, William E. Coffin, Holmes Hinckley and Daniel F. Child, all of Boston, despatched to England an engineer, Joseph Fox, to learn how to make seamless brass tubes, paying a large sum to Messrs. Green and Alston, the English patentees, for the instruction of Mr. Fox, and the right to make tubes by their process in the United States. Previous to that time all copper and brass tubes for use in locomotive and marine boilers and for the hundreds of other uses to which tubes were put, were brazed: that is, made of strips of metal put in a rounded form and their edges brazed together. In 1850 the gentlemen before named organized a corporation called the American Tube Works, of Boston, and began the manufacture of seamless drawn brass tubes. Such tubes have taken the place of the brazed tubes in all cases where steam or other high pressures are involved.

Statistics compiled by the United States Bureau of the Census show that there were 1,106 establishments in the United States engaged in the manufacture of brass, bronze and other non-ferrous alloys and manufactures of these alloys and of copper in 1927. These establishments gave employment to 64,187 wage-earners who received $92,894,000 in wages. Materials used by these industries with the addition of supplies, fuel and power, cost $327,605,000; products turned out by them had a value of $519,892,000, the value added by manufacture having been $192,288,000. These industries used 404,512 horsepower, and had a maximum possible output, it is estimated, of 30 per cent greater than their actual output. The industry ranks 31st among the great industries of the United States in value of output, but not in the number of operatives.

There were in the same year 26 establishments in the United States engaged in smelting and refining copper, most of them engaged in smelting only; four in refining only, and some in both smelting and refining. Collectively, these 26 establishments gave employment to a total of 13,924 wage-earners who received $20,582,000 in wages. Materials used by these industries cost $527,764,000, and they turned out products valued at $609,299,000, the value added by manufacture having been, therefore, $81,535,000.

Brass founders or manufacturers of articles of cast brass are not included in the foregoing figures. That is a separate branch of business, and it is carried on by a great number of foundries in the United States, consuming a large quantity of ingot copper and of old metal. Many manufacturing concerns, also, have their own foundries, where metal is cast, to be used in their various departments.

Early in the year 1915 it became evident that a large quantity of copper and spelter would be required, by the mills of the United States, for use in the manufacture of ammunition for the warring nations of Europe, and the price of these metals rapidly advanced until, in 1916, copper was quoted at 34 cents per pound and spelter at from 18 to 30 cents according to the quality of the metal and the time of delivery, the highest price being paid for immediate requirements. Brass rolling-mills running day and night were unable to supply the demand for brass; existing mills increased their facilities; new mills were started; old and disused mills were put in operation; wages were advanced; labor became scarce and serious strikes occurred, for the first time in the history of the business. Brass rolling became very profitable and the shares of corporations engaged in that business doubled in value within a year.

In brass rolling-mills the copper is received in the form of ingots and the spelter in the form of plates which are broken when required for use. The copper is melted in crucibles and the spelter is then added in the proportion required, the standard mixture being about two parts copper to one part spelter. This mixture and those containing a higher percentage of copper are rolled and worked when cold. The combination of 60 pounds of copper with 40 pounds of spelter is known as yellow metal and is usually rolled while hot into sheets and rods. The melted brass is poured from the crucibles into sectional molds from which when cooled it is taken in the form of slabs, approximately of the width required for the finished product. These slabs are then reduced and elongated by passing through rolls of chilled iron. Frequent annealing is required between the successive passes and the oxide forming upon the surface of the metal in the process of annealing is removed by baths of dilute sulphuric acid. Brass rods are drawn from round bars by successive passes through dies on draw-benches. Brass wire is produced by drawing the metal through a succession of dies by means of revolving drums on which the wire is coiled. Seamless brass and copper tubes are usually cast in hollow form round a core and finished on draw-benches by drawing through dies over mandrels. Another process consists of piercing a bar of metal by a steel mandrel over which the metal is drawn by the action of conical rolls revolving at a high speed; the shell thus formed is then drawn into a tube in the ordinary manner. Brass rods and tubes of intricate shape are formed by a process of extrusion by means of which the metal, after being heated to a temperature of about 1,000° F., is placed in a cylindrical container at one end of which is the die and, upon pressure being applied at the opposite end by means of a hydraulic ram, the metal, which is in plastic condition, is forced through the die, issuing therefrom as rods or tubes of the required section and of a length governed by the quantity of metal placed in the container. In this way metallic sections are produced in complex designs with re-entering angles which it would be impossible to roll or draw. An admixture of brass and nickel produces the white metal known as German silver, used in the manufacture of spoons, forks and other articles which, when plated, have the appearance of silverware. Sheet copper and copper rods are rolled at a red heat from cast plates and bars and, when a fine surface is required, they are finished by cold rolling or drawing. In the rolling of brass and copper the accumulation of clean scrap metal is remelted and used.

ALFRED A. COWLES,
Late Vice-President of The American Brass Company.

COPPER CLIFF, Canada, a town in the Sudbury district of Ontario, on the Sault Sainte Marie branch of the Canadian Pacific Railway, four miles west of Sudbury. The neighborhood is rich in copper and nickel. An electric railway now connects with Sudbury. Pop. (1939) 3,875.

COPPERAS, the commercial name for ferrous sulphate, or green vitriol. (See IRON). Its formula is $FeSO_4 7H_2O$. Copperas occurs native, as the mineral melanterite (q.v.), commonly in connection with deposits of pyrites, from which it is derived by oxidation.

COPPER, or ATNA, RIVER, a stream in Alaska, rising in the neighborhood of Mount Wrangell, flowing in a generally southerly direction west of that mountain, and emptying into the Gulf of Alaska about 30 miles west of Chilkat. The length of the river is a little over 300 miles. Its name is due to the alleged fact that its waters hold copper in solution. Its basin has an area of about 23,000 square miles. Its course reveals a reverse topography, for though it originates in a mountainous region, its upper course lies through a broad plain, while its lower course carries it through the Chugach Mountains. The Copper River and Northwestern Railroad runs from the seaport Cordova to the river and up along it to the Chitina, eastward to the Kennecott copper camp.

COPPERFIELD, David. See DAVID COPPERFIELD.

COPPERHEAD (*Ancistrodon contortrix*), the most widely distributed, and in many places the most abundant of the venomous snakes occurring in the eastern United States. It belongs to the family *Crotalidæ* (q.v.), but with the water moccasin belongs to a genus (*Ancistrodon*), distinguished from the rattlesnakes by the absence of rattles, while the copperhead is peculiar in the presence of a small additional plate between the eye and nostril. The copperhead seldom exceeds a length of three feet. It is brown, with a series of dark blotches on the back, and the triangular head is a bronzy red, from which circumstance it takes its name, while the white color of the interior of the mouth has given rise to another of its names, that of cottonmouth, also applied to the water moccasin. It is sometimes called the red viper. Like other poisonous snakes the copperhead has been exterminated in the thickly settled parts of the northern States, but is still abundant in unsettled regions and in the South. It is partial both to the neighborhood of water and to dry rocky hills and, owing to its activity, its silent approach and its irascible temper, is justly feared by man and the lower animals, including non-venomous snakes. Some of the latter, as the blacksnake, will, however, attack and eat it. The customary food of the copperhead consists of small birds and mammals. About seven or eight young are produced at a time, this snake being viviparous; it is said that when pregnant a large number of females will sometimes twine themselves together, whence the epithet «contortrix.» As a poisonous snake the copperhead, as well as many harmless American snakes, is sometimes called an adder or viper, though in common with all related poisonous serpents of North America, it differs from the true vipers in the presence of the preorbital sensory pit. In England adder is the name applied to the only native venomous serpent, the *Pelias berus.*

COPPERHEADS, a name applied in 1862 and throughout the Civil War to members of the Democratic party in the northern States who violently opposed the prosecution of the War. They were not necessarily in sympathy with the South, but in all events they held that the Confederacy could never be conquered, and that the attempt to coerce the seceding States was hopeless and illegal. The name was generally indicative of a treacherous character, and was a reference to the habit of the copperhead snake, which strikes without warning. Another explanation of the name is that it came from the button cut out of a copper cent, on which was the head of the Goddess of Liberty, worn by the opponents of the war. The most prominent and obnoxious of the copperheads was Clement L. Vallandigham (q.v.).

COPPERMINE RIVER, in Canada, near Coppermine Mountain. It has its source in Point Lake and flows into Coronation Gulf, an arm of the Arctic Ocean, near Duke of York's Archipelago, lat. 68° N., long. 116° W. Its length is about 325 miles; but the large number of waterfalls along its course render it useless for any travel except by light canoes.

COPPICE. See COPSE.

COPPIN, Fanny Muriel Jackson, American negro educator: b. Washington, D. C., 1846; d. Philadelphia, 21 Jan. 1913. She was born in slavery and her freedom was purchased by an aunt when Fanny was about 12 years of age. At 15 she went to Newport, entered the service of the Calvert family, and in her spare time managed to acquire the rudiments of an education. Later she entered Oberlin College, and was the first colored woman in the United States to graduate from a recognized college. She taught a class in the preparatory department at Oberlin with conspicuous success and soon after the outbreak of the Civil War was called to the Institute for Colored Youth in Philadelphia, of which she became director in 1869. For 35 years her career in Philadelphia was one of intense activity, acknowledged ability as an educator and distinction as a leader in every good cause for the promotion of the betterment of the colored people of her city and the country at large. She organized the Colored Woman's Exchange, and an Industrial School as part of the Institute. In 1888 she visited England to attend the Missionary Congress and there most eloquently pleaded her cause. In 1881 she married the Rev. Levi J. Coppin, who in 1900 was elected bishop and assigned to work in South Africa. She resigned her connection with the Institute in Philadelphia and set about founding the Bethel Institute at Cape Town. The last months of her life were spent in preparing for the press her 'Reminiscences of School Life and Notes on Teaching.'

COPPINGER, John Joseph, American military officer: b. Ireland, 11 Oct. 1834; d. 1909. After obtaining a military education in Ireland he went to Rome, serving in the papal army as aide-de-camp. He came to the United States in 1861 and was given a commission in the Union army, rising to the rank of brigadier-general in the regular army in 1895. In the

war with Spain, as major-general of volunteers, he commanded the 4th Army Corps in Porto Rico. He married Alice, daughter of the late James G. Blaine (q.v.). He was retired in 1898.

COPRA, the dried kernel of the cocoanut, from which the oil has not yet been expressed, a considerable article of commerce in some tropical regions. Samoa and the Fiji Islands export more than 10,000 tons annually, and the Philippine Islands about 200,000 tons. From it cocoanut oil and cocoa butter are manufactured, and the residuum after expression is an excellent fodder, with many of the nutritive properties of cottonseed-oil cake. Copra, either sun-dried or kiln-dried, contains 50–65 per cent of oil, while hot air dried may run as much as 74 per cent.

COPROLITES, the term originally applied to the fossil excrements of extinct animals, especially fishes and reptiles, found most abundantly in the lias, greensand and Suffolk crag. They consist chiefly of phosphates of calcium (from 50 to 75 per cent) and magnesium, and the carbonates of the same metals, and organic matter, and as the fertilizing properties of these are well known, coprolites have been largely used as a manure. For this purpose they are reduced to powder and used as ground bones, or treated with sulphuric acid, so as as to form superphosphate of lime. To the scientist these remains have a definite value as indicating the prey of the animal in question and the nature of its intestinal structure.

COPSE, kŏps, a cultivated wood, where the trees are cut periodically, before they attain timber size, each succeeding crop being cut from the stumps of the first growth. A copse or coppice is sometimes used as an ornamental growth, where large trees would not be desirable, but their chief use is as a source of profit. When cultivated under the rules of scientific forestry, they may be made a very valuable adjunct to the farm lands. The practice is not common in America, where the idea of profit from woodland is that the land must be allowed to grow up to timber, and then be entirely denuded. In Europe, particularly in England, the most valuable tree thus employed is the oak, which is cut at intervals varying, according to soil and climate, from 12 to 30 years; and after paying all expenses it often yields from $150 to $250 per acre in bark used for tanning and in wood convertible into wheel-spokes, or applicable to other purposes. The stems, cut over near the ground, are carefully dressed and rounded, so as to prevent them from rotting; in a short time a number of shoots appear, all of which are thinned away except three or four of the most promising, which are left to grow till they again become fit for another cutting. When plantations are extensive, the method usually followed is not to allow all the copse to come to maturity at the same time, but to divide it into a number of sections and to cut one of them annually, so as to yield a revenue with as much regularity, and not infrequently to as large an amount as an equal quantity of land under cultivation. For instance, a copse of 100 acres, on the assumption that it may be profitably cut after 20 years' growth, is divided into 20 sections of five acres each. By cutting only one of these sections annually a perpetual succession of cuttings is obtained, yielding, on the most moderate calculation, a clear income of at least $500 per annum. The proprietors of many of the rocky glens of Great Britain, by pursuing this method, have materially increased the value of their estates. The other kinds of wood commonly used for copse are chestnut, which, from its durability, even when partly inserted in the ground, is valuable for posts, etc.; ash, preferred for all purposes where strength and elasticity are required; and hazel, admirably adapted for barrel hoops, and in great demand for crates in the vicinity of potteries. The willow, well known for its uses in basket-making, being cut down regularly after every year's growth, scarcely falls under the head of copse. In some continental countries the copse is the source of the whole fuel supply.

COPTIC LANGUAGES, the language formerly spoken by the Copts or Egyptian Christians and regarded as the direct descendant of the ancient sacred language of the Egyptians. As such it has afforded to Champollion, Dr. Young and others the key to the interpretation of the Egyptian hieroglyphic inscriptions. At the time of the introduction of Christianity among the Copts the hieroglyphic, hieratic and demotic modes of writing previously in use in Egypt were abandoned, and the Greek alphabet was adopted, with the addition of six characters of the demotic alphabet, which were retained because the equivalents to them were wanting in the Greek alphabet. These six letters represented *kh, h, f,* the English *j* and two forms of *sh.* By the time that this change was made the Coptic language was no longer the same with the ancient sacred language, but had adopted a number of words from the vernacular language which was spoken in Egypt alongside of the former, besides a large number of others from the Greek, the Latin, the Arabic and other sources. It still remained, however, essentially Egyptian. The Coptic language is monosyllabic in character. All its radical forms are monosyllables, and whenever a polysyllabic word is met with it may be at once affirmed that the word is either a derivative or a compound. As a rule the radicals are capable of certain modifications of form, which always express a modification also of the sense. The meaning of the radical monosyllables is in fact changed by the juxtaposition of other monosyllables, which are the usual signs of genders, numbers, persons, moods and tenses. The feminine is sometimes formed by a modification of the vowel of the masculine. In the Coptic root syllables there are often final consonants which do not form part of the root. These are called paragogic letters, and can only be explained as instances of the caprice of pronunciation, or as being originally part of the root both in spelling and pronunciation, although in course of time they have been dropped so far as the pronunciation is concerned. According to the German philologist, Schwartze, the Coptic may be taken as forming a family of languages analogous to the Semitic in its grammar, and allied to the Indo-European languages in its roots. This opinion is supported by various other philologists, such as Bunsen, Meier and Bötticher, but it is contested by others, among them Pott, Ewald, Wenrich and Renan.

The Coptic language is divided into three dialects—the Theban, which was spoken in Upper Egypt, and which is the best preserved of the three; the Memphitic, or Coptic, strictly so called, which was spoken in Lower Egypt; and the Bashmuric, which was spoken in the Delta. Of the last the literary remains are very scanty, but it is that which comes nearest to the hieroglyphic language of the ancient Egyptians. After the Arabian conquest of Egypt the Coptic language gradually ceased to be spoken, and as early as the 10th century it was no longer in use in Lower Egypt, except in their church liturgies; in Upper Egypt, however, it maintained itself for some centuries longer, but here also it was at last obliged to give way to the Arabic. The theological writings in use among the Coptic Christians, however, are still written in the Coptic language, but an Arabic translation always accompanies them. In the schools the children learn the Gospels and the epistles of the New Testament in Coptic as well as Arabic, but they are no longer taught the former language grammatically. In the various libraries of Europe there are numerous Coptic manuscripts, but most of them are of little interest. The Coptic literature is almost entirely of a religious character, the works written in it comprising portions of the Old Testament, the Acts, sermons and homilies, martyrologies, etc. Translations of the Pentateuch and some other books of the Old Testament and of the Gospels into Coptic have been published at Rome. One of the most valuable discoveries of Coptic literature—practically the whole library of the old Coptic monastery of Saint Michael in the Egyptian Fayyûm, was acquired by the late J. Pierpont Morgan in 1911, and placed by him in the J. Pierpont Morgan Library in New York city. It consisted of 50 volumes, and these are being edited for publication by Professor Hyvernat of the Catholic University of Washington. The larger part consists of manuscripts of books of the Bible of the 2d century of our era, and the remainder of liturgical books and treatises by the old monks of Alexandria. These are the oldest manuscripts known, and the fine bindings are the choicest and oldest existing in any library. Materials for the study of the Coptic language will be found in the grammars of Schwartze (Berlin 1850), Uhlemann (Leipzig 1854), and Stern (Leipzig 1880), and the dictionaries of Peyron (Turin 1835, still considered the best) and Parthey (Berlin 1844). Consult Loret, 'Manuel de la langue égyptienne.'

COPTINE, a colorless alkaloid which is said to have been found together with berberine in the root of *Coptis trifolia.* Coptine dissolves in sulphuric acid, the solution becoming purple-red when heated; it gives a crystalline precipitate with a solution of mercuric potassium iodide.

COPTIS, a genus of low herbs of the crowfoot family (*Ranunculaceæ.*) It comprises about nine species occurring in the cooler parts of the northern temperate zone. Four species are found in America, three of them on the Pacific Coast. *C. trifolia,* gold-thread or canker-root, grows in damp woods and bogs from Newfoundland to Maryland, and westward and north to Minnesota, British Columbia and Alaska. Its common name of canker-root is given to it because of its use in household medicine as a cure for cankerous affections of the mouth in children. A yellow dye is extracted from the slender yellow root stock. *C. teeta* is used in India as a tonic.

COPTS, a name given to the schismatic Christians of Egypt who are of the Monophysite sect, similar in belief with the Jacobites of Asia. The Monophysites and Jacobites are followers of Dioscurus, patriarch of Alexandria, who was deposed by the Council of Chalcedon in 451, because he maintained there was only one nature in Christ. The Copts were of pure Egyptian blood, and at first were more numerous than their adversaries, the Melkites, who were Greeks in origin and believers in Christ as taught by the Church. Officials who were considered orthodox were sent from Constantinople to govern Egypt, and many of the Copts fled to Upper Egypt and some went to the Arabs. So incensed were they with their rulers that when an opportunity occurred, they betrayed their country to the Saracens, who drove the Greeks and Romans out of the land. But the Copts soon found that their privileges would be of little avail, and their wealth, numbers and respectability rapidly declined, and though rarely intermarrying with their conquerors, and preserving their features, manners and religion unaltered, they soon lost their language, which had resisted the influence of a Grecian court for so many ages. In person and features the Copts differ much from the other natives of Egypt, and are evidently a distinct race. According to the younger Champollion they are the result of a mixture of all the different races that have ruled over Egypt. Reduced by a long course of oppression and misrule to a state of almost degradation, their number and national character have declined; their number was estimated in 1907 at 706,322. Their costume resembles that of the Moslems, but they are in the habit of wearing a black turban for distinction's sake. They also commonly wear a black or dark-colored outer robe. In their general customs there is little to distinguish them from the other inhabitants of the country. They are chiefly employed as clerks, secretaries, etc. The women go out with veiled faces, like the other females of the country. They have numerous schools for their male children, but very few of the females are taught to read. In doctrine they agree almost wholly with the Roman Catholic Church, except on the one point which caused the separation,—the two natures in Christ. They celebrate mass in the old Coptic language, as with them now the Arabic is the common tongue. Their supreme head is the Monophysite patriarch of Alexandria, who is chosen from among the monks; then come the bishops, priests, deacons, inferior clergy and monks. The priests may be married according to the Eastern discipline, and as they receive but little by way of support from their congregations, they are generally engaged in the ordinary occupations of the place in which they live. (See Jacobite Christians; Melchites). They have four seasons of fasting, all of which are scrupulously observed. Their Lent begins nine days earlier than that observed by the Roman Catholic Church. The doctrine of the sacraments does not vary from that of the Latin

Church, but they have a peculiar ritual in the administration of the sacrament of extreme unction, which they give with the sacrament of penance, even when there is no bodily illness, to heal the disease of the soul. The curious custom exists of blessing the bathing water stored in large tanks; and to appease or please the Mohammedans, they have adopted circumcision. Within recent years a large body of the Copts made corporate reunion with the Roman Catholic Church, and there is a Catholic Vicar Apostolic of the Coptic rite for the Copts of Egypt.

The Coptic language flourished from the 3d to the 16th century, but is now extinct as a vernacular. It is of great linguistic importance because of its descent from the Ancient Egyptian. Its literature is of little importance; it borrowed extensively from Greek and Latin but is free from any admixture of Arabic. It was divided into five principal dialects — the Sahidic and Achmimic in Upper Egypt, the Boheiric and Memphitic in Lower Egypt, and the Fayumic, or so-called Bashmuric in Central Egypt. The Sahidic is the liturgical dialect of the Coptic Church and in it is contained by far the greater amount of the Coptic literature extant.

Strzygowski to R. Haupt's 'Katalog 5' (Halle 1905).

COPY (Lat. *copia*, "abundance"). (1) In ancient times, when the art of printing in its improved form was unknown, the copyist was a much esteemed person, and manuscript was multiplied by the laborious process of writing by hand. Some of the Roman slaves were copyists. From the early centuries of Christianity through the Middle Ages, and until the art of printing became popular, there were in each monastery certain monks who were copyists. Their whole time was occupied with transcribing manuscripts of the ancient classics, the writings of the fathers and doctors; but their chief care was the making of copies of the Bible. Often days were spent upon ornamenting an initial letter or in decorating the names of the Deity. The preservation of the Bible in its present form, and of ancient classics in general, is due to the faithful work of the old copyists. Copies of books in those days were of great value, often they were carried under guard from place to place when the owner was traveling, and the copy of the Bible was usually chained in the parish church. (2) The matter, whether in print or manuscript, sent to the printer to be set up in type. (3) An exact reproduction of a work of art made by one other than the original artist; a copy made by the original artist is called a replica; a copy of statue or other piece of sculpture, taken from a mold, is called a cast.

COPYHOLD, in English and Irish law, a tenure of estate by copy of court roll, or a tenure for which the tenant has nothing to show except the rolls made by the steward of the lord's court. Copyhold property cannot be now created, for the foundation on which it rests is, that the property has been possessed time out of mind, by copy of court roll, and that the tenements are within the manor. The method of conveyance of such property is by surrender and admittance, i.e., the holder surrenders it to the lord of the manor, whose steward, on receiving a fee, transfers the copyhold to the person in question, who again swears fealty. The heirs must pay the fee of admittance in order to retain the property. Copyhold land may be converted into freehold by agreement between the lord and the occupants; and the lord or tenant may, by paying a fixed sum or an annual rent (the amount to be fixed by commissioners), compel the enfranchisement of the copyhold. Copyhold was abolished in England by legislation which went into effect 1 Jan. 1926. It does not exist in the United States.

COPYING, a term in general use for a great many different processes, which may be described generally as the reproduction, usually either on an enlarged or reduced scale, of any drawing, map or other work of art. A few of the methods employed may be shortly described. If the copy is to be the same size as the original, the easiest way is to trace it. A piece of tracing-paper is put over the drawing, and the principal lines gone over with pencil. The back of the tracing is then rubbed with black lead or ruddle, and put on the paper on which the copy is to be made; the traced lines are gone over with a hard point, and thus indicated on the paper. Guided by the traced lines, the copy can then be drawn in. When the copy is required of a different size from the original, the simplest way is to sketch it by hand and eye, but where more mechanical accuracy is required, the method of squares is very useful. The original is covered with squares of any convenient size by pencil lines or threads or by tracing paper ruled off in squares; a piece of paper for the copy is prepared with a corresponding number of squares, of a smaller or larger size, according as the copy is wanted smaller or larger. These squares must bear the same proportion to the squares on the original as the copy is to bear to the original. It is then a comparatively easy matter to copy in each square the part of the original in the corresponding square. To avoid confusion if the squares are small, it is well to number them along each side of the drawing. Any drawing consisting principally of straight lines, such as a plan, can be conveniently reduced by constructing a scale to suit the reduced size required. The lines of the original are measured by its scale, and the same proportion of the smaller scale gives the necessary measurement. The pantograph is another means of making a reduction or enlargement,

but is very seldom used now. It is only accurate in a general way. Perhaps the simplest and most exact method is to get the original photographed to the required size; the copy can then be traced on to clean paper as already described.

The copying of letters and other documents for commercial purposes is usually done by means of the ordinary copying-press, which is so familiar in every counting-house as to need no detailed description. A letter written with specially prepared ink is transferred to another piece of paper by means of damp and pressure. Common ink thickened with a little sugar will serve as copying ink. Many modifications of this arrangement have been devised for producing a number of copies of circulars, etc., from one written copy, and are known as «graphs.» A document written with the ink prepared for the purpose is transferred by pressure with the hand to a gelatinous slab, from which as many as 50 or 60 copies, more or less distinct, can be retransferred by rubbing with the hand. A very useful method of manifold writing is largely employed in telegraphic news work, and for duplicating invoices by retail tradesmen. Carbonized paper is put between two, three or more sheets of thin paper, and thus whatever is written on the top sheet with a hard pencil is duplicated on the others. When an indefinite number of copies or any drawing or other subject is required, there are many printing processes which may be employed. Letters or circulars, if written with lithographic ink, can be transferred to stone, and any number printed. Engineers' or architects' drawings, or any other drawing executed in line, can be very successfully reproduced in any size by the photo-lithographic process, which depends on the action of light on citrate of iron and prussiate of potash. (See PHOTOGRAPHY). If required for block or letterpress printing, then any of the zincotpye processes may be employed. By this process, also, plates to reprint steel-engravings can be produced from any printed engraving. For reproducing drawings executed otherwise than in line, photographs from nature, or paintings, there are many other processes.

COPYING MACHINE, any one of a number of contrivances by which one or more copies of a letter or other document may be made. Perhaps the best known is the copying-press. The letter is written with «copying ink,» a writing fluid containing some gummy substance which prevents the ink from soaking into the paper. A sheet of bibulous tissue paper moistened with water to a certain degree is laid on the face of the writing, a sheet of oiled paper is laid on the tissue paper and the letter is placed between boards and put into a press, the platen of which is screwed down tightly. A few seconds' contact of the damp tissue paper with the writing transfers sufficient of the ink from the original to the tissue to make a perfect copy. A number of letters similarly treated may be copied by one operation of the press, and by the use of very thin tissue and longer impression three or four good copies of a letter may be taken. Among copying processes are many that are perhaps rather methods of reproduction in bulk instead of copying in a more limited way, being somewhat akin to printing. Among these are lithography (q.v.) and the mimeographic process. The mimeograph consists of a stylus, moving over a sheet of tissue paper, coated on one side with some sensitive material. This paper is placed on a steel plate, upon the surface of which are cut intersecting corrugations. When the stylus is moved over the paper, it presses the latter down on the corrugations and these pierce the paper along the line of writing. The paper is then placed on a perforated cylinder; ink is forced through the perforations of the cylinder and paper is fed to the cylinder, as in any small printing press. The ink coming through the perforated line on the special paper makes a print on the sheets of paper fed to the cylinder and an indefinite number of copies may be struck off. The paper film is also adapted so that it may be placed on an ordinary typewriter, the ink ribbon of the latter is removed and the stencil is cut by the type bars operated in the ordinary manner. The stencil is then placed on the printing cylinder and copies made in the manner described above for the stencil cut by the stylus.

COPYRIGHT, the exclusive right of property in any intellectual production; the protection afforded by the law for a limited number of years to the originator of any written or printed composition or work of art, or to his heirs and assigns, whereby persons unauthorized are prevented from multiplying and selling copies, or, in case of dramatic works, from representing them on the stage. Such rights were claimed by authors before the introduction of printing. After the invention of the printing press, the right to publish books became the subject of licenses and patents. In Chambers' 'Domestic Annals of Scotland,' under date of 9 Nov. 1699, may be seen a warrant of the Privy Council authorizing George Mossman, stationer in Edinburgh,—

—"to print and sell the works of the learned Mr. George Buchanan, in one volume in folio, or by parts in lesser volumes, and forbidding all others to print, import, or sell the whole or any part of the said Mr. George Buchanan's works in any volume or character, for the space of 19 years."

Similar privileges were granted in England; but all such monopolies were regarded with suspicion by common lawyers. The common law affords a certain measure of protection to works unpublished or published only for a limited purpose. The writer of a letter, for example, transfers his property in it to the receiver; but the receiver has no right to print it for sale or distribution without the writer's consent. The copyright in published works is the creation of statute; the first copyright act was passed in 1709; and by virtue of its provisions authors acquired the sole liberty of printing their books during a term of 14 years from first publication, and, if the author should be living at the end of that time, during a further term of 14 years.

While this act was in force, Thomson sold the copyright of his poems to Millar, a London bookseller. Millar claimed the right to prevent the issue of reprints by Donaldson (of Edinburgh) and others, even after the statutory term had expired, on the ground that an author had, at common law, the sole right of printing his works. Out of this dispute arose the famous cases of Millar *v.* Taylor, and Donaldson *v.* Beckett, which led to a remarkable difference of

opinion among the judges. The House of Lords decided that if any common-law right existed it had been taken away by statute.

At the union with Ireland, the copyright act was extended to that country, and the trade in cheap editions printed in Dublin and secretly imported into Great Britain came to an end. In 1814 the term of copyright was extended to 28 years, and the residue of the author's life if he were living at the end of the term. The impetus given to literature at the beginning of the 19th century, and especially the popularity attained by the works of Scott and Byron, greatly increased the market value of copyright, and ultimately led to further legislation in the interest of authors and publishers. The basis of the existing law is the copyright act of 1842, commonly known as Talfourd's Act, or Lord Mahon's Act. Macaulay's speech in the House of Commons on the second reading of this measure is one of his most successful parliamentary efforts. In Great Britain the term of copyright in a book is 42 years, or the life of the author and seven years, whichever of the two terms is the longer. No copyright can be enjoyed in seditious or immoral publications, or in books first published out of the United Kingdom. Articles contributed to encyclopædias and periodicals and books published in parts or series belong to the proprietor; but he may not publish them separately without the writer's consent, and after 28 years the copyright reverts to the author. Dramas and musical pieces, if first published in book-form, are subject to the same rules as books; but if they are performed in public before appearing in print the author retains the sole right of permitting them to be presented during the term of copyright; and this right is distinct from the copyright he acquires if his drama or piece is published as a book. By an act of 1882 the proprietor of a piece of music, desiring to reserve the right of performance, must give notice to that effect on the cover. Verses may not be taken from a copyright work and set to music for sale, without permission. A novel may be dramatized without the author's permission; but if copies of the drama are published containing passages borrowed in substance from the novel, the author of the adaptation is liable to an action. The right to dramatize can be exercised only with precautions which must greatly restrict it in practice.

Copyright in engravings, maps, etc., is secured by several acts; the term is 28 years. Each plate and print must bear the name of the proprietor. Copyright in paintings, drawings and photographs is secured to the artist during his life and seven years after, by an act of 1862. In 1874 the Canadian Copyright Act enabled a British author to obtain copyright in Canada for 28 years, provided his work be published in the colony. This right is concurrent with and in addition to the rights given by the Imperial Act of 1842.

Prior to the enactment of the first Federal Copyright Law, the various States of the Union had individual copyright laws, having in view the same general purposes, expressed in the Federal Act, that is, to secure to authors or publishers of new books the copyright of such books, and for the encouragement of literature and genius, which laws, generally speaking, followed a resolution of the United States Congress passed 2 May 1783, recommending that the several States secure to the authors and publishers of books and publications the exclusive benefits derived from the sale of such publications for a limited period. By virtue of the authority of the Constitution of the United States 17 Sept. 1787, Art. 1, Sec. 8: «The Congress shall have power to promote the progress of science and useful arts, by securing for limited times to authors and individuals, exclusive right to their respective writings and discoveries.»

The act of 1790 made it possible to secure copyright protection for copies of maps, charts and books, and by an act of 29 April 1902, the benefits of copyright were extended to the arts of designing, engraving and etching, historical and other prints, and there have been many subsequent acts enlarging the scope of the copyright act, and providing for reciprocal protection of copyright matter, with various foreign countries.

Under the authority of the Constitution, as above mentioned, Congress, on 4 March 1909, passed an act to amend and consolidate the previous acts respecting copyright. This act of 1909 was amended 24 Aug. 1912, 2 March 1913, 28 March 1914, which acts are now in force, and upon complying with their various provisions, the exclusive right to print, reprint, publish, copy and vend the copyright work, to translate the copyrighted work into other languages, or dialects, to make other versions of it if it be a literary work, and to dramatize it if it be a non-dramatic work; to convert it into a novel or other non-dramatic work if it be a drama, to arrange it or adapt it if it be a musical work; to complete, execute and finish it if it be a model or a design for a work of art; to deliver or authorize the delivery of the copyrighted work in public for profit, if it be a lecture, sermon, address or similar production; to perform or present the copyrighted work publicly, if it be a drama, or if it be a dramatic work, and not reproduced in copies for sale; to vend any manuscript, or any record whatsoever thereof; to make or to procure the making of any transcription or record thereof by or from which, in whole or in part, it may in any manner or by any method be exhibited, performed, represented, produced or reproduced; and to exhibit, perform, represent, produce or reproduce it in any manner or by any method whatsoever, and to perform the copyright work publicly for profit if it be a musical composition, and for the purpose of public performance for profit; or to print, reprint, publish, copy and vend any arrangement or setting of it or of the melody of it in any system of notation or any form of record, in which the thought of an author may be recorded, and from which it may be read or reproduced.

Books, including composite and cyclopedia works, directories, gazetteers and other compositions, periodicals, newspapers, lectures, sermons, addresses (prepared for oral delivery), dramatic or dramatico-musical compositions, maps, works of art, models or designs for works of art, reproductions of a work of art, drawings or plastic works of a scientific or technical character, photographs, prints and pictorial illustrations, motion picture photoplays, motion pictures other than photoplays, are by acts of 1909, 24 Aug. 1912, 2 March 1913 and 28

March 1914, made the subject matter of copyright protection.

Prior copyright laws required samples of the object upon which copyright protection was sought, to be marked with copyright notice and filed with the Librarian of Congress, before publication. The present Copyright Act of 1909 permits publication of the matter for which copyright is claimed prior to filing with the Register of Copyrights at Washington, D. C. No copyright is valid unless "Notice" of the claim is placed in some manner upon the article or object in which copyright protection is sought. Publication by a person entitled to the benefits of the act, with the copyright notice thereon, "secures" to such person the copyright, and the notice must be affixed to each copy published or offered for sale in the United States by the proprietor, or with his authority, except in case of books seeking "ad interim" protection. The copyright proprietor may obtain registration of his claim to copyright, after publication with the notice of the claim thereon, by filing promptly with the Register of Copyrights two complete copies of the best edition then published, except in the case where the work is by an author who is a citizen or a subject of a foreign state or nation and has published in a foreign country, in which case one complete copy of the best edition then published in the foreign country may be filed. Should the copyright proprietor after publication with notice fail to file the necessary copies with the Register promptly, the Register may, at any time after publication of the work, upon actual notice, require the copies to be deposited, and if the demand is made and not complied with within three months from any part of the United States except an outlying territorial possession of the United States, or within six months from any outlying territorial possession of the United States, or from any foreign country, the proprietor of the copyright will be liable to a fine of $100 and to pay to the Library of Congress twice the amount of the retail price of the best edition of the work, and the copyright shall become void.

Books, including composite and cyclopedic works, directories, gazetteers and other compilations, periodicals, which include newspapers, except the original text of a book of foreign origin, or in foreign language other than English, must be printed from type set within the limits of the United States, or from plates made within the limits of the United States, and if the text is produced by a lithograph process or photoengraving process, the processes must be performed within the limits of the United States, and the printing and binding must be done in the United States. These requirements extend to illustrations in books and illustrations produced by lithographic process or photoengraving process and to separate lithographs or photoengravings, except where the subjects represented are located in a foreign country, and illustrate a scientific work, or reproduce a work of art. These requirements do not apply to works in raised characters for the use of the blind, or to books of foreign origin in other than the English language.

Upon filing application for copyright a fee of $2 is required (Act of 1928) for which the Register makes the entry and issues to the proprietor or claimant a certificate of registration under seal. Where the copyright protection is sought on photographs, and where no certificate is required or demanded by the applicant, a fee of $1.00 is charged.

Copyright protection endures for 28 years from the date of first publication, and a renewal term of 28 years may be had upon application for an extension made within one year prior to the expiration of the original term of copyright, and this right of renewal not only applies to the author himself, but to the widow, widower or children of the author, if the author be deceased, or if such author, widow, widower or children be not living, then to the author's executors, and in the absence of a will, the next of kin to the author is entitled to the renewal and extension of a copyright under the same provisions as to filing application for renewal that characterizes the original application.

If the owner of a copyright has complied with all of the requirements of the law, in obtaining the copyright and has a certificate of registration, he may bring suit for infringement of the copyright, the remedy being in the way of an injunction restraining such infringement and damages which have been suffered by the copyright proprietor due to the infringement, as well as all profits which the infringer shall have made, for such infringement, or in lieu of actual damages and profits, the court may assess such damages as it may think the infringement warrants.

No action for copyright infringement can be maintained until the copyright protection is completed by the insurance of a certificate of registration, and the claimant must have marked or given notice of claim of copyright in the manner prescribed by the law.

The notice of copyright required, if the work be a printed literary, musical or dramatic work, is "Copyright" or abbreviated "Copr." accompanied by the name of the copyright proprietor, and the notice must include also the year in which the copyright was secured by publication, or when it was first published. Certain subject matter of copyright productions, maps, works of art, models or designs for works of art, reproductions of work of art, drawings or plastic works of a scientific character, photographs, prints and pictorial illustrations, may be marked with the letter "C" enclosed within a circle, thus —©— accompanied by the initials, monograms, mark or symbol of the copyright proprietor, provided that on some accessible portion of such copies of the margin, back, permanent base, pedestal or of the substance on which such copy shall be mounted, the name of the copyright proprietor appear, except in cases where a copyright subsisted when the act of 1909 went into force, or 1 July 1909, in which cases the notices prescribed by prior acts are sufficient.

What is called "ad interim" copyright protection may be obtained for a book published abroad in the English language or before publication in this country by deposit of one complete copy of the foreign edition in the copyright office in the United States at Washington, not later than 30 days after its publication abroad, with request for reservation of the name and nationality of the author and of the copyright proprietor and of the date of publication of the book, and such protection will endure for 30 days after the deposit in the American office,

and if an authorized edition of such book is published within the United States within the 30-day period, and the copyright act is otherwise complied with, the protection will be extended to endure for the full term provided by the copyright act.

Copyrights secured under the provisions of the copyright act may be assigned, granted or mortgaged by an instrument in writing signed by the proprietor of the copyright, or may be bequeathed by will, but where an assignment is made, it must be recorded in the copyright office within three months after its execution in the United States or within six months after its execution outside of the limits of the United States, otherwise it will be void as against any subsequent purchaser or mortgagee for valuable consideration without notice, whose assignment has been duly recorded. Under the copyright act, original jurisdiction is given the District Courts of the United States and the District Court of any territory and the Supreme Court of the District of Columbia and the District Courts of Alaska, Hawaii, Porto Rico and the Courts of First Instance of the Philippine Islands. Where the article to be copyrighted comes properly under the head of "Label" or "Print" which comprises artistic matter, for use upon merchandise or for advertising merchandise, it is registrable in the United States Patent Office by complying with certain rules and regulations made by the Commissioner of Patents, but the label or print must have upon it, when first published, the copyright notice as prescribed by the copyright act. The authority for this Patent Office registration is contained in the act of 18 June 1874, relating to the registration of prints and labels, and section 3 of the act is not repealed by the copyright act of 4 March 1909, or any acts in the interim between 18 June 1874 and 1909, and it provides that no prints or labels designed for use on any other articles of manufacture shall be entered under the copyright law, but may be registered in the Patent Office.

Until 1891, copyright could be acquired only by a citizen of, or permanent residence in, the United States. British and other authors had much reason to complain of this state of the law, and American authors were injured by having to compete with cheap, unauthorized reprints of foreign works, but this condition no longer exists, and there is in most instances a very good understanding between the United States and foreign nations in copyright matters.

Foreign Works.—There was at one time an understanding that the American publisher who first placed a British work on the market obtained copyright by courtesy; and considerable sums were paid for "advance sheets" in order to obtain this advantage, but the "courtesy of the trade" came to be disregarded. In December 1887, the convention of Bern brought nearly all the states of Europe into copyright relations with one another. This was the most important step ever taken in the history of the world's literary dealings, for it secured an almost universal recognition of the rights of authors.

The rights of citizens or subjects of foreign nations to copyright in the United States may be extended by presidential proclamations, and now Americans can secure copyright in all foreign countries with which we have reciprocal copyright arrangements, and in consequence a citizen or subject of a foreign state or nation may obtain copyright protection upon copyrightable matter when such alien is domiciled within the United States and his work is published for the first time in the United States, or, as just suggested, when the foreign state or nation of which such author or proprietor is a citizen or a subject grants, either by treaty, convention, agreement or law, to citizens of the United States the benefits of copyright on substantially the same basis as to its own citizens, or copyright protection substantially equal to the protection secured to such foreign author under the United States act, by treaty, or when such foreign state or nation is a party to an international agreement which provides for reciprocity in the granting of copyright, by the term of which agreement the United States may, at its pleasure, become a party thereto.

Presidential proclamations have been issued upon this basis permitting citizens or subjects of the following foreign states and nations to obtain copyright protection in the United States: Canada, Great Britain and British possessions, France, Belgium, Germany, Luxemburg, Sweden, Switzerland, Italy, Greece, Tunis, Hungary, Denmark, Portugal, Spain, Netherlands and possessions, Norway, Japan, China, Austria, Mexico, Cuba, Dominican Republic, Haiti, the Central American republics, Panama, all the South American republics except Colombia and Venezuela, Czechoslovakia, Poland, Finland, Rumania, Siam and New Zealand. An American citizen secures copyright in Great Britain by entering the title at Stationers' Hall, London, the fee for which is five shillings sterling, and five shillings additional if a certified copy of entry is required. The work must be published in Great Britain or in her dominions simultaneously with its publication in the United States, and five copies of the publication are required, one for the British Museum and four on demand of the Company of Stationers for four other libraries. Copyright may be secured in France by a foreigner by depositing two copies of the publication at the Ministry of the Interior at Paris. No fee or entry title is required. To secure copyright in Belgium a foreigner may register his work at the Department of Agriculture, Industry and Public Works at Brussels. The term is the life of the author and 50 years after death except in cases of foreign authors, then the term is limited not to exceed that granted in the home country. In Switzerland register of title at the Department of Commerce and Industry at Bern is optional, not obligatory; fee two francs. If registered, deposit of one copy is required. The term is the life of the author and 30 years after death. Works published by corporate body 30 years from publication. Photographs five years from registration. Copyright in Canada is to be registered with the Minister of Agriculture at Ottawa; fee $1 for registry and 50 cents for certificate, and the work must be published in Canada and two copies deposited. The term is 28 years with renewal of 14 years or 42 years in all.

In Greece the period during which an author can hold a copyright is restricted to 15 years. The Swiss grant copyright during the life of the author or his heirs during 30 years from the date of publication of his work. In Brazil, the term of copyright is 50 years from publica-

tion. In Venezuela the copyright is perpetual. In Holland the copyright lasts 50 years after publication. In Hungary and Portugal, copyright endures for the life of the author and 50 years after his death. In Germany and Austria copyright endures during the life of the author and during 30 years after his death. The duration of copyright in Italy is regulated in a peculiar manner. It endures for the life of the author and 40 years after his death, or for 80 years after the publication of the work, the term of years being divided into two periods of 40 years each. If the author dies within the first period of 40 years the remainder of the term is enjoyed by his heirs or assigns. The second period of 40 years begins at the death of the author, if he has died after the first period of 40 years has elapsed; or if he has died before them, at the end of the first period of 40 years. During the second period any one is at liberty to republish the work on payment to the owner of the copyright of a royalty of 5 per cent on the price, which must be marked on the book. France, Norway, Sweden and Denmark accord a copyright during the life of the author and 50 years after his death. Russia not only gives copyrights for life and 50 years after death, but also for 10 additional years if an edition of the work is published within five years from the end of the first copyright term. The law of Spain accords a copyright during the life of the author and for 80 years thereafter. In Mexico copyright is perpetual.

Revised by TITIAN W. JOHNSON, *of the Washington Bar.*

COPYRIGHT, Canadian. The first Canadian copyright act was passed by the legislature of lower Canada on 25 Feb. 1832 (2 William IV, c. 53). This act was repealed and replaced by an act of the province of Canada relating to copyright, passed in 1841 (4–5 Vict., c. 61), allowing copyright to any resident of the province on depositing with the Provincial Registrar a copy of the work and printing in the work a notice of the entry. In 1842 an Imperial Act (5–6 Vict., c. 45) gave to a work first published in the United Kingdom protection throughout the empire. As at the time the United States had no agreement with the United Kingdom as to copyrights, United States publishers reprinted in cheap editions books copyrighted in the United Kingdom, and many such books naturally found their way into Canada. By the Foreign Reprints Act of 1847 (10–11 Vict., c. 95), the Imperial Government made it possible for Canadians to secure these cheap editions on making provisions safeguarding the rights of the British authors. This was done by Canada in 1850 by an "Act to Impose a Duty on Foreign Reprints of British Copyright Works" (13–14 Vict., c. 6), and the duty so imposed was continued by the first Dominion Act of 1868 (31 Vict., cc. 54 and 56), the latter act authorizing the Governor in Council to impose a duty not exceeding 20 per cent ad valorem on such reprints and to distribute the proceeds among the owners of the copyrights.

By the British North America Act, exclusive legislative authority in matters of copyright was assigned to the Dominion Parliament. In 1875 an act was passed (38 Vict., c. 88) allowing a copyright for 28 years to persons domiciled in Canada or in any British possession, or who, being citizens of any country having an international copyright agreement with the United Kingdom, had registered their claim and complied with the usual conditions.

In 1886 an International Copyright Act (49–50 Vict., c. 33) was passed by the Imperial Parliament, giving to Queen Victoria the right to accede to the Berne Convention. As Canada thus became a member of the Berne Convention, with the privilege of withdrawal, books published in Canada by Canadians secured the same privileges as books published first in the United Kingdom, an author of any country subscribing to the convention obtaining in any other country in the union the same rights as an author of that country. An Imperial Act of 1911 set forth general copyright regulations for the empire.

The Copyright Act of 1921 (as amended by the Act of 1923), which became effective on 1 Jan. 1924, sets out in Section 4 the qualifications for a copyright, and in Section 5 its duration. "Copyright shall subsist in Canada . . . in every original literary, dramatic, musical and artistic work, if the author was at the date of the making of the work a British subject, a citizen or subject of a foreign country which has adhered to the (Berne) Convention and the Additional Protocol . . . or a resident within His Majesty's Dominions. The term for which the copyright shall subsist shall, except as otherwise expressly provided by this Act, be the life of the author and a period of fifty years after his death." Section 13 provides that if at any time the owner of the copyright fails to print the book in Canada and satisfy the reasonable Canadian demand therefor, anyone may apply for a license to the minister administering the act, who may, if the owner fails to print an edition, grant a license to the applicant on the latter paying a royalty to the owner.

Copyright protection is extended to records, perforated rolls, cinematographic films or other contrivances by means of which a work may be mechanically performed. The intention of the act is to enable Canadian authors to obtain full copyright protection throughout all parts of His Majesty's Dominions, foreign countries of the Copyright Union and the United States of America, as well as in Canada.

This act, as amended by Chapter 10 of 1923, restricting the "licensing sections" to citizens of Canada and subjects or citizens of countries which do not belong to the International Copyright Union, came into force on 1 Jan. 1924, and repealed all imperial copyright acts as far as operative in Canada and all existing Canadian copyright statutes.

Formerly difficulties arose from the importation into Canada from the United States of reprints of British works sold at low prices, and which it had been practically almost impossible to restrain. When these were so imported by American publishers under agreement with the British author, the Canadian printer and publisher saw themselves constantly deprived of business which they considered should be theirs, as no reciprocity was permitted them by the

United States. The amended act remedies this defect.

WILLIAM DOUW LIGHTHALL,
Revised from The Canada Year Book.

COQUELIN, kōk-lăń, **Benoit Constant,** French actor: b. Boulogne, 23 Jan. 1841; d. France, 26 Jan. 1909. He is known as Coquelin Ainé, to distinguish him from his younger brother, Coquelin Cadet. He early gave promise of great dramatic ability. He was admitted to the Paris Conservatoire in 1859, the following year took the second prize for comedy, and made his début on the stage of the Théâtre Français, 7 Dec. 1860, as Gros-René in 'Le dépit amoureux.' Later he appeared with great success in 'Le Mariage de Figaro,' 'Le malade imaginaire,' 'Le misanthrope,' 'Le barbier de Seville,' and other pieces in the classical repertoire. His versatility was considered remarkable, as he was no less effective in modern plays, and he speedily became a popular favorite. He was elected a sociétaire in the Théâtre Français in 1864, but in 1886 he retired and made an extensive tour abroad. He made his first visit to America in 1888. About the end of 1889 he rejoined the Théâtre Français company as a salaried member and remained with that organization until 1892. In 1893–94 he again appeared in the United States. Upon his return to Paris he formed an engagement with the Renaissance Theatre, which led to a lawsuit with the Comédie Française in which Coquelin was condemned to pay damages. In 1900–01 he visited America again, in company with Sarah Bernhardt (q.v.), to whose Duke de Reichstadt he played Flambeau in Rostand's 'L'Aiglon.' Among the many characters created by M. Coquelin in later years are those of Labussière in 'Thermidor,' Cyrano de Bergerac in Rostand's play of that name, and Napoleon in 'More than Queen.' He was without a rival among his contemporaries. His versatility and mastery of technique were unequalled. He entered into the soul of the part he was playing and his simplicity and directness made a great appeal to his audience. Together with his high rank as a comedian M. Coquelin became celebrated as an author and lecturer, among his publications being 'L'Art et le comédien' (1880), which has been translated into German and into English (as 'The Actor and his Art'); 'Les comédiens par un comédien' (1882), and 'L'Arnolphe de Molière' (1882), and in collaboration with his brother, 'L'Art de dire le monologue' (1884). Consult De Amicis, Edmondo, "L'attore Coquelin" (in 'Ritratti letterari', 3d ed., Milan 1881); and Zabel, E., "Coquelin im Berliner Schauspielhause" in 'Zur modernen Dramaturgie,' Vol. III, Oldenburg 1903).

COQUELIN, Ernest Alexandre Honoré, French actor; brother of Benoit Coquelin: b. Boulogne, 16 May 1848; d. Suresnes, 8 Feb. 1909. He was educated at the high school of his native city and was for a time in the employ of the Northern Railway, but following in the footsteps of his brother went to Paris in 1864 and entered the Conservatoire, to make a career upon the stage. He was graduated three years later with the first prize in comedy and made his début at the Odéon. In 1868 he became associated with his brother at the Théâtre Français, and continued there until 1875, playing in all the well-known classical comedies. He took an engagement at the Variétés in 1875, but returned to the Théâtre Français in the following year, shortly after becoming a member of the company. He created the parts in 'Le sphinx,' 'L'Ami Fritz,' 'Les corbeaux,' 'Denise' and 'L'Héritière.' M. Coquelin, Cadet, as he was called, to distinguish him from his greater brother, was the author of numerous monologues, to the success of which he owed most of his reputation, and his rendering of them gained him great popularity in Paris. Under the nom-de-plume of Pirouette he published 'Le livre des convalescents' (1880); 'Le monologue moderne' (1881); 'Fariboles' (1882); 'Le rire' (1887); 'Pirouettes' (1888), etc.

COQUELIN, Jean, French actor: b. 1 Dec. 1865. He is a son of B. C. Coquelin (q.v.), and adopting his father's rôles appeared at the Comédie Française for the first time, 20 Nov. 1890. In 1897 at the Porte-Saint-Martin he created the rôle of Ragueneau in 'Cyrano de Bergerac.' Other famous rôles were Lubin in 'Thermidor'; Verdelet in 'Le gendre de M. Poirier' and Talleyrand in 'Plus que reine' (1899).

COQUEREL, kō'krĕl', **Athanase Josué,** French Protestant clergyman: b. Amsterdam, 16 June 1820; d. Fismes, Marne, France, 24 July 1875. He was a son of A. L. C. Coquerel, and was the author of 'Jean Calas et sa famille' (1858) 'Libres études' (1867); 'Des Beaux-Arts en Italie' (1857), etc. He was widely known as an eloquent preacher, and was long a leader of the liberal Protestant party in France. Consult Stroehlin, 'Athanase Coquerel, fils' (2 vols., Paris 1886).

COQUILLA NUT (Sp. *coquillo,* "little coconut"), the seed of the piassava or piassaba palm, *Attalea funifera,* one of the coconut group, a native of Brazil. The nuts are three or four inches long, oval, of a rich brown color and very hard, and are used in turnery for making umbrella handles, etc. They are known as vegetable ivory. Under the name tagua nut, of the ivory-palm (*Phytelephas macrocarpa*) of Panama, vegetable ivory is exported, chiefly from Ecuador, Colombia and Panama.

COQUILLE, Oreg., city, Coos County seat; alt. 60 feet; on the Southern Pacific R.R.; 140m. SW. of Eugene. Pop. (1940) 3,327.

COQUIMBO, kō-kēm'bō, Chile, a province situated in the northern part of the republic, between the provinces of Atacama and Aconcagua. Its area, since the 1927 reformation of provinces, is 15,043 square miles. Pop. 172,254. The principal towns are La Serena, the capital (pop. 15,240); Coquimbo, the principal seaport of the province, which is one-half hour by rail from the capital, and has 12,106 inhabitants; Ovalle (5,500); Elqui (2,500); Illapel and Combarbalá. Gold, silver, copper, iron, quicksilver, lapis lazuli and lime are found. There are four large copper-smelting establishments, and several others for silver and gold ore. Natural pasturage is abundant. Agricultural products in excess of the needs of the province are exported in considerable quantities. Vineyards are located near the mountain range and wines and brandies are produced. Two lines of railway belonging to the government and one

belonging to a private company are in operation; the total length of the government lines being about 200 miles. There are telegraph and telephone services throughout the province, and at La Serena and Coquimbo are offices of the submarine cable. There is also a wireless station at Coquimbo. Pop. (est. 1929) 199,000.

COQUIMBO, Chile, a seaport. See COQUIMBO, a province.

COQUIMBO. See BURROWING OWL.

COQUINA, kō-kē'na, a porous rock found in Florida, where it is used for building purposes. It is composed of the broken shells of sea animals and coral cemented together.

COR ANGLAIS, kôr än-glā' (Fr. "English horn"), a wind instrument of the reed kind, similar to the oboe, and possessing a compass of like extent but of lower pitch. Its compass is from E in the bass to B flat above the treble staff. In Bach's works it appears as the Oboe di Caccia. Its effective wailing tone has caused it to be used by modern operatic composers.

CORACIIFORMES, an order of birds comprising a somewhat miscellaneous group, formerly designated as "picarian." Nearly all are arboreal, and are characterized by comparatively short and weak legs, and by usually nesting in holes. They include the rollers, motmots, todies, kingfishers, bee-eaters, hornbills, etc. (*Coraciæ*); the owls (*Striges*); the nightjars (*Caprimulgi*); the swifts (*Cypseli*); the mouse-birds (*Colii*); the trogons (*Trogones*) and the woodpeckers (*Pici*). See ORNITHOLOGY.

CORACLE, kŏr'ą-kl, or **CURRACH** (Ir. *curach;* W. *corwe*), a kind of ancient boat, constructed with a frame or body of wicker-work, and still in use among Welsh fishermen and on the Irish lakes. It is covered by skins, oil-cloth, etc., which are removed when out of use. It is of an oval form, and generally contains but one man, who, on reaching the shore, shoulders his coracle, and deposits it in a place of safety, or carries it perhaps where he may again make use of it. Cæsar (De Bello Civili, i, 54) describes coracles which he made after the British model for use in Spain. The coracle or currach is mentioned in the lives of Saint Patrick, Saint Columba and in accounts of travels made by Scots and Picts.

CORACOID, kŏr'ą-koid (Gr. "crow-shaped," that is, like a crow's bill), an important paired-bone in the breast-girdle, forming, along with the scapula, the articulation for the forelimb, and always lying ventrally. In the lower fishes the entire girdle is cartilaginous. In the bony fishes distinct coracoids first appear. They are well seen in *Amphibia* and in all reptiles except snakes, and are very large and strong in birds; but they become mere processes of the scapula in mammals. They very often exhibit a special anterior portion known as the precoracoid.

CORAL AND CORAL ISLANDS, the solid support or skeleton of the coral polyps. (See POLYPS). It was formerly supposed that the coral was a calcified portion of the soft parts of the animal, but this has been disproved. Recently Bourne has proved by examination that the skeleton is formed as a secretion by certain cells and that there is no deposition of crystalline carbonate of lime in the actual cells. The calcareous septa or partitions are deposited by the soft septa of the animal in the radial chambers. The coral particles begin to be deposited in the embryo polyp before it becomes fixed to the bottom. In the very young polyp of the Mediterranean Astroides, as soon as it becomes stationary 12 calcareous partitions are deposited, and these enlarge and finally become jointed to the external walls (theca) of the coral, forming a groundwork or pedestal, on which the young polyp rests, as if on a limestone foundation. If isolated needles or rods of lime are distributed beneath the outer layers of the polyp-stock, the latter becomes horny or leathery and more or less flexible, as in the alcyonarian polyps. The entire skeletal mass is called the corallium or coral-stock. In the common red coral (*Corallium rubrum*) of the Mediterranean, the solid unjointed coral-stock has a thin cortical layer of spicules in which the polyps are retractile.

Coral-like masses, encrusting reefs, are also formed by the animals of the hydroid millepore, which may be distinguished by the multitude of minute cells or openings, much smaller than those of any genuine coral polyp. See MILLEPORE.

The simpler, most primitive corals, are cup-shaped, forming a single calicle or corallite, containing but one polyp, as in the early Paleozoic cup-corals, and the existing species of Flabellum, *Caryophyllia* and *Deltocyathus,* which live buried in the mud in deep cold water in all seas, from Greenland to the tropics.

Microscopic Structure of Coral.—There are two kinds. In the aporose or poreless corals such as Flabellum, Astræa and the like, the coral-stock is throughout its mass solid and stony. In the perforate kinds, such as Madrepora, all parts of the corallium, including the connecting cœnenchym, or common calcareous stock or stem, has a structure like a meshwork, consisting of delicate rods of carbonate of lime so united as to leave interstices, which in the living coral are traversed by a network of interlacing tubes, representing the cœnosarc.

Rate of Growth of Corals.—Little is known regarding the rapidity of growth in corals. A specimen of *Mæandrina labyrinthica,* measuring a foot in diameter and four inches thick in the most convex part, was taken from a block of concrete at Fort Jefferson, Tortugas, which had been in the water only 20 years. Hunt calculated that the average growth of a *Mæandrina* observed by him at Key West was half an inch a year. Verrill states that a *Madrepora* found growing on the wreck of the ship *Severn* grew to a height of 16 feet in 64 years, or at the rate of three inches a year. See POLYP.

Coral Islands.—The reef-building corals are the *Madrepora* and *Mæandrina,* the latter dome shaped and massive. They are confined to waters in which through the coldest winter months the temperature does not fall below 68° F., though usually the water is warmer than this, the mean annual temperature of the north Pacific being about 73.5° F., and of the south Pacific 70° F. Coral reefs are abundant in the West Indies and occur on the coast of Brazil as far south as Cape Frio, but still more so on the central Pacific. None occur on the western coast of Europe and Africa and the two Americas. In depth reef-building species do not occur below 15 to 20 fathoms. Coral reefs are

divided into fringing, barrier and circular reefs, or atolls. Fringing reefs encrust the shores on which they grow. Barrier reefs have a lagoon between the reef and the main land. A fringing reef may ultimately become a barrier reef either by a sinking of the land and the successive upbuilding of the seaward face of the reef, or by gradual dying of the coral polyps next to the land where they do not get enough fresh water and food, the stony skeleton being redissolved while the outer part of the reef continues to grow. Atolls are roughly circular, with a central lagoon, with or without central islands. Contrary to the views of Darwin and Dana, it has been found by A. Agassiz that modern coral reefs form as a rule but a thin crust, those of Florida not more than from 50 to 75 feet in thickness; yet Tertiary reefs and those geologically older may be much thicker. According to Darwin and Dana atolls were supposed to have been formed on submarine banks over a subsiding sea-bottom, first starting as a fringing reef about an island or slightly submerged peak. After they had grown to the surface, the inner face of the reef could not get food, and ceased to grow. As the island or peak gradually sank, the outer face of the reef grew up in a ring. Owing to the observation of Semper, Agassiz and others, it is now evident that atolls may be deposited under any conditions, whether the sea-bottom be stationary, rising or subsiding. We will, however, have to hold on to the Darwin subsidence theory to account for coral reefs over about 100 feet in thickness, since corals do not grow at greater depths than this. From his prolonged explorations in the West Indies and the Pacific Ocean, A. Agassiz concludes that the barrier reefs of Fiji, the Hawaiian Islands and the West Indies usually flank volcanic islands and are underlaid by volcanic rocks. Those of New Caledonia, Australia, Florida, Honduras and the Bahamas are underlaid by outliers of the adjoining land-masses, which crop out as islands and islets in the outer edge of the barrier reefs. Some of the barrier reefs of the Society, Fiji and of the Carolines, show that the wide and deep lagoons, separating them from the main islands, have been formed by erosion, from a broad, fringing reef-flat, as explained above.

The reef-flats and outer reefs flanking elevated islands are partly barrier and partly fringing reefs. We may, says Agassiz, trace the passage of elevated plateaus like Guam, Tonga and some of the Fiji islands, which are partly volcanic and partly limestone, to atolls where only a small islet or a larger island of either limestone or volcanic rock is left to indicate its origin. Atolls also may be formed upon the denuded rim of a submerged volcanic crater, as in certain of the Fijis (Totoya and Trombia), and as in some of the volcanoes east of Tonga.

As to the origin of atolls by subsidence, we really have few data to support the Darwinian theory. Agassiz claims that throughout the Pacific, Indian Ocean and West Indies «the most positive evidence exists of a moderate, recent elevation of the coral reefs.» This is shown by the ridges, pinnacles and undermined masses of modern or Tertiary limestones formed recently beneath the sea, but now above sea-level, proving very recent uplift. The existence of honeycombed pinnacles of limestone within the lagoons of atolls, as shoals, islands or islets, shows the extent of the solvent action of the sea upon land areas having formerly a greater extension than at the present day. The Maldivian plateau with its thousands of small atolls, rings or lagoon reefs, rising from a depth varying from 20 to 30 fathoms, is overwhelming testimony, says Agassiz, that atolls may rise from a plateau of suitable depth, wherever and however it may have been formed, and whatever may be its geological structure. In the regions examined by Agassiz the modern reef-rock is of every moderate thickness, being within the limit of depth at which reef-builders begin to grow and within which the land rims of atolls or of barrier reefs are affected by mechanical causes.

Why no coral reefs exist on the western coasts of the two Americas, and their absence at other points, is explained by Agassiz as due to the steepness of their shores and to the absence or to the crumbling nature of their submarine foundations or platforms. Coral reefs also cannot grow off the steep cliff-surfaces of elevated, coraliferous limestone islands.

The proof of the supposed great thickness of coral reefs, to account for which Darwin invoked subsidence, will be ascertained by boring. Thus far the evidence tends to show that the coral beds are not continuous. At Honolulu they contained several beds of volcanic ash, etc. In the Fiji Islands, shell limestones were interstratified with coral rock. The great areas of subsidences postulated by Darwin and by Dana have been shown to be areas of elevation. The deepest depressions or «deeps» in the Pacific, judging by the *Challenger* maps, are in regions where there are no coral reefs or atolls.

Bibliography.—The classic works are J. D. Dana's folio in the reports of the Wilkes Exploring Expedition, and his 'Corals and Coral Islands' (revised edition, New York 1890); and Darwin's 'Structure and Distribution of Coral Islands' (London, 3d ed., with notes by Bonney, New York 1899). Murray's papers in the 'Proceedings' of the Royal Society of Edinburgh, Vols. X and XVII (1880, 1891), are important. Alexander Agassiz contributed valuably with his 'Visit to the Great Barrier Reef of Australia' (Cambridge, Mass., 1898). For fossil corals consult Zittell-Eastman, 'Text-book of Palæontology' (London 1900). Consult also W. M. Davis's 'Coral Reef Problem' (American Geographical Society, 1928); J. S. Gardiner's 'Coral Reefs and Atolls' (New York 1931); C. M. Yonge's 'Great Barrier Reef' (New York 1931). See BARRIER REEF, THE GREAT.

CORAL FISHES, a name given to several fishes of different genera belonging to the *Chætodonitdæ.* They are found in aall tropical seas, especially about coral reefs, and are all brilliantly colored. The most important is the *Holacanthus imperator,* the «emperor of Japan,» which measures about 15 inches in length and is the most esteemed of all the Indo-Pacific fishes.

CORAL GABLES, Fla., city of Dade County, alt. 11 feet, on the Florida East Coast and the Seaboard Air Line railways, adjoining Miami; connected with East Coast Canal by the Coral Gables Canal. A residential and winter re-

sort city, it has a public library and a community house with an auditorium, and is the seat of the University of Miami. Just outside the city is the Tropical Park Race Track. Coral Gables has a commission government, with a city manager. Pop. (1940) 8,294.

CORAL ISLANDS. See CORAL.

CORAL SEA, part of the Pacific Ocean northeast of Australia and between it and the New Hebrides. It extends between the parallel of 25° S. and Torres Strait. The numerous coral islands fringing the northeast of Australia and other islands washed by this sea give it its name. In 1874 the *Challenger,* when making soundings in these waters, found the Coral Sea, in some places, to be 14,700 feet deep. The coral growths of the great barrier reef lie along its western boundary.

CORAL SNAKE, a small venomous colubroid snake of the same family (*Elapidæ*) as the cobra. The typical genus (*Elaps*) is a strictly American one. The usual color is rich red with black and yellow transverse bands, making these among the most brilliantly colored of snakes. Owing to the position of the poison-fangs and the small size of the mouth they are, although venomous, usually unable to injure man. One species, the harlequin or bead snake (*E. fulvius*), occurs in the southern United States as far north at least as Virginia. It is a beautiful snake, about two feet or more long, and is less feared than it should be. Most of the remaining species, including the typical *E. corallinus,* are confined to tropical South America and the West Indies.

CORAL TREE, leguminous plants of the genus *Erythrina,* which has about 50 species. They are shrubs or trees with trifoliolate leaves and racemes of scarlet flowers. The long pods enclose bright red seeds. They are mostly tropical, natives of America, Africa and India. One species (*E. herbacea*) is common throughout the southeastern United States, and two more are found in Florida. The plants are much cultivated in greenhouses. An Indian species (*E. indica*) is said to have been stolen by Krishna, the Hindu deity, from the gardens of paradise. This is a spiny plant, and is planted for hedges. This species and *E. caffra* (the kaffir-boom of Africa) furnish soft light wood valuable for industrial purposes.

CORALLINE, kŏr'ą-lĭn, a term popularly applied to sea-weeds with rigid calcareous fronds and also to certain of the zoophytes. The coralline algæ are mostly purple and gradually grow paler and whiter as the season advances. Their habitat is commonly pebbly rocks, to which they cling fast. *Corallina officinalis* has been employed as a vermifuge.

CORALLINE, or **PÆONINE,** an orange-red color prepared by the action of ammonia, at about 300° F., upon rosolic acid, or upon the washed residue of the action of a mixture of sulphuric, oxalic and carbolic acids. It differs from magenta in both its tint and its permanency, not being affected by light or by alkalis; but, on the other hand, fabrics dyed with it are readily turned yellow by acids. It is insoluble in water, but dissolves in alcohol with a very rich color. This solution, mixed with soda and a large quantity of water, and tartaric acid added, is employed for dyeing silk. It is also printed upon cotton by means of albumen. The use of this dye has been much restricted on account of its alleged poisonous properties.

CORAM, Thomas, English philanthropist: b. Lyme Regis, Dorsetshire, about 1668; d. London, 29 March 1751. He was bred a seaman and rose to be a merchant captain. In 1694 he settled in Taunton, Mass., and engaged in benevolent work of various kinds. A few years after he returned to sea, and settled in London, after suffering shipwreck off Cuxhaven in 1719. In London he interested himself in the settlement of Georgia, and in planting English artisans in Nova Scotia; but soon began his long agitation for the foundation of a foundling hospital in London, which was at length opened in 1740. Coram's portrait was painted by Hogarth, a warm patron of his scheme. More thoughtful for others than for himself, Coram fell into poverty, from which he was relieved in 1745 by an annuity contributed by his friends.

CORANACH, kŏr'ą-năk, or **CORONACH,** a dirge or lamentation for the dead formerly customary among the Celts of Scotland and Ireland. The coranach is commonly known in Ireland as the caóine (Br. keen), a song of mourning for the dead. This funeral song, or dirge, was usually sung by professionals who had power to improvise and who told of the pedigree, worth, deeds and death of the deceased. In Scotland the weird, mournful notes of the bagpipes added sadness. The custom of having the caóine or coranach at wakes and funerals has fallen into disuse in both Ireland and Scotland. Frequent mention of the custom may be found in the writings of Sir Walter Scott, Lover, Davis and other writers. Consult Crocker, Crofton, 'Researches in the South of Ireland'; Jamieson, 'Etymological Dictionary of the Scottish Language' (Paisley 1879).

CORANDAGOS, IS-LANDS, kō-rän-dä'gōs, Philippines, group of islands lying off the northeastern coast of Palawan. The group consists of two islands, Corandagas and Dalangamen, and three islets. Pop. about 300.

CORAOPOLIS, Pa., borough of Allegheny County; alt. 730 feet; on the Ohio River; 11m. NW. of Pittsburgh; on the Pittsburgh and Lake Erie Railroad; in a coal, oil and gas district; with glass works and metal plants. Pop. (1940) 11,086.

CORATO, kō-rä'tō, Italy, city in Apulia, about 50 miles southeast of Foggia. The modern city is of little importance, the chief industries being cattle raising and the manufacture of leather and tartar. Near the city are the ruins of the famous Castel del Monte, built by Frederick II, which is one of the most beautiful of the architectural remains of the Middle Ages in Italy. The general plan is a vast octagon, with eight hexagonal towers. The windows are pointed and round arched, and the vaulted halls are supported by triple shafts of marble. It is the chief attraction of the city. Pop. 45,307.

CORBAN, kôr' ban, a term used by the Jews to signify a thing given to the Deity. (Lev. ii, 4, 12, 13, etc.) Such an object was sacred and set apart from profane use. It often was used to designate an oblation to God and has reference to a Talmudic formula, by which, under pretense of dedicating a thing to God, a person might prohibit the use of it by

another person. Thus a son might declare his property as corban and avoid the obligation of using it for the support or need of a parent. This interpretation was rebuked (Matt. xv, 5 and Mark vii, 11), and also by some of the more tolerant and wiser rabbis.

CORBEIL, kôr'bā'yė, France, a town in northern France, in the department of Seine-et-Oise, at the junction of the Essenne with the Seine, 18 miles south-southeast of Paris. It has various manufactures, chiefly of paper, clocks, cotton and linen; and there are large grain-mills and a copper-foundry in the town. Pop. 11,230.

CORBEL, kôr'bĕl, in architecture, a piece of stone, wood or iron projecting from the vertical face of a wall, to support some superincumbent object. Corbels are of a great variety of forms, and are ornamented in many ways. They are of frequent occurrence in pointed architecture, forming the supports of the beams of floors and of roofs, the machicolations of a fortress, the labels of doors and windows, etc. A cornice supported by a series of corbels is styled a corbel table. Similar contrivances are the bracket and cantilever (qq.v.).

CORBETT, Julian Stafford, English lawyer and author: b. Surrey, 12 Nov. 1854; d. 21 Sept. 1922. He was educated at Marlborough and Trinity College, Cambridge, and was called to the bar in the Middle Temple in 1877. He practised his profession until 1882 and thereafter gave his attention to literary pursuits. He published 'A Business in Great Waters'; lives of Monk and Drake in 'English Men of Action' series; 'Drake and the Tudor Navy'; 'The Successors of Drake'; 'England in the Mediterranean'; 'England in the Seven Years' War'; 'The Campaign of Trafalgar'; 'Some Principles of Maritime Strategy'; 'The Spencer Papers.'

CORBETT, Lee Cleveland, American horticulturist: b. Watkins, N. Y., 21 Oct. 1867. He was educated at Cornell University, where from 1891 to 1893 he was assistant horticulturist. He was professor of horticulture and forestry at the South Dakota Agricultural College in 1893–95 and at the West Virginia University from 1895 to 1901; in the U. S. Department of Agriculture, becoming principal horticulturist in 1929. His publications include 'Garden Farming' (1913); 'Intensive Agriculture' (1913); and the following experiment station bulletins: 'Pruning' (1903); 'Cranberry Culture' (1903); 'The School Garden' (1904); 'Tomatoes' (1905); 'Raspberries' (1905); 'Beans' (1907); 'Cabbages' (1911); 'Ice Houses' (1911); 'Tomato Growing as Club Work in the North and West' (1913); also articles in the annual.

CORBIE STEPS, CORBEL STEPS, or CROW STEPS, steps into which the sides of gables from the eaves to the apex are broken. They form a common feature in Scottish architecture, into which they were probably introduced from France. They are also to be seen in many old houses in Holland, Flanders and Germany, where they are even more general, especially in the north.

CORBIN, Caroline Fairfield, American writer: b. Pomfret, Conn., 9 Nov. 1835; married C. K. Corbin of Chicago, 1861. She published 'Our Bible Class and the Good that Came of It' (1860); 'Rebecca, or Woman's Secret' (1866); 'His Marriage Vow' (1874); 'Belle and the Boys' (1879); 'Letters from a Chimney Corner' (1886); 'A Woman's Philosophy of Love' (1892). Deceased.

CORBIN, Henry Clark, American soldier: b. Clermont County, Ohio, 15 Sept. 1842; d. New York, 8 Sept. 1909. He studied law, and entered the Union army as second lieutenant in the 83d Ohio Volunteer Infantry, 28 July 1862; but before the organization was completed he was assigned to the 79th Ohio Volunteer Infantry, serving therein as second and first lieutenant, respectively, until 14 Nov. 1863, when he was appointed major of the 14th U. S. Colored Infantry. In the following year (4 March 1864) he was promoted to lieutenant-colonel, and 23 Sept. 1865, made colonel of the 14th United States Colored Infantry. He was honorably discharged from the volunteer service 26 March 1866, with the brevet of brigadier-general, which honorary rank was bestowed upon him in recognition of meritorious services. In 1866, upon the muster-out of the volunteer army, and upon the recommendation of his military commanders, he was commissioned (11 May 1866) second lieutenant in the regular army. He was appointed to a captaincy of the line 31 Dec. 1866, and from that year to 1876 he was continually in command of his company on the Western frontier in campaigns against hostile Indians.

He was appointed to the adjutant-general's department 16 June 1880, and served therein nine years in the grade of major, seven years in the grade of lieutenant-colonel and two years in the grade of colonel; and was, when appointed brigadier-general and adjutant-general of the army (25 Feb. 1898), the senior in the corps; having served on the staffs of Generals Hunt, Schofield, Terry, Crook, Miles (with whom he participated in the Sioux Indian campaign), McCook, Ruger, Merritt, and in 1891 conducted a successful campaign against the Moqui Indians in Arizona Territory.

During the Spanish-American War, General Corbin was brought into close relations with President McKinley and was by him consulted upon all questions of policy relating to military affairs; and in addition to his duties as adjutant-general of the army he superintended the organization of 250,000 soldiers, and within six months the muster-out of 100,000. Subsequently 35,000 additional volunteer forces were mustered, equipped and made effective for the Philippine service, and they in turn disbanded — the regular army having been increased during this period to three-fold its former strength. In recognition of his services and of the part which he took in the war, the Congress of the United States conferred upon him the rank of major-general and adjutant-general in the army of the United States. He was in command of the Division of the Philippines in 1904–06, when he was made a lieutenant-general, and retired.

CORBIN, John, American dramatic critic writer, son of Caroline F. Corbin (q.v.): b. Chicago, Ill., 2 May 1870. He was educated at Harvard University, and at Balliol College, Oxford. From 1897 to 1900 he was assistant editor of *Harper's Magazine;* was member of the editorial staff of the Encyclopedia Britannica 1900–02; in 1902 he wrote the dramatic notices of the New York *Times,* and in 1905–08 those of the New York *Sun.* From 1908 to 1910

he was literary manager of the New Theatre, 1908–10; again dramatic critic of *The New York Times*, 1917–19, and an editorial writer on the same publication after 1919. He was secretary of the Drama Society, 1912–16. Besides magazine stories and articles on the drama, he is author of 'The Elizabethan Hamlet' (1895); 'Schoolboy Life in England' (1898); 'An American at Oxford' (1902); 'A New Portrait of Shakespeare' (1903); 'The First Loves of Perilla' (1903); 'The Cave Man' (1907); 'Which College for the Boy?' (1908); 'The Edge' (1915); 'The Unknown Washington' (1930), etc.

CORBIN, Ky., city in Whitley and Knox Counties; alt. 1,046 feet; 100m. SE. of Lexington; on the Louisville and Nashville Railroad, which has repair shops here. This is a coal mining district, with farms and stock-raising. Daniel Boone cut his trace through here in 1775. The Cumberland Falls State Park (500 acres) is 19m. W. Pop. (1940) 7,893.

CORBOULD, kôr'bôld, **Edward Henry,** English water-color painter: b. London, 5 Dec. 1815; d. 18 Jan. 1905. He was a member of the Institute of Painters in Water Colors and was teacher of drawing and painting to the children of Queen Victoria, 1851–72, who acquired many of his more noteworthy productions, which were chiefly water colors. He also attained celebrity as a book illustrator.

CORCHORUS, kôr'kō-rŭs, a genus of the linden family (*Tiliaceæ*). There are about 35 species, mostly herbs or small shrubs, natives of Europe and Asia, and diffused in warm and tropical regions. The leaves of *C. olitorious* are used in Egypt and adjacent countries as a pot herb. From the fact that the Jews thus employ them they are sometimes called Jews' mallow. More important, however, is *C. capsularis,* which has long been cultivated for its fibre in China for Chinese hemp, also in India and other Eastern countries for making fish lines and nets, gunny bags, rice bags and "tat," a coarse kind of linen-like cloth. This and the former species have much more recently been used to furnish jute (q.v.). The negroes in the West Indies use *C. siliquosus* to make coarse brooms, and an infusion of its leaves as a substitute for tea. The Japanese shrub, erroneously called *C. japonicus* by gardeners, is a common garden plant on account of its pretty double yellow flowers.

CORCORAN, William Wilson, American banker and philanthropist: b. Georgetown, D. C., 27 Dec. 1798; d. Washington, D. C., 24 Feb. 1888. He was educated at Georgetown College and established himself in the banking business in Washington in 1837. He became very wealthy and was widely known for his charities and gifts to the public. In 1847 he gave the Oak Grove Cemetery property to Georgetown, founded the Louise Home for Indigent Women in Washington in 1870, and gave to the city of Washington the famous art collection known as the Corcoran Art Gallery. This he endowed munificently and it is now housed in a marble building designed by Ernest Flagg and erected 1894–97. The collection contains fine specimens of early American painters, an admirable collection of Barye bronzes and the well-known 'Greek Slave' by Hiram Powers. A free school of art is connected with the institution and biennial exhibitions of contemporary American painting contribute greatly to its usefulness. Consult Henderson, 'The Art Treasures of Washington.'

CORCORAN ART GALLERY. See Corcoran, William Wilson.

CORCYRA, kôr-sīra. See Corfu.

CORD-GRASS, or MARSH-GRASS (*Spartina*), a genus of perennial grasses containing several species, widely dispersed in America, Europe and Africa. They are often maritime; with creeping rootstocks, simple stems and long tough leaves. The spikelets carry one flower, which has unequal glumes. Fresh-water cord-grass (*S. michauxiana*) is found along river banks, lake shores and brackish coast marshes over the northern part of the United States. It is grown for binding sand and river banks, and when cut early makes fair but coarse hay. It has been used successfully for making twine and paper. It is also used for thatch. Fox-grass (*S. patens*) is rather slender and somewhat wiry, and is abundant on salt marshes; with black grass (*Juncus gerardi*) it furnishes most of the salt hay these meadows produce. It is used for packing glassware, etc. Creek-sedge, thatch, or salt marsh-grass (*S. glabra*) grows along ditches and creeks of the Atlantic and Pacific coasts. It flowers from July to October, and is used for making ropes. When young it is eaten by stock.

CORDAGE. This is the general name for all manufactures of string, twine, cord, lines, rope, hawsers and cables made of twisted fibres. Fibres are first combed out or drawn into parallel position, and then a few are twisted together forming yarn or thread. Two or more yarns twisted together oppositely form a strand. Two or three small strands twisted form string or twine. A thick string is termed a cord, and three or more cords laid together form a rope. There is no fixed and accepted definition of the terms cord and rope, however. Some manufacturers use the word rope for all diameters of an inch or more, and some begin at the half inch. The public speak of a half-inch clothes*line,* and the mariner calls small ropes *lines.* It therefore appears that small ropes are called cords and lines indiscriminately. The manner of twisting the cords to form a rope determines the lay. Three ropes are laid together to form a hawser and three hawsers a cable. The common lay consists of three strands or cords, but a shroud-laid rope has a core about which three other strands are laid. Binder twine is made with a right-hand twist, but rope-yarn requires both right-hand and left-hand twists. Ropes have to be lubricated to keep them from wearing out by their own internal friction, and also to keep out the moisture which would invite rot. Sometimes tallow or graphite with fish-oil is used, but tar is the cheap and common lubricant. In making tarred rope the yarn is unwound from bobbins to coppers, and in its travel dipped in hot tar, being then passed between rollers to squeeze out the excess of tar and spread it uniformly. Where nine-thread and larger yarn is used the tarring is usually deferred, being applied in the completed rope. Wire ropes are not a part of the cordage industry. (See Telpherage). Although rope-making constituted one of the most important branches of business from the

earliest days of the American colonies, like almost all the local manufacturies, it was many years before it began to develop sufficient strength to entitle it to be regarded as an industry. The first rope-walk in America was constructed at Boston by John Harrison in 1642, just 12 years after the town had been founded, and prior to this time, all such products that had been required in the making of rigging and tackle were either brought direct from England by the captains of the various vessels, or were imported into this country for sale. In fact, it was not until the Boston shipbuilders had commenced the construction of the 160-ton *Trial* that the several advantages to be derived from a local rope-walk were fully appreciated, and it was at their instigation that Harrison, a Salisbury rope-maker, was invited to come to Boston, where he set up his «ropefield,» 10 feet 10 inches wide, on the land adjoining his house on Purchase street, at the foot of Summer street. At this time such work was done out of doors. Posts large enough to permit of the making of the largest sizes of rope then in use were firmly fixed in the ground in open fields, and upon these the cords were suspended and the ropes made.

Harrison's coming to Boston had been largely due to the fact that he was assured that he should have a monopoly of the business for a term of 21 years, and when, at the end of that time, the town officials gave permission to a John Heyman to «set up posts,» the fact that the latter was restrained in business to the «libertie onely to make fishing lines,» did not prevent the older rope-maker from protesting against what he considered the invasion of his rights. Accordingly Heyman's license was revoked, and Harrison had everything his own way up to the day of his death.

With the «original» rope-maker dead, however, the business began to extend its influence into other parts of the town. Rope-walks multiplied in number most rapidly in the West and North Ends, until there were finally no less than 14 of them. In 1793, an additional impetus was given to the business by the action of the general court in granting a bounty for American-made rope. On 30 July 1794, the date of the great fire, seven rope-walks were destroyed, and the selectmen, who had been flooded with protests from citizens who objected to this business being carried on in the heart of the town, refused to grant further licenses except upon the low lands west of the Common. As the result, six large rope walks were immediately constructed at that point. They ranged from 20 to 24 feet in width and were each about 900 feet in length. Destroyed by fire in 1806, five of them were rebuilt, only to be burned again in 1819. During the first year of the mayoralty of the elder Quincy, the walks were removed still further out of town for the purpose of improving the neighborhood around the Common, but by the latter part of the 18th century the industry had assumed such proportions that it was generally admitted that «the men employed in this work outnumbered any other class of mechanics in Boston.» At this time the work in the rope-walks was performed by hand, the method having been described by Longfellow in his poem, 'The Ropewalk.' The twisting of the fibres was accomplished by a man who walked backward down the «walk,» spinning from the hemp which was strung around his waist. The twist was imparted to the rope by a wheel, which was at first turned by a boy, although this purpose was afterward attained by the use of horse, or even water power.

It was not to Boston alone that the early industry of rope-making was confined, however. Nantucket, in the old days of her prosperity, had three large rope-walks, all of which long ago disappeared; there was one at Castine, Me., one at Portland, Me., and several in other parts of the country, including one on Broadway, New York. In 1810 there were 173 rope-walks in the United States.

The large business which is now conducted on the Pacific Coast was instituted by A. L. Tubbs of California, sometime in the fifties, who purchased the machinery of one of the old Boston plants and shipped it to California, where two or three large factories now stand as monuments to his enterprise.

Prior to about 1850, nearly all the spun yarns used in the making of cordage were imported by the American manufacturers. As such yarns were the product of Russian serf labor, they could be brought to this country and sold for less money than similar yarns could be produced in America, so it was not until the introduction of improved machinery reduced the cost of local manufacture that the importation of this raw material ceased.

The modern factory system began to take the place of the more crude and primitive methods of making rope soon after 1830, and from that time until 1850 the conflict between the two modes of manufacture was waged with considerable bitterness. By the new system it was possible to spin a rope several thousand feet long upon an upright apparatus that occupied but a few feet square, the necessary twist being imparted by a rapidly rotating machinery which was not unlike that which is used in cotton and woolen mills. At the same time, while its cost was cheaper, the factory-made product was not an entire success. There were purposes for which the rope made by the rope-walk method was far superior, and the makers of the old-fashioned article used the words «patent cordage» to disparage the factory-made product. As time passed, however, the invention of improved machinery tended to put an end to such rivalry. The most important inventions are those of John Good, of New York. It was his spreaders and breakers that did away with the use of lappers, and his nipper and regulator on spinning-machines that gave such universal satisfaction until the perfection of the «preparation machinery» evolved methods that superseded his process.

The rope-forming machine has a gage-plate through which the threads pass, a capstan on which the first cord is twisted, a right-and-left-hand screw to guide the cord back and forth on the winding-reel, and the necessary driving mechanism. It delivers accurately twisted strands or cords which go to the laying machine. This draws in the cords, with a tension-regulating device, twists them by means of a capstan, and winds them on a large reel. Ropes are commonly marketed in coils of 1,200 feet length. A 10,000 foot rope has been made without a single splice.

Cotton is used for making string, and some cord and rope. It makes a neat white string

that can be readily dyed. It is a useful material for bands, as in cotton spinning, but cotton rope costs more and is less durable than hemp. The great bulk of the manufacture in the cordage industry is of either imported Manila fibre or sisal (Mexican hemp). The Manila hemp is from the herb *Musa textilis* of the banana family. Sisal is from the *Agava Ixtli*, of Yucatan and Mexico. The best hemp fibres are 6 to 12 feet long, and test ropes of 1¼ inches diameter have been made to withstand a tensile strain of 50,000 pounds. The twisting has to be done scientifically not to weaken the fibre. In modern practice the strands are often flattened so that they will lie closely in the rope or cable.

It was the invention of the self-binding harvester that played an important part in furthering the interests of the industry, and, about 1878, the mills of the country began to increase their size and output to a noticeable degree. Among the most prominent factories started prior to or during that period, one may mention the establishments of Sewall, Day & Company, of Boston; the Pearson Cordage Company, of Boston; J. Nickerson & Company, of Boston; Weaver, Filter & Company, of Philadelphia, afterward, as at the present time, Edwin H. Filter & Company; the Plymouth Cordage Company, of Plymouth, Mass.; the Hingham Cordage Company, of Hingham, Mass.; the New Bedford Cordage Company, of New Bedford, Mass.; Baumgardner, Woodward & Company, of Philadelphia; J. T. Donnell & Company, of Bath, Me.; William Wall & Sons, of New York; Lawrence Waterbury & Company, of New York; Tucker, Carter & Company, of New York; the Elizabethport Steam Cordage Company, of New York; Thomas Jackson & Sons, of Easton, Pa.; J. Rinek's Sons, of Easton, Pa.; and John Bonte's Sons, of Cincinnati.

As may be seen from the above list, the cordage industry, even in those comparatively recent times, was largely confined to towns either on the coast or in close proximity to the seaports, for those were the days when the great demand for cordage was for export purposes, or for the direct use of ships temporarily located at the American ports. Later, such factors as the decline in American shipping; the substitution of wire for hemp standing rigging, and the increased demand for binder twine, so altered the conditions of the industry that the location of factories became a matter of secondary importance. Thus, they began to multiply in the interior, especially in the Middle West, such cities as Akron, Peoria, Xenia and Miamisburg, becoming a new centre for the industry.

In 1843 the total quantity of manila hemp that was manufactured in the United States amounted to only 27,820 bales, or 7,511,400 pounds. To realize the ridiculously small proportions of such a product, it is only necessary to remember that any one of several of the large mills in this country could now manufacture the same quantity of hemp in less than 50 days, by running day and night, or that a similar quantity of hemp could now be brought direct from Manila in about the same length of time by the use of two steamers. So rapidly did the industry expand, however, that, by 1863 it had increased in size to no less than five times, while the period of the Civil War created such a demand for cordage that the factories in the North were utterly unable to comply with it. The profits of one Eastern factory alone, during that period, amounted to more than $500,000 a year, and this was no exceptional case, for everywhere manufacturers were fairly inundated with orders that they simply could not fill. It was about 1860 that the first sisal hemp was imported into the United States. Purely an experiment in the beginning, less than 200 tons having been used during the first year, the product was so favorably received by the trade that it soon became one of the great factors in the cordage industry, a fact which fully accounts for the rapid increase in importations from the paltry 200 tons to the amount of our present imports, a quantity that is greatly in excess of 100,000 tons.

During these years no action had ever been taken to regulate the price of cordage. Business had extended until the American product was accounted a factor in almost every part of the world. To meet these ever-widening demands, factories had increased, both in number and in the importance of their output, but no effort had been made to fix the price of the product. As the result certain abuses had come to prevail among the firms engaged in the business, and it was to meet this situation and better, if possible, the condition of affairs, that the first meeting of the cordage manufacturers was held early in 1861. The result of this meeting was an agreement, which was perfected and signed, on 23 February. Thereafter weekly meetings were held by the manufacturers, at which trade conditions were not only discussed, but any complaints were considered, and regulations were effected respecting the standard of prices. From time to time the agreement of 1861 was amended, and in July 1874 a complete revision was adopted, the manufacturers pledging themselves, «as men of honor and integrity,» faithfully to observe all its provisions. In April 1875 a still stronger agreement was made, but as complaints about underselling were still made, and as, in the absence of any specified penalty, it was necessary to accept any reasonable excuses, the manufacturers finally decided to adopt what has since been known as the «pool system.» According to this system, which went into operation 1 Jan. 1878, the business of the country was divided among the various manufacturers in what was deemed just proportions. When the business of either of these concerns in any one month exceeded the proportion which had been assigned to it, it was compelled to pay a certain amount per pound on the excess to the treasurer of the «pool,» while the concern that fell behind the specified production received a gratuity to a corresponding extent. The novelty of the plan acted in its favor for a time, and, although it did not entirely put a stop to the custom of cutting prices, it worked so well that the scheme was continued from year to year. The percentages ranged from 1¼ to 1 per cent.

In January 1880 the amount of the pool was reduced, by stages, from 2 to ¼ of a cent per pound, and in January 1881 it was abolished altogether. By 1882 conditions had become so unsatisfactory that it was found necessary to re-establish it and, on 28 June, new proportions were agreed upon. These remained in force for a period of three years, when the new concerns that had been formed were taken into the

"pool," and after much labor, a new adjustment of proportions was accepted in July 1885, remaining in existence until April 1887, when it was broken up.

The history of the National Cordage Company, the next attempt to associate the various cordage manufacturers, dates from 1 Aug. 1887, when four of the leading New York concerns formed themselves into a "trust." Their aim was to control the price of manila and sisal hemp, but the effort was a failure. In January 1890, an attempt was made to compel other manufacturers to join their organization. As none of those who complied with these demands knew the terms which had been made with his neighbor, a condition of distrust was engendered which finally, 4 May 1893, drove the corporation into the hands of a receiver, in spite of the fact that it had paid 8 per cent dividends on its preferred stock since 1891, and from 9 to 10½ per cent on its common, the last dividend being declared on both only three days before the failure.

As the result of the reorganization the United States Cordage Company was formed, but as this corporation was also unsuccessful in its schemes to monopolize the purchase of raw material, the factories which had been purchased by the National Cordage Company went back into the market. Some of them were repurchased by their former owners or their representatives; others went into new hands.

An unusual factor in the cordage trade was represented by the binder twine situation. In the beginning, when there was considerable doubt as to the success of the twine, the cordage houses made it for the manufacture of harvesting machinery at a profit of several cents a pound. When the market position of this produce was established, the harvest-machine makers began to manufacture their own twine, and while this was done at a third of its original cost, the loss of these contracts was a serious setback to the cordage industry. According to the United States census of manufactures for 1914, the total number of establishments engaged in the manufacture of cordage and twines was 103. Their output for that year amounted to 487,443,356 pounds of rope and binder twine, valued at $43,085,517; cotton rope, 13,244,198 pounds, valued at $2,539,906; and other twine, 105,249,677 pounds, valued at $13,996,522 — a total value of $59,621,945.

The output of twine, other than binder twine, was valued at $13,996,522, an increase of 56.7 per cent since 1909. This value comprises that of twine made from cotton, jute, hemp, flax and other materials. The output of cotton twine in 1914 was 17,927,286 pounds, valued at $3,472,056, representing a decrease of 12.2 per cent in quantity and 1.3 per cent in value as compared with the 1909 figures. Of jute twine the 1914 production — 55,282,159 pounds, valued at $5,268,357 — showed an increase during the five-year period amounting to 55.7 per cent in quantity and 106 per cent in value. Hemp twine showed an increase of 16.3 per cent in quantity and 45.1 per cent in value, and flax twine an increase of 33.3 per cent in quantity and 26.6 per cent in value. The output of other twines, including those made from mixed materials, increased 110.7 per cent in quantity and 179.9 per cent in value.

Of the total value of products in 1914, $83,228,424, that of rope and binder twine represented 54.8 per cent. Exclusive of cotton rope the output of these products increased from 411,443,281 pounds valued at $30,918,693, in 1909, to 487,443,356 pounds, valued at $43,085,517, in 1914, or by 18.5 per cent in quantity and 39.4 per cent in value.

In 1927 there were 116 establishments engaged in the manufacture of cordage and twine in the United States. These employed an average of 15,084 wage-earners to whom was paid wages totaling $13,674,000. Materials used by these industries cost $56,105,000 and their output was valued at $89,172,000, the value added by manufacture having been $33,067,000.

The output and value of rope, cable, and cordage manufactured in 1927 was as follows: Manila hemp, 105,614,000 pounds, valued at $22,607,000; sisal, 30,712,000 pounds, valued at $4,439,000; hennequin 12,992,000 pounds, valued at $1,840,000; cotton, 27,404,000 pounds, valued at $7,602,000; all other rope, etc., 55,929,000 pounds, valued at $8,154,000.

The output of binder twine in 1927 amounted to a total of 169,795,000 pounds, valued at $19,457,000, while the output of twine, other than binder twine, totaled 74,065,000 pounds, valued at $12,813,000. In 1927 the output of cotton twine alone amounted to 64,208,000 pounds, valued at $20,160,000. Yarns, chiefly jute yarns, totaled 88,539,000 pounds, valued at $15,742,000.

CORDAITALES (from the genus *Cordaites,* named in honor of A. J. Corda), an extinct great group of naked seeded and primitive gymnospermous plants, resembling in certain respects the cycads and cycadeoids, ginkgo, especially the yews among conifers, and the araucarias. The Cordaitaleans are the most ancient of well-known seed-plants. They must have evolved in the Silurian or earlier; in the Devonian they formed the world's first great forests; throughout the Carboniferous they remained cosmopolitan elements of climax forests; while in the Permian they declined, and the record closes in the Lias. In North America large and finely silicified trunks occur in Canada, Ohio, Indiana, Oklahoma and elsewhere. Some of the sections of petrified trunks from the Black Shale (upper Devonian) of Indiana are two or more feet in diameter by 20 feet long, and indicate stately forest trees from 100 to 150 feet high. In portions of the *Cordaites* shale of New Brunswick the leaves often occur packed in layers like those of modern forests. The group appears to have culminated in the upper Carboniferous coal-swamp forests. There the stems and leaves with a great variety of staminate fruits and seeds are especially abundant. The most noteworthy Cordaitalean specimens are the silicified leaves, stems and fruits with microscopic structure preserved from the "black flints" of the Coal Measures of Grande Croix, France. Study of this material, together with various trunks, casts and imprints, has revealed nearly all the critically important structures of these long-extinct plants.

The Cordaitales were mostly tall and rather slender trees with columnar trunks which only branched freely near their summits. The leaves were usually large and spirally inserted. In foliage and habitus various forms were much like *Dammara,* the New Zealand Kauri pine

(Fig. 1); but some of the types must have greatly resembled *Araucaria imbricata* (q.v.). The larger species even as far back as the Devonian vied in size with both of these modern climax forest makers. Some of the strap-leafed types must have had the appearance of the screw pine. Large leafed forms like that of figure 2 branched less freely or were simply columnar. The leaves are of linear to broadly elliptical form, and vary rather more than in the modern conifers. Smaller species are no more than 10 centimeters long; but a leaf length of two metres with a width of 20 centimeters is sometimes reached.

On the basis of the leaf forms Grand 'Eury

FIG. 1 — *Dorycordaites* as first restored by Renault. Numerous catkin-like inflorescenes are interspersed among the lanceolate leaves. The usual habitus was much taller. Bark not shown. × $\frac{1}{100}$.

divided the group into the genera *Cordaites, Dory-* and *Poa-Cordaites.* The first of these divisions (cf. Fig. 3) includes mainly very large spatulate and blunt-end leaves, the second large lanceolate and sharply pointed leaf types, and the third grass-like forms. The genus *Cordaites,* as first used, may include any of these. Isolated stems have usually been described as *Cordaioxylon,* or often as *Araucarioxylon,* because of the structural similarity to the wood of modern Araucarias. Branches can be called *Cordaicladus,* and the large isolated pith casts, looking like piles of coins, were long only known as *Artisia* or *Sternbergia.* Staminate fruits are named *Cordaianthus,* and the seeds *Cordaicarpus.* On the basis of wood structure classification is likewise provisional, since studies of entire stems are seldom or never possible to carry out. Three more or less overlapping divisions are also distinguished by Scott. (1)

FIG. 2 — Large leaf simple-stemmed Cordaitalean with prolonged fertile axis. × $\frac{1}{50}$. From Dawson.

The Poroxyleæ were far the most fern-like. The stems were slender, only a few centimeters in diameter. They had long internodes and a double leaf trace bundle as in *Lyginopteris,* from which they mainly differ in their lack of centrifugal primary xylem. The petioles are known, and the bi-lateral seeds called *Rhabdocarpus* appear to belong here. (2) The Pityeæ include *Pitys* (with three species from the lower Carboniferous of southern Scotland), *Archæopitys* of the Waverly shale of Kentucky, and *Callixylon.* A very fine stem of the latter from the Indiana Devonian is called *Callixylon Oweni,* and a related species is Russian. This

FIG. 3 — *Cordaites lingulatus.* Group of attached leaves. After Grand 'Eury. (Reduced.)

group is only known from the pith and wood. The trees reached large size, but still retained mesarch strands of primary xylem traversing the medulla next the secondary wood. They are thus of great interest as forms intermediate

between the fern-like Poroxyleæ and typical Cordaiteans. (3) The Cordaiteæ are the most advanced type and the greatest forest makers. Some species reached 150 feet in height and three feet in diameter. The stems still more closely resemble *Araucaria* in structure, the elements of the wood all being radially arranged. No distinction between primary and secondary wood appears in the transverse section. The strands of "old cryptogamic wood," characteristic of the preceding divisions, are lost. In the radial section narrow spiral elements of the protoxylem next the broad discoid pith are succeeded by wider spiral tracheides, many rows of scalariform elements, and lastly the pitted tracheides forming the bulk of the wood. The pits of this wood are generally in two or more densely crowded rows. Their alternation tends to produce hexagonal outlines, though isolated pits retain their circular form. The pore is usually an oblique slit, and the crossed slits of appressed facing pits are highly characteristic. The medullary rays are thin, mostly one cell thick. The secondary wood is thus quite indistinguishable from that of *Araucaria*. The phloem is radial, the cortex parenchymatous and provided with secretory sacs. The outgoing leaf traces are double, as in *Araucaria*, *Ginkgo* and various primitive gymnospermous forms. There was a thick bark, recalling that of *Araucaria*. As in that modern type there are diarch roots with spiral protoxylem and the scalariform tracheides, followed by the secondary pitted wood. Triarch and tetrarch roots of similar structure are known. The very large cycad-like pith of all these stems appears to owe its discoid structure to tension during growth; but this feature may be seen in various modern plants such as the hickory and the walnut. Growth rings of the discontinuous or Araucarian type may occur. Amongst forms structurally antecedent to the three foregoing groups, and more fern and cycad-like may be mentioned the stems classed as the *Calamopityeæ* with petioles known as *Kalymma*. Well-conserved forms of these occur in the Waverly of Kentucky at the close of Devonian time. The leaves of the Cordaitaleans are conspicuously parallel veined with repeated dichotomy in all but the narrowest grass-like forms. Anatomically they are very similar to the single pinnules of either the cycads or the cycadeoids. As in the latter the structure is well known from silicified specimens. The bundles are usually described as of the mesarch type, but the centrifugal xylem may fail. Each is surrounded by a strong sheath, usually connected with heavily developed hypodermal sclerenchyma. Intervening strands of the latter tissue may correspond to the leaf secondary venation.

Fructification.—The knowledge of the morphology of the Cordaitales now constitutes one of the most interesting chapters in botany. It largely rests on the labors of Grand 'Eury and Renault, the latter having been fortunate as to find silicified strobili of The cones of certain species preserved in places showing detail in the siliceous fragments or cans). Grande Croix. Both male and female French Cordaites as well as seeds, have often been found in the attached to the leafy stems or branches Miscan (Fig. 5, 7). The numerous flowers are de Méd more or less catkin-like male and female inflorescences. Such recall those of Gnetaleans or even angiosperms. The floral order is usually spiral but may be distichous. No amphisporangiate flowers are known, although one form, *Cordianthus Penjoni*, suggests that such may have occurred. The usual condition indicates either monœcism or dioecism. The staminate flower is about a centimeter long and consists of a thick axis covered by spirally arranged bracts with interspersed fertile filaments bearing erect tufts of sporangia (Fig. 5).

Fig. 4.—*Cordaianthus Pitcairniæ*. Branch of monœcious form bearing leaves and leaf scars with an ovuliferous inflorescence on the right, and on the left an inflorescence consisting of small staminate strobili. After Grand 'Eury.

Or, as Renault says, "In the midst of the sterile bracts arose one or more fertile bracts, the filaments of which scarcely modified bore at their summits three or four sacs containing the pollen." There is, therefore, a noteworthy analogy to the ovulate cones of the Cycadeoids. In these the stems bearing single erect seeds are likewise interpolated amongst sterile organs or scales.

The pollen grains which have been found both in place and actually in the pollen chambers of the macrospores are large and contain

A B

Fig. 5.—*Cordaites angulostriatus* from the French Stéphanien. A, branch with male inflorescence, slightly reduced; B, single bud with protruding anthers, enlarged from Grand 'Eury.

a highly interesting group of prothallial cells. This group is theoretically a transition stage between Pteridophytes and Spermatophytes. An extraordinary instance is recorded. In a seed of *Cordianthus Grand 'euryi* the outer integument is partly broken away, the nucellus being left standing free. In its upper end the pollen chamber contains the pollen grains as in *Ginkgo* and the cycads. An actual stage in pollination is thus seen. It is of fundamental importance

that the pollen grains found in the nucellar canal are larger than those in the sporangia, and their group of internal cells more developed; while grains found free in the matrix exhibit an intermediate condition. Evidently the pollen grains continued to grow after their discharge from the anther, and especially after entrance into the pollen chamber. Such a condition is one of the most readily thinkable later stages in the evolution of heterospory and seeds from asexual spore-producing diœecious free prothalli. The presence of free swimming spermatozoids is surmised.

The seed-bearing spikes are of varied form; in some, solitary ovules accompanied by a few bracts are inserted directly on the axis (Fig. 6); in others this arrangement appears to be compounded, the lateral catkins each containing several ovules and in their younger stages much resembling the staminate forms. The ovule was thus borne on a short axillary shoot as in *Taxus* or *Ginkgo*. In such forms basal stamens may earlier have been present, forming a *Tumboa*-like fruit (Fig. 5). While homology with other gymnosperms is not very close, it is evident that this open type of inflorescence was capable of undergoing change in the direction of modern forms of compaction and reduction. Undoubted Cordaitean seeds (those found attached) are mostly cordate, and flat or platyspermic. The winged seeds about a centimetre long called *Samaropsis* (Fig. 7), were attributed by Grand 'Eury to the genus *Dorycordaites*, seen in the restoration Fig. 1. Others reach five or more centimetres in length, and owing to their size, heavy angles, and thick testa, are also fossils of striking conservation. But there is no gap either of structure or of form separating such seeds from the larger radiosymmetric types abundant in the Palæozoic. In general the Cordaitean testa is more or less distinctly triple-layered, if the sclerotestal tissue separating the outer fleshy sarcotesta from the inner flesh be called a layer. The chalazal bundle may give off branches into both the inner border of the sarcotesta and the nuceleus. In a form called *Cycadinocarpus angustodunensis* the archegonia are plainly present, but embryonic structures have never been observed in such seeds. They are scarcely separable from those of the quasi-ferns and greatly resemble the seeds of modern cycads. The seeds of the cycadeoids, owing to reduction, present a far less visible similarity.

FIG. 6—*Cordaianthus spicatus* Lesquereux. Diagrammatic, showing involucrate nutlets distichously to subalternately borne on both sides of a thick rigid stem. Involucral scales embracing the nutlets indistinct. From the coal measures of Pittston, Penna. One half natural size.

The Cordaitales derive a unique significance from their age and primitive characters, so manifestly important in our conception of the manner and course of plant evolution. Botanists have been inclined to believe that the Cordaitalean and Cycadalean groups had a common filicalean ancestry, and that from the Cordaitales have been derived the Ginkgoales, the Coniferales and probably the Gnetales. Some would go further and place the Cordaitales in a position ancestral to angiosperms as well. Opinion is about equally divided between a Cordaitalean and an Equisetalean derivation of *Araucaria*. Recent investigation calls these theories of descent more in question. It is now recognized that fossil types are seldom the true antecedents of later forms. Most fossil plants represent terminal climax constituents in the floras of the past; while the extent of homoplasy and parallelism yet remains to be measured. Certainly increasing knowledge of the Cordaiteans will show them to be more varied than as yet conceived, and in any case their discovery must be regarded as one of the great triumphs of palæobotany.

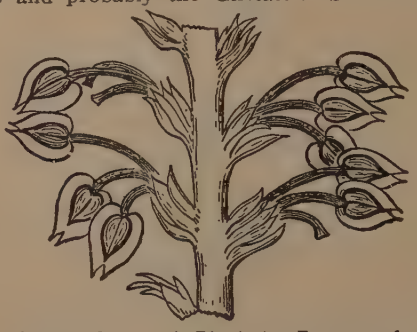

FIG. 7—*Samaropsis Pitcairniæ*. Fragment of an ovulate inflorescence from Westphalia with the seeds in groups and borne on elongated stems. Natural size. After Carruthers.

Charlotte Corday to revenge. History had inspired her with a deep-rooted hatred against all oppressors, and she determined to free her country from Marat. Having left home, she entered Paris 11 July 1793, and obtained an interview with Marat on the pretext of disclosing Girondists' plots. In the *Ami du Peuple* of that morning Marat had asked for 200,000 heads, and Charlotte told him she could give him those of the Girondists at Caen. The assemblies at Calvados were the first subjects of conversation, and Marat heard with eagerness the names of those who were present at them. «All these,» he exclaimed, «shall be guillotined.» At these words Charlotte plunged her dagger into his bosom, and he called out «*A moi! mon ami*»; when some attendants rushed in and seized her. On the morning of 17 July she appeared before the revolutionary tribunal with a dignified air, and her replies were firm and noble. She spoke of her deed as a duty which she owed her country. Being condemned to death she was guillotined the same day, retaining her presence of mind to the last. Her remarkable beauty, and her lofty bearing on her way to the guillotine, sent a thrill even through the hearts of her executioners. One young German enthusiast, Adam Lux, a deputy from the city of Mentz, on witnessing the execution, conceived a romantic passion for her, and when her head fell, he cried with a voice hoarse with emotion: «She is greater than Brutus.» He wrote a pamphlet, suggesting that a statue with such an inscription should be erected to her memory. He was arrested and guillotined. André Chénier, who had paid a glowing poetical homage to her heroism, shared the same fate before a year had elapsed. When Vergniaud was informed of Charlotte's death, he exclaimed: «She has killed us, but she teaches us how to die.» Consult the various 'Lives' by Dubois (1838), Defrance (1909), Huard (1866), Vatel (1872); Lamartine, 'Histoire des Girondins.'

CORDELE, Ga., city and Crisp County seat; alt. 336 feet; 65m. S. of Macon; on the Southern and other railroads. It is a peanut distribution center. Pop. (1940) 7,929.

CORDELIA, the youngest daughter of Lear in Shakespeare's tragedy, 'King Lear.'

CORDELIERS, kor-dā-lē-ā. 1. Another name for the Franciscan friars in general, but given, in France, to the branch of the order usually known as Franciscan Friars Minor (O. F. M.). After the death of Saint Francis in 1226, the next minister-general of the order relaxed somewhat the rigor of the rule of poverty as taught and practised by Saint Francis. This relaxation caused a division in the order, a number of the friars adopting the modified rule were called Conventuals (O. M. C.), and those adhering to the original observances were called Observantines, and later, Friars Minor. In France the name Cordeliers was given to them on account of their girdle. The Cordeliers or Friars Minor are in several places in the United States. (See FRANCISCANS). 2. A political club during the first French revolution, which received the name of Cordeliers from the fact that its members met in the chapel of the old convent of the Franciscan friars situated near the Rue de l'École de Médicine and the Rue de l'Observance, in the centre of the quarter of Paris known as the Cordeliers' district. The club of the Cordeliers became the focus of the wildest agitators, while at the same time it was constantly quarreling with the Jacobin Club. The leading events of the reign of terror may be traced to the conflict of the two clubs, and chiefly to the influence of the Cordeliers, of whom Marat and Danton were the ruling spirits. Anacharsis Clootz was also one of the members. At the time the club was in its zenith, Camille Desmoulins edited a popular journal in connection with it, under the name of *Le vieux Cordelier,* without, however, identifying himself completely with the politics of the formidable club. They were the first to demand a republic, insisting on «Liberty, Equality and Fraternity.» After the execution of Danton, Hébert and Chaumette, the club declined in influence, and was closed by the law of 6 Fructidor, or 23 Aug. 1795. Consult Bougeart, 'Projet d'organisation des Cordeliers' (Paris 1870).

CORDELL, Okla., city and Washita County seat; alt. 1,532 feet; 111m. SW. of Enid; on the St. Louis-San Francisco Railway; raises grain, cotton, broom corn; has dairy, poultry, livestock, nursery interests. Pop. (1940) 2,776.

CORDIER, kôr-dyā, **Henri,** American educator: b. New Orleans, La., 8 Aug. 1849. He was educated in Paris and professor there at the School of Political Sciences, and the School of Oriental Languages; was a member of the Council of the Asiatic Society and honorary member of the Royal Asiatic Society, president of the Société de Bibliographie, member of the Institut de France and Chinese mandarin. He published 'Catalogue of the Library of the North China Branch of the Royal Asiatic Society' (1872); 'Narrative of Recent Events in Tong-king' (1875); 'Bibliotheca Sinica: Dictionnaire bibliographique des ouvrages relatifs à l'Empire Chinois' (2 vols., 1881–85; Suppl., 2 vols., 1895; 2d ed., 4 vols., 1904–08); 'Les voyages en Asie au XIV^e^ siècle du bienheureux frère Odoric de Pordenone' (1891); 'Histoire des relations de la Chine avec les Puissances Occidentales' (3 vols., 1902); 'L'Expedition de Chine de 1857–58' (1905); 'L'Expedition de Chine de 1860' (1906); 'La Chine en France au XVIII^e^ siècle' (1910); 'Bibliotheca Indo-Sinica' (1913–). He edited the third edition of Yule, 'The Book of Ser Marco Polo' (2 vols., 1903), and the same author's 'Cathay and the Way Thither' (1913). After 1890 he edited *Tsung Pao,* a review of Oriental affairs. He died at Paris in 1925.

CORDIERITE, a name formerly given to the mineral iolite (q.v.), in honor of Cordier, a French geologist.

CORDILLERAS, a name from the Spanish for a mountain chain or ridge, formerly applied to any lofty and straight areas of land, but now specifically to chains, ranges or ridges of mountains, and especially to such of these elevations as are long and continuous. It is used particularly in physical geography, although in geology also it is sometimes applied to mountain systems at or near the coasts or borders of continents. The name was first given by the Spaniards to the chains of the Andes in South America, and was afterward extended to their northern continuation through Central America and Mexico, and finally to the

entire mountain systems stretching up the western coast of the United States, British Columbia and Alaska, and spreading eastward to include the Rocky Mountains (q.v.). This portion of the continent geographers have come to call the Cordilleran region of North America, designating the corresponding elevations of South America under the old name of Andes. This region covers in the United States the whole western mountain portion of the country, including the Sierra Nevada, the Coast Range, the Cascade Range, and extending to and embracing the Rocky Mountains, as well as all the ranges lying between them and the mountains of the western coast. Included within this Cordilleran region are mountain systems many of whose lesser chains, in length and elevation, equal some of the famous ranges of Europe.

CORDITE, a smokeless powder employed by the English government. It was invented in 1889 by Sir Frederick Abel and Prof. James Dewar, and originally consisted of a mixture of nitro-glycerine 58 parts, nitrocellulose 37, vaseline 5, but on account of the erosion of the bore caused by the high percentage of nitro-glycerine and the danger of exudation of the nitro-glycerine and consequent detonation, the present proportions are more nearly 15 parts of nitro-glycerine, 80 of nitrocellulose and 5 of vaseline. This demanded an increase in the capacity of the gun chambers. This was done gradually, so that guns of earlier design could be used till they wore out.

The nitrocellulose is a mixture of various cellulose nitrates, insoluble and soluble. At the Royal Gunpowder Works at Waltham Abbey it is required that the nitrocellulose used shall not contain more than 12 per cent of soluble cellulose nitrate, or 0.6 per cent of mineral impurities, nor less than 12.5 per cent of nitrogen. It is made by intimately mixing the ingredients in a mechanical kneading-machine with the aid of acetone, by which the whole is converted into a gelatinous mass which is then squirted into cords by means of a "stuff press," a machine similar to those used in forming macaroni. The cords vary in diameter from 0.01 inch to 0.65 inch. The former are chopped into short lengths for use in pistols, the latter for use in 12-inch guns. The cords for small-arm cartridges are 0.0375 inch in diameter. The cords are heated in drying houses to drive off the acetone, leaving them in the form of an amber-colored, translucent, flexible mass.

Cordite is made up into charges by re-ling the cords on bobbins, and then spinning these strands into larger cords, thus obtaining the desired length, volume and weight. See EXPLOSIVES; NITROCELLULOSE; SMOKELESS POWDERS.

CÓRDOBA, kōr'dō-vä, **Fernando Fernandez de**, Spanish general and statesman: b. Madrid 1792; d. 1883. He entered the military service in 1810, and was rapidly promoted during the war with Napoleon. In 1847 he officiated for a short time as Minister of War, and was appointed inspecting general of the infantry. On 8 March 1850 he was made captain-general of New Castile; in the following year to the same position in Cuba, and in 1853 general-in-chief of the cavalry. Immediately after the outbreak of the revolution of 1854, he was called upon by the queen to form a new cabinet. This he declined, but he ordered his soldiers to fire upon the insurgents, and when the latter proved victorious, he fled to France. In 1856 he returned to Spain, and was reinstated in his position of general, and 10 years later was active in the revolution which drove Queen Isabella from the throne. He was captain-general of Cuba for the second time in 1870.

CÓRDOBA, Francisco Hernandez de, Spanish soldier and explorer. See HERNÁNDEZ DE CÓRDOBA, FRANCISCO.

CÓRDOBA, José Maria, South American general: b. Antioquía, Colombia, about 1797; d. 17 Oct. 1829. At the age of 15 he left his father, who belonged to the Spanish party, and joined a band of guerrillas, among whom he soon became noted for his intrepidity in their contests with the Spaniards. At the battle of Boyaca, 8 Aug. 1819, he won the rank of colonel. Not long after he was appointed general, and distinguished himself at the battle of Ayacucho, after which he was made general of division on the field. In September 1828 he became head of the War Department of the republic of Colombia, under Bolívar, but, a year afterward, revolted against him. He found but few adherents, however, and being attacked, 17 October, by a force greatly superior to his own, was slain with the most of his followers.

CÓRDOBA, Luis Fernandez de, Spanish general: b. Cadiz 1799; d. Lisbon, 29 April 1840. He took a prominent part in the movement of 1820 as a constitutionalist, and in that of 7 July 1822 as an absolutist. He officiated afterward on diplomatic missions abroad, and eventually deserting the forlorn cause of Don Carlos, espoused that of Christina and Isabel, took a distinguished part in the battle of Mendigorria, was appointed commander-in-chief of the Christinos as successor of Valdez, but unable to finish the war, was driven from office after the movement of 1836, and fled to France, whence he soon returned to Spain. He now conspired with the party of Narvaez against Espartero, but retired to Portugal when the latter came into power.

CÓRDOBA, Pedro de, Spanish Dominican missionary: b. 1483; d. Santo Domingo, 28 June 1525. He was vicar of the first Dominican colony in Hispaniola in 1510, preached against Indian slavery and endeavored to have laws framed for the protection of the Indians. His efforts in behalf of the Indians were successful to the extent that he drew the attention of the Spanish court to the evils going on in the government of the Spanish colonies in the New World; but the influence of the adventurers who swarmed into the country shortly after the discovery of America and the cupidity of the representatives of the Crown and of the land holders finally brought his work to naught; and the Indians in Hispaniola and neighboring islands soon became practically extinct.

CORDOBA, or **CORDOVA**, Argentine Republic, a province next in size to that of Buenos Aires, bounded on the north by Santiago del Estero, on the east by Santa Fé, on the south by Buenos Aires and the territorial government of Pampa Central, and on the west by the provinces of San Luis, La Rioja and Catamarca. Area 66,912 square miles. Its northwestern portion is mountainous, and rich

in minerals. Copper, silver, gold, lime, marble, graphite and salt are found. The central and eastern regions lie in a great plain watered by the rivers Cuarto, Segundo, Primero, Dulce, etc., with the lake called Mar Chiquita; and here agricultural and grazing industries are carried on. Cattle, horses and mules are bred in the south; wheat and fruits are raised along the river courses; there are large flocks of sheep and goats in the centre and north. Besides wheat and fruits, the principal crops are maize, lucern, barley, sweet potatoes and white potatoes. Of the total productions, about one-half, in value, are pastoral, one-third agricultural. The mining industry is as yet comparatively undeveloped. Manufactures are flour, lime and cement, bricks, hides and leather, beer, wine and alcohol, boots and shoes, cut wood, vermicelli, gold embroideries, butter and cheese, cut stone, belts, candles and soap, artificial ice, etc. Principal railway centres are the capital city, Córdoba (q.v.), Villa María and Villa Nueva. Under the constitution of the republic dated 25 Sept. 1860 the province has its own constitution, «framed upon the basis of a republican representative system of government, and in harmony with the principles, declarations, and guaranties of the national constitution»; said provincial constitution relating to «the administration of justice, the administration of the local government, and primary instruction. Upon these conditions the federal government guarantees to each province the practice and enjoyment of its own constitutions.» The provinces have their own local institutions and laws; «they elect their governors, legislators, and provincial functionaries of all classes, without the intervention of the federal government.» The province is represented in the national legislature by two senators, elected by the provincial legislature, and by deputies elected directly by the people. Each province is for this purpose considered as an electoral district, and the election is by a plurality of votes in the proportion of one deputy to each 20,000 inhabitants, or fraction of that number not less than 10,000. Population of the province approximately 1,002,000.

CÓRDOBA, Argentine Republic, the capital of the province of the same name, situated on the right bank of the Rio Primero, 432 miles from Buenos Aires, at the junction of five railways. It is one of the progressive inland cities, having adopted many of the modern improvements, such as electric light, running water, street railways, sewers and excellent pavements. Its university, founded in 1813; astronomical observatory, established 1871; National Academy of Science; National Meteorological Institute; national college, normal schools and elementary schools, have made it well known as an educational centre. Railway communication with Buenos Aires was established in 1869. The first national fair was held here in 1871. A score of newspapers and reviews are published in the city. In size it is the third city of the republic. There are fine public buildings and private residences, and attractive parks. It was founded in 1583, and its university is in point of age second only to that at Lima among the South American universities. Pop. 221,200.

CORDOBA, Mexico, a town on the Mexican Railway, 66 miles west of Vera Cruz, in a fruitful valley 3,045 feet above the sea. It has manufactories of woolen and cotton goods and is surrounded by rich coffee plantations. Pop. 9,000.

CÓRDOBA, Spain, a town and capital of the province of Córdoba, situated on the Guadalquivir, in Lower Andalusia. It is built on a gentle declivity of a chain of mountains, forms an oblong quadrangle and is surrounded with walls and lofty towers. A part of the town is of Roman, a part of Moorish origin; many of the buildings are in ruins, and a number of gardens occupy a great part of the inhabited space. The streets are narrow, crooked and dirty; the plaza mayor, the principal marketplace, however, is distinguished for its size, its regularity and the beauty of the colonnade by which it is surrounded. The remains of the residence of the Moorish kings now form a part of the archbishop's palace. The cathedral is a splendid building, originally a mosque, erected in the 8th century by King Abd-er-Rahman I. The mosque of Córdoba is, in the words of Gautier, «a monument unique in the world, and novel even for travellers who have had the fortune to admire the wonders of Moorish architecture at Granada or Seville.» It is 370 feet in length, 425 in breadth and has a bell tower 300 feet high. It was at one time the second largest sacred building of Islam, and is the most magnificent Mohammedan temple in Europe. It is surrounded by a wall supported by strong buttresses. Other points of interest are the Campo Santo, the site of Christian martyrdoms, and the chapel of the Hospital del Cardinal, once part of a mosque. From the 9th to the 12th centuries Córdoba was a great centre of trade; the leather exclusively manufactured there (cordovan) was exported in all directions. At what period the Romans laid the foundation of the town (Colonia Patricia, afterward Corduba) is not known. In 572 it was conquered by the Goths. During the reign of the dynasty of the Ommiades it was the capital of Arabian Spain; and afterward it became the residence of the powerful caliphs of the West, the sacred city of the Moors and the centre of Mohammedan worship and of Arabian splendor and science. At that time the city is said to have been about 15 miles in circuit and to have possessed a population of 1,000,000. In 1236 it fell an easy prey to Ferdinand III of Castile. In 1808 it was pillaged by the French, who captured it again under Soult in 1810. Pop. 82,243. **The province of Córdoba includes the fertile and beautiful valley of the Guadalquivir and the snow-capped mountains of Sierra Morena. The area of the province is 5,299 square miles and the population about 607,000.**

CORDON, in a military sense, troops so disposed as to preserve an uninterrupted line of communication, to protect, for instance, a country from hostile invasion; also a similar line intended to protect a place from contagious diseases. In the latter sense it is called a *cordon sanitaire.* The word «cordon» also means, in fortification, the coping of the escarp or inner wall of the ditch. It is usually rounded in front and projects one foot over the masonry.

In horticulture, cordon is a term applied to a system of training fruit trees. The trees are dwarfed by training and pruning to one or two stems which extend horizontally or

obliquely, and from which the fruit-bearing spurs are developed. The objects sought are economy of space and increased size and improved quality of fruit. The system is in little use in America, where land is cheap, but in Europe it is very popular. It is best adapted to such trees as pears and apples, which naturally bear their fruits upon spurs.

CORDON BLEU, kôr'dŏn' blė, a knight of the ancient French Order of the Holy Ghost, at one time the most aristocratic order in the kingdom, whose decoration was attached to a blue ribbon or baldric. The knights frequently met in club form, and were noted for their excellent dinners, whence the term came to be applied to a cook of superior skill.

CORDON GRAND, grŏn̄, a term applied to a member of any grade of the French Legion of Honor, because the cross of the order is always suspended from a broad ribbon.

CORDOVA, Francisco Hernandez de, Spanish navigator: b. in the latter part of the 15th century; d. Cuba 1517. He was the discoverer of Yucatan, which he visited in 1517, and had several encounters with the natives. He lost some of his men, and two were taken prisoners and carried up the country. Shortly after his return to Cuba he died; but the account he gave of his discoveries led to a new expedition under Juan de Grijalva, to whom was subsequently assigned the honor of the discovery.

CORDOVA Y FIGUEROA, Pedro de, Chilean historian: b. Concepcion 1692; d. there after 1770. He served in the Chilean army in Araucania and was alcalde of his native place about 1740. He wrote a 'Historia de Chile,' which includes an account of the settlement of the country up to 1717. In 1739, by order of President Velasco, he founded Los Angeles, the capital of Araucania. The manuscript of the work was preserved at Madrid. It has been published in the 'Colección de historiadores de Chile.'

CORDOVA, Ala., town in Walker County, 30 miles north of West Birmingham, on the St. Louis and San Francisco and Southern railroads. The principal industries are the manufacture of cotton and coal mining. It has high and graded schools and churches of the leading denominations. Trucking and general farming are carried on. The government is vested in a mayor and council. Pop. (1940) 1,565.

CORDOVA. See CORDOBA.

CORDOVAN, a fine leather which took its name from the Spanish city of Cordova, where it was manufactured in large quantities. It was also called cordwain. The modern application of the term is to a grain leather from the best and strongest portions of a horsehide and used for heavy boots, as for walking or hunting.

CORDUROY, a ribbed cotton fabric, woven with a pile which is cut so as to leave the surface ridged in the direction of the warp. See FUSTIAN; VELVET.

CORDWOOD, wood, especially firewood, cut in lengths of 4 feet and piled in an oblong stack 8 feet long and 4 feet high. The cubical content of 128 feet is the standard for determining the prices of sale or of labor on the material.

CORDYCEPS, kôr'dı-sĕps, a genus of fungi, some of which are found parasitic on other fungi, while others are remarkable for growing on the larvæ of insects, which they latterly kill. It grows very freely over a wide area, and in different countries 28 species have been found.

COREA, kō-rē'ą. See KOREA.

COREAL, kō-rā-ăl', Francisco, the name affixed to the 'Voyage aux Indes occidentales,' which was issued in Paris 1727. Its author asserted that he was born in Carthagena, Spain, in 1648 and had traveled extensively through Florida, Mexico and South America. The book abounds in errors and is probably a compilation. The work passed through several editions, one of the most important of these being published in Brussels in 1736.

COREGONUS, kō-rĕg'ô-nŭs, a genus of abdominal fishes, family *Salmonidæ.* The teeth are very small or wanting, the scales large and the height or front of the first dorsal as great or greater than its breadth. The genus is common in European waters and unusually large varieties are found in the rivers of Siberia. The best-known American representative is *Coregonus clupeiformis,* the whitefish. They inhabit clear lakes.

CORELLI, Marie, English novelist: b. Italy 1864; d. England, 21 April 1924. In infancy she was adopted by Charles Mackay, the poet. On beginning her literary career adopted as a pen name that which subsequently became her legal name. She published 'A Romance of Two Worlds' (1886); 'Vendetta' (1886); 'Thelma' (1887); 'Ardath, the Story of a Dead Self' (1889); 'Wormwood'; 'The Soul of Lilith' (1892); 'Barabbas' (1893); 'The Silence of the Maharajah' (1895); 'The Sorrows of Satan' (1895); 'Cameos' (1896); 'The Mighty Atom' (1896); 'The Murder of Delicia' (1896); 'Ziska' (1897); 'Jane' (1897), 'The Master Christian' (1900); 'Boy' (1900); 'Temporal Power' (1902); 'God's Good Man' (1904); 'The Treasure of Heaven' (1906); 'Holy Orders' (1908); 'The Devil's Motor' (1910); 'The Life Everlasting' (1911); 'Innocent, Her Fancy and His Fact' (1914).

CORENTYN, kō-rĕn-tin', a river of South America, separating British and Dutch Guiana, and flowing into the Atlantic. It has a course of about 400 miles, and is navigable below the Great Cataracts in lat. 4° 20' N.

COREOPSIS, kō-rę-ŏp'sĭs, a genus of annual and perennial herbs of the family *Asteraceæ.* Nearly all the species are natives of eastern North America. They have showy, generally yellow, flowers in heads, and are widely cultivated in gardens. They are of easiest culture, being grown from seeds sown in a hot-bed and transplanted to any ordinary garden soil where they will blossom freely with little attention beyond keeping the ground free from weeds.

COREY, William Ellis, American capitalist: b. Braddock, Pa., 4 May 1866. He was educated at Duff's College, Pittsburgh. When 16 years old, he entered the chemical laboratory of the Edgar Thomson Steel Works, and five years later he went into the Homestead Steel Works, where, in 1889, he became superin-

tendent of the plate mill, in 1893 superintendent of the armor-plate department, and in 1897 general manager. From 1901 to 1903 he was president of the Carnegie Steel Company and from the latter year to 1911 president of the United States Steel Corporation. He was one of the associates of Andrew Carnegie in the development of the steel industry. D. 11 May 1934.

CORFE CASTLE, a castle in Dorsetshire, England, now in ruins, standing a little north of a small town, to which it gives its name, and with which it is connected by a bridge of four arches. It was built by King Edgar in the 10th century and at its gates his son Edward the Martyr was murdered in 979. It was the occasional residence of King John, and was for some time the prison of Edward II. During the great civil war it was heroically defended against the parliamentarian forces by Lady Bankes. It was subsequently taken by Fairfax through the treachery of an officer of the garrison, when it was demolished, 1646. Consult Bond, T., 'History and Description of Corfe Castle' (London and Bournemouth 1883).

CORFIELD, William Henry, English sanitarian: b. Shrewsbury, England, 14 Dec. 1843; d. Marstrand, Sweden, 26 Aug. 1903. He was educated at University College, London, and in the medical schools of Paris and Lyons, and was the first professor of hygiene appointed in University College, London. He published 'A Digest of Facts Relating to the Treatment and Utilization of Sewage' (1870); 'Lectures on Water Supply, Sewerage and Sewage Utilization' (1875); 'Laws of Health' (9th ed.); 'Dwelling Houses: Their Sanitary Construction and Arrangements' (4th ed., 1898); 'Disease and Defective House Sanitation' (1896).

CORFU, kôr-foo′ (anciently CORCYRA), Greece, island in the Mediterranean, the most northerly and the largest of the Ionian Islands, at the mouth of the Adriatic, near the coast of Albania, about 40 miles long, and from 15 to 20 wide; square miles, 431. The surface rises in the north at one point to the height of 3,000 feet, but the south portion is low. The scenery is beautiful, the climate pleasant and healthful, save for malaria in the centre and in the south, and the soil is fertile. Oranges, citrons, grapes, honey, wax, olives and oil are abundant. Salt is also produced in some quantity. The ancient name of the island was Drepane. A Corinthian colony settled in the island in the 8th century B.C., taking it from the Illyrian inhabitants. Corcyra's quarrel with Corinth was one of the immediate causes of the Peloponnesian War. The Venetians possessed Corfu from 1386 to 1797, making it a Christian bulwark against the Turks. The British held it from 1815 to 1864. Pop. 106,251. Corfu, the capital, is finely situated on the eastern coast on a promontory which terminates in a huge isolated rock crowned by the citadel; the streets are Italian in style. The chief edifices are the cathedral, government palace and Ionian Academy. There is a good harbor and considerable trade. It is the seat of a Greek archbishop and of a Catholic bishop. Consult Riemann, 'Corfou' (Paris 1879); Partsch, 'Die Insel Korfu' (Gotha 1887); Schmidt, 'Korkyräische Studien' (Leipzig 1890). Pop. 32,221.

CORIANDER, a plant, *Coriandrum sativum,* of the parsley family, native of southern Europe but sometimes established as a weed in North America. It is an annual with finely divided leaves and small white flowers. It is commonly cultivated for the «seeds» (fruits), which are used in flavoring pastries, confectionery and liquors.

CORIGLIANO CALABRO, kō-rē-lyä′nō ka-lä′brō, Italy, city in the province of Cosenza, four miles from the Gulf of Taranto and 70 miles southwest of Taranto. It has a castle and an aqueduct, and markets a high quality of manna from the ash trees of the surrounding country, as well as some oil. It was destroyed in 1806 by the French. Pop. 16,338.

CORINNA, Greek lyric poetess of Tanagra, in Bœotia. She was contemporary with Pindar, whom she is said to have conquered five times at musical contests, and therefore her image crowned with the chaplet of victory was placed in the gymnasium of Tanagra. According to Pausanias, who relates this fact, she was so beautiful that her charms may have influenced in some degree the opinion of the judges. Of the numerous poems which the ancients ascribed to her, only a few fragments have come down to us. Her poems were all in the Bœotian dialect. They have been collected by Bergk in 'Poetae Lyrici Graeci' (4th ed., 1878), and by Schneidewin in 'Delectus Poetarum Græcorum' (-839). Madame de Stael has given the name of Corinne to the heroine of one of her novels. In 1907 a papyrus was found of the 2d century A.D. on which were considerable remains of two poems attributed to Corinna. Consult 'The Year's Work in Classical Studies' (for 1907); Edmonds, 'New Fragments of Corinna' (1910).

CORINNE. 'Corinne' (1806) was the crowning point of Madame de Staël's literary career. In it her ideals find their most complete expression. By it, pre-eminently, and by her 'Germany,' in the words of Faguet, «she sowed the century with fertile ideas and gave French poetry as it were a new soul.» It is a book of self-interpretation. The heroine is herself, and is the only living character in a story whose plot, though easy and graceful, is of no special value. Corinne, of mingled Italian and English blood, has gone from England to Rome to seek psychic emancipation in a freer artistic life than English conventions admitted. With admirable art the spirit of the two nations is contrasted, unreckoning idealism with self-satisfied calculation, passion with cant, nature with respectability, fame with wealth and ease. To Corinne as to Coleridge, all thoughts, passions, delights are but ministers of love. Glory without love is only «the bright shroud of happiness,» conscious intellectual superiority rather a hardship than a boon. Yet a vision of happiness seemed always beckoning her on; and this vision made of 'Corinne,' for a whole generation of romantic spirits, a breviary of generous passion and of ideal love, none the less because the heroine dies at last, abandoning her dignity to her love, a victim to social conventionality. Here a new range of emotions gained recognition in the evolution of fiction. The artistic and musical novels of the next generation, the Teverino's and the Consuelo's, had in 'Corinne' their inspiration and exemplar. It showed, too, as no novel before it had done,

how description of nature might be made to reflect and interpret the psychic moods of its characters. There are four English translations.

BENJAMIN W. WELLS,

CORINTH, Greece, a celebrated city upon the isthmus of the same name. It was renowned among the cities of Greece, commanded by its advantageous position a most important transit trade, and possessed all the splendor which wealth and luxury could create; while its citadel, the Acrocorinthus, rendered it one of the strongest fortresses of Greece. Only a few ruins remain to attest its ancient magnificence. Of the three ancient harbors the western harbor, Lechæum, on the Gulf of Corinth, is choked with sand, as is the eastern harbor, Kekhries (ancient Cenchreæ), on the Saronic Gulf. These were anciently the chief harbors of Corinth. The shallow harbor Schœnos, now Kalamaki, at the eastern entrance of the canal across the isthmus, is used to some extent. There is still a wretched village on the site of ancient Corinth. The American School of Classical studies at Athens began excavations in 1896 on the site of ancient Corinth. Few works of art were found, but the sites of the theatre, the fountains of Pirene and Glauce, the road to Lechæum, the Propylæa and the Agora were determined. In this way a basis was furnished for identifying the topography of the ancient city from the detailed description given by Pausanias. New Corinth (Nea Korinthos) stands about three miles to the northeast on the coast of the gulf, on the railway from Athens to Patras. It is a small town built since 1858, is the capital of the eparchy of Argolis and Corinth, and the seat of an archbishop. It has a harbor and custom-house. Oil, corn, currants, honey and silk are among its principal exports. The Corinth Ship Canal was opened in 1893. The town was destroyed by an earthquake in 1928.

In ancient Corinth great exchange of Asiatic and Italian goods took place. The duty paid on these goods afforded a great revenue to the state; and the citizens accumulated such wealth, that Corinth became one of the most magnificent, but at the same time most voluptuous, cities of Greece. Aphrodite was the goddess of the city, and courtesans were her priestesses, to whom recourse was often had, that they might implore the protection of the goddess in times of public danger; and a certain number of new priestesses were consecrated to her at the commencement of important enterprises. Lais and several other females of the same profession were distinguished by their great accomplishments and beauty, and the high price which they set on their charms; hence the old proverb, *Non cuivis homini contingit adire Corinthum,* that is, «It isn't everyone that can afford to go to Corinth.» The virtuous women celebrated a feast to Aphrodite apart from the others.

The mythical Sisyphus was the founder of the Æolian dynasty, which is represented as the first that ruled in Corinth. It was conquered by the Heraclidæ, and Corinth was subsequently ruled by an oligarchy called the Bacchidæ, in whose time the colonies of Syracuse and Corcyra were founded. This was overthrown by Cypselus in 657 B.C. Periander was the next ruler. Corinth took a prominent part in the development of Greek colonization and was long a great naval power. In the sequel Corinth became the head of the Achæan League, and was conquered and destroyed by the Consul Mummius, 146 B.C. Julius Cæsar, about a hundred years later, rebuilt it; but its commerce could not be restored; the productions of the East now took the road to Rome. A Christian community sprang up in the city under Paul's ministrations, and to it he addressed two letters. The Venetians received the place from a Greek emperor; Mohammed II took it from them in 1458; the Venetians recovered it in 1687, and fortified the Acrocorinthus again; but the Turks, under Ali Comourgi, celebrated in Byron's 'Siege of Corinth,' took it anew in 1715, and retained it until Greece became independent. It was reduced to ashes during the Revolutionary War, and again ruined by an earthquake in 1858. Against any enemy invading the Morea from the north, Corinth and its citadel were formerly of the highest military importance, and as a fortified post it continued of importance to modern times. But by the present Greek government it has been neglected. Consult Curtius, E., 'Peloponnesos' (Gotha 1852); **American School of Classical Studies at Athens, 'Corinth'; O'Neill, J. G., 'Ancient Corinth' (pt. 1, 1930).**

CORINTH, Miss., seat of Alcorn County, near the Tennessee line; alt. 456 feet; on the Mobile and Ohio, the Southern and the Illinois Central railroads; an old railway and industrial center with dairy, machinery, cottonseed, lumber, and brick interests. Government is by mayor and council. Pop. (1940) 7,818. See CORINTH, ADVANCE ON.

CORINTH, N. Y., village in Saratoga County, alt. 637 feet, on the Hudson River (here not navigable) and the Delaware and Hudson Railroad, 17m. E. of Saratoga. It has paper mills. Pop. (1940) 3,054.

CORINTH, Advance on (30 April–30 May 1862), **and Battle of** (3–4 Oct. 1862). Corinth, Miss., an important strategical point, was early occupied by the Confederates. It was the objective point of General Halleck's campaign, for which, early in April 1862, he was concentrating Grant's and Buell's armies at Pittsburg Landing, on the Tennessee River. On 3 April Gen. A. Sidney Johnston marched from Corinth with 40,000 men to strike and crush Grant before Buell could join him; surprised him on the morning of the sixth, at Shiloh; and after a severe fight drove him back to the river, where he was joined by Buell's advance division. Johnston was killed during the battle, and was succeeded by General Beauregard. Grant and Buell renewed the battle on the seventh; Beauregard was defeated, and led his army back to Corinth, having lost 10,000 men. General Halleck joined the army at Shiloh, 11 April, assumed command, drew reinforcements from every direction, and at the end of the month had 110,000 men. Grant was second in command. On 30 April the movement began on Corinth, 27 miles distant, held by Beauregard with about 50,000 men, his army having been reinforced. Early in May Halleck began to throw up elaborate works. It was a siege from start to finish, the army entrenching from the Tennessee River to Corinth. On 9 May occurred an engagement in which the

Union loss was about 180 killed and wounded; the Confederate loss about 160. Halleck continued his slow approaches, gradually gaining ground, and 28 May he was within a mile of Beauregard's main line. On the morning of the 30th it was discovered that Beauregard had made a clean retreat. At Baldwyn, 31 miles from Corinth, he remained until 7 June, when he fell back to Tupelo, 52 miles from Corinth. Halleck occupied Corinth on 30 May, and Gen. Gordon Granger's cavalry, supported by 50,000 infantry, followed Beauregard as far as Baldwyn and Guntown, and here the campaign for Corinth ended. The loss of Corinth was followed by the fall of Fort Pillow and Memphis and the opening of the Mississippi down to Vicksburg.

On 1 Oct. 1862, General Grant, in command of the Union army operating in West Tennessee and northern Mississippi, had about 48,000 effective men. Gen. Earl Van Dorn, commanding the Confederates in Mississippi, believing that a successful attack on Corinth would expel Grant from West Tennessee, concentrated Lovell's division of his own army, with the two divisions of Gen. Sterling Price's army at Ripley, 30 miles southwest of Corinth, 28 September. Next day he marched north, and arrived at 10 o'clock on the morning of 3 October, three miles northwest of Corinth, where he formed his army for attack. He had about 22,000 men. Rosecrans had been warned, and had made dispositions for the attack. In a severe action that day Van Dorn gained two miles of ground and captured two guns. The main works defending the town were close to it, and consisted of a series of heavily armed redoubts, connected by rifle-pits or breastworks. By 9 o'clock that night Rosecrans had formed his lines for the next morning's battle. It was after 9 o'clock of a still, intensely hot day, before Van Dorn attacked. The battle, which was fought with fury on both sides, did not exceed an hour in duration, and by noon Van Dorn's army, Lovell's division covering the rear, was in full retreat, from one of the most sanguinary fields of the war. Gen. Sterling Price, in his report, says: "The history of this war contains no bloodier page, perhaps, than that which will record this fiercely contested battle." At night Van Dorn halted at Chewalla, six miles from the field, next morning hastening his march for Pocahontas to retire by the way he had come. After fighting at Davis' Bridge over Hatchie River, in which he inflicted upon the Federals a loss of 539 killed and wounded, and himself lost 127 killed and wounded, 420 prisoners, and four guns, Van Dorn crossed the Hatchie at Crum's Mill, six miles south, and took the road to Ripley, thence to Holly Springs.

The Union loss at Corinth was 355 killed, 1,841 wounded and 324 missing; an aggregate of 2,520. Rosecrans says he buried 1,423 Confederates, but the Confederate reports show a loss of 505 killed, 2,150 wounded and 2,183 missing; an aggregate of 4,838. Deducting the loss at Davis' Bridge (127 killed and wounded, and 420 prisoners), the Confederate loss at Corinth was 2,528 killed and wounded and 1,763 missing. Consult 'Official Records' (Vols. X and XVII); Grant, 'Personal Memoirs'; Sherman, 'Memoirs'; Greene, 'The Mississippi'; 'Battles and Leaders of the Civil War' (Vol. II); Roman, 'Military Operations of General Beauregard' (Vol. II); Force, 'From Fort Henry to Corinth.'

E. A. CARMAN.

CORINTH, Gulf of, a beautiful inlet of the Mediterranean, about 80 miles long, between the Peloponnesus and northern Greece, having the Isthmus of Corinth closing it in on the east. It is better known as the Gulf of Lepanto. See LEPANTO, BATTLE OF.

CORINTH, Isthmus of, an isthmus connecting the Morea (Peloponnesus) with northern Greece. It varies in width from four to eight miles. A canal, about four miles long, was constructed across the isthmus in 1882–93, which enables vessels to sail from the Archipelago to the Adriatic without rounding Cape Matapan. See CANALS; SHIP CANALS.

CORINTHIAN ORDER, that order of Grecian architecture of which the most characteristic feature is the capital of the column, which is adorned with beautifully carved acanthus leaves, but varies considerably in minor details. The column is generally fluted, with a fillet between the flutings, and stands upon a base. The entablature is variously decorated, especially the cornice; the frieze may be quite plain, or sculptured with foliage and animals. The Corinthian order was not very common in Greece before the time of Alexander the Great. Among the Romans it was much employed.

CORINTHIANS, Epistles of Paul to the. These New Testament letters form only a part of the correspondence known to have passed between the apostle Paul and the church of Corinth. The circumstances that called them forth and dictated their contents were of crucial importance in the early life of that church and the letters can be studied to best advantage in the light of these circumstances. It was probably early in the year 50 A.D. that Paul the missionary and apostle arrived in Corinth, the largest, wealthiest and most dissolute city of Greece and the capital of the Roman province of Achaia. Here the missionary efforts of Paul and his companions soon resulted in the formation of a flourishing Christian church in whose membership all classes of this truly cosmopolitan city were represented, although the majority were of lowly station (cf. Acts xviii, 1 ff.; 1 Cor. i, 26 f.). Paul remained with the infant church about a year and a half, leaving in the fall of 51 A.D. soon after the arrival of the new proconsul Gallio (Acts xviii, 12–18). Some time after Paul's departure Apollos, an eloquent Alexandrian Jewish-Christian visited Corinth and lent his effective aid in building up the church there (Acts xviii, 24; xix, 1). After Apollos' return to Ephesus, the church of Corinth began to be disturbed by various troubles, all due generally to the fact that the membership was quite varied in character, comprising many whose experience of Christianity was brief or only superficial. Party-strife broke out (1 Cor. i, 11 ff.), Paul's apostolic authority was even questioned by some (1 Cor. iv), and one or more cases of immorality had occurred with no censure from the church as a whole (1 Cor. v). In addition confusion of thought regarding various matters of Christian faith and practice was becoming apparent. Meanwhile Paul was at Ephesus (52–54 A.D.) busily engaged in developing a large and far-reaching

missionary movement from that metropolis as a centre.

While engaged in this work, and apparently all unmindful of the troubles developing in the Corinthian church, Paul sent Titus, one of his most trusted assistants, from Ephesus to Corinth to lay before the church there his plan to collect from his Gentile churches a substantial offering for the poor Christian brethren of the old mother-church of Jerusalem (2 Cor. viii, 6, 10 f., 16 ff.; ix, 1 ff.). Titus was well received at Corinth and the church readily promised to contribute to the proposed collection. It is likely, however, that Titus noticed that all was not well with the church and so reported to Paul on his return to Ephesus. This moved Paul to write a letter, now lost, to the Corinthian church in which he urged them to take prompt measures in regard to the case or cases of immorality in their midst (cf. 1 Cor. v, 9). The effect of the letter was, however, to arouse a spirit of bitter hostility against Paul on the part of the guilty ones and their friends, who now began to spread malicious reports concerning Paul amongst the membership of the church, many of whom had been converted after Paul's departure and therefore had had no personal contact with him. This letter was written sometime in 53 A.D., upwards of two years after Paul had left Corinth.

All unaware of the extent of the disaffection toward himself Paul had also arranged to have Timothy, one of his missionary co-workers, call at Corinth in the course of an extended visitation of the churches of Macedonia and Achaia (cf. 1 Cor. xvi, 10 f.). But before Timothy arrived at Corinth a deputation of leading members of the church there, bearing with them also a letter from some portion of the membership of the church, had left Corinth for Ephesus to inform Paul of the whole situation and get the benefit of his counsel (1 Cor. xvi, 17 ff.; vii, 1). On the basis of all the information he now possessed from these and other sources (cf. 1 Cor. i, 11) Paul wrote the letter now known as the First Epistle to the Corinthians (in reality the *second* letter he is known to have written this church) in which he sought to deal fully with all the more important problems then facing the church of Corinth. In all probability Paul sent this letter by the deputation on their return. The date of the letter can be fixed approximately as late in the year 53 A.D. When Paul wrote 1 Corinthians he felt that he possessed the confidence and affection of the church-membership as a whole, although he was aware that the attitude of some was not cordial and that it was necessary to speak plainly in rebuking certain errors in which the church as a whole shared. Like most of Paul's letters this is a *letter,* not a treatise, a message directed toward a concrete situation, dealing with the actual problems of the day and intended to be read and understood by the plain, and not especially learned people of the church as then constituted. Read as such a message it is full of living interest, but if read as an abstract doctrinal treatise it cannot fail of being misunderstood.

After the usual introductory section (i, 1–9) Paul first devotes his attention to the party-strife in the church (i, 10–iv, 21). In dealing with this he points out that the church is the church of *Christ,* not of Paul or of Peter or of any other individual, and being founded upon the message of the Cross it is not based on a theory emanating from mere human wisdom; hence all party-strife and boasting is entirely out of place. His argument throughout was intended to counteract the tendency, evidently present in the church, to view the Christian faith as the product of human wisdom or theory and not as something revealed to man in his ignorance to save him. Paul passes next to advice and rebuke in reference to the offenses against Christian morality of which some had been guilty (v–vi). Then, in answer probably to written questions brought by the delegation, he discusses various aspects of the question of marriage (vii, 1–40) and also the important question as to how a Christian should regard the eating of meat that had been, in one way or another, offered to an idol (viii, 1–xi, 1). Paul's argument here involved reference to several related questions, especially the expediency of yielding one's rights in consideration of others less firmly established in the faith. Then Paul takes up the large question of the proper order and behavior in the public services of the church, criticizing the church's conduct in three particulars, (1) that some of the women prayed in public with head unveiled (xi, 2–16), (2) that there was unbecoming disorder in the observance of the Lord's Supper (xi, 17–34), and (3) that there was an unwise and unedifying use of their various spiritual gifts (xii, 1–xiv, 40). The beautiful description of love as the *way* (ch. xiii) is an integral part of this discussion. Finally, the mooted question of the nature of the resurrection body is taken up and answered at length (ch. xv). The remainder of the letter is devoted to information as to his plans and other personal matters.

It is possible that it was while Paul was writing this splendid letter that Timothy arrived in Corinth only to find that the opposition to Paul in the church there had reached a violent stage. For the moment it seemed as though the church had turned completely against him and that his influence over it was entirely lost. Timothy could do nothing and returned to Paul with a most discouraging report, reaching Ephesus after 1 Corinthians had been sent. Apparently also the return of the delegation with the message contained in 1 Corinthians was, for the moment at least, of no effect. In consequence of Timothy's report Paul at once made a hasty, but painful and ineffectual visit to his rebellious church, returning to Ephesus in great sorrow and anxiety, although not altogether hopeless (2 Cor. xii, 14, xiii, 1f.). He now had recourse to Titus, whose earlier mission to Corinth had been so successful, sending him with a letter, written in great sorrow of remonstrance and appeal. The greater part of this letter is probably preserved in the latter portion of the so-called Second Epistle to the Corinthians, namely in 2 Cor. x–xiii, 10. Such seems to be the only satisfactory solution of the remarkable difference between 2 Cor. i-ix, so full of joyful confidence and thankfulness, and chapters x–xiii, so full of pain, anxiety, apology and explanation. It is this sorrowful letter that is referred to in 2 Cor. ii, 3 f. and vii, 8–12. It was written probably early in 54 A.D. about the time of the disturbance in Ephesus caused by Demetrius (cf. Acts xix, 21–40). In this brief letter Paul first replied to the charge that

he was weak and forceless (x, 1–18), then defended himself for his apparent self-glorification, pleading his special relation to them and showing that in reality he was only glorying in his weakness for it was in reality God's power and not his own that he had in him (xi, 1–xii, 10). He was compelled thus to speak (xi, 11–18) and when he should come to them again, the *third* time, they would know how strong his position was (xii, 19–xiii, 10).

Soon after Titus' departure for Corinth with this message Paul closed his work in Ephesus (June 54 A.D.) in order to make a tour of his Macedonian churches and then to pay a visit to Corinth in case conditions there became more favorable. It was probably at Philippi that Titus rejoined Paul, who had been anxiously impatient to hear from him (cf. 2 Cor. ii, 12), and brought the cheering and comforting news that the church of Corinth had repented of its errors and disloyalty and was fully prepared to follow the Apostle's advice and would be glad to see him again. Out of great joy and thankfulness Paul now wrote his *fourth* letter to the Corinthians, which we possess as 2 Cor. i–ix. The greater part of this letter (chs. i–vii) is devoted to the happy subject of the reconciliation that had been brought about through the efforts of Titus. These chapters do not reveal any carefully worked out plan. They are profoundly emotional and personal rather than deliberately didactic. For example, the thread of thought at ii, 13 is suddenly broken off, as the full significance of Titus' success impressed itself on Paul, not to be resumed until vii, 5. But in spite of this lack of logical sequence these chapters are among the richest in spiritual truth of all the Pauline letters. Here the heart of the great apostle is laid bare and the depth and sincerity of his spiritual experience is disclosed. The latter part of the letter (chs. viii and ix) is devoted to urging the Corinthians to contribute promptly and heartily to the collection for the poor saints in Jerusalem. They had promised to do this the year previous and now, as he was sending Titus back to them with this letter, he urges them to have it all ready for him (Paul) to take it with him to Jerusalem as soon as possible after his expected visit to Corinth, which expectation was realized as we learn from Acts xx, 2.

It should be said that the view adopted above as to the composite character of 2 Corinthians is not as yet generally accepted although it is receiving increasing support. To the writer it is the only theory that satisfactorily explains the references in 2 Cor. ii, 3 f. and vii, 8–12 to a sorrowful letter and also the marked difference in tone between 2 Cor. i–ix and x–xiii.

EDWARD E. NOURSE,
Late Professor of Biblical Theology, Hartford Theological Seminary.

CORINTHIANS, Third Epistle of the, an apocryphal epistle or letter, which like one said to have been sent from the Corinthians to Saint Paul, were both in Armenian. Apocryphal letters or epistles made their appearance at a very early period after the death of the apostles. See APOCRYPHA.

CORINTO, kō-rēn'tō, Nicaragua, in the department of Chinandega, and the principal port of entry on the Pacific coast of the republic. A railroad, owned and operated by the government, connects it with all the principal towns of the republic through to Granada. There are four regular lines of steamships which touch at Corinto, carrying passengers, mail and general cargo, and navigating the Pacific from North to South America. Owing to the intense heat and unhealthfulness of the place, very few people live there, except the government employees, steamship agents, and those employed on the railway and wharves. A «convention of peace and obligatory arbitration» was signed here 20 Jan. 1902, by plenipotentiaries of the governments of Nicaragua, Costa Rica, Salvador and Honduras. It is the residence of a United States vice-consul. Pop. 2,307.

CORIOLANUS, Gaius Marcius, Roman hero, called Coriolanus because the city of Corioli, the capital of the kingdom of the Volsci, was taken almost solely by his exertions. Coriolanus became very unpopular when, during the famine which prevailed in Rome 490 B.C., he proposed to distribute the provisions obtained from Sicily among the plebeians only on condition that they would agree that the tribuneship should be abolished. Banished for this cause, Coriolanus, resolving to revenge himself upon his country, went to the Volsci and prevailed upon them to go to war with Rome before the expiration of the truce. He himself was joined with Attius Tullius in the command of their army, which immediately made itself master of the cities of Latium, and the Volscian camp was pitched in sight of Rome before troops could be raised for the defense of the city. The envoys sent by the Senate returned with the answer, that Rome could purchase peace only by the surrender of the territory taken from the Volsci. A company of Roman matrons, headed by Veturia, the mother, and Volumnia, the wife of Coriolanus, at length subdued his resolution and he withdrew his army, and lived among the Volsci until his death. On the spot where he yielded to his mother's words a temple was dedicated to Fortuna Muliebris and Valeria was its first priestess. Shakespeare, in his play of 'Coriolanus,' calls the hero's wife Virgilia, his mother Volumnia and the Volscian leader Tullus Aufidius. Consult Smith, 'Dictionary of Greek and Roman Biography and Mythology.'

CORIOLANUS, probably the latest of Shakespeare's Roman plays, dates from about 1609. Like 'Julius Cæsar' and 'Antony and Cleopatra,' its plot is derived from Sir Thomas

North's translation of Plutarch's 'Lives' (first published in 1579), of which it makes on the whole an even closer use than the other two plays. About 550 lines of North's 'Life of Coriolanus' are woven into the drama, often — as in the case of the hero's great speech to Aufidius at Antium (IV, v, 71 ff.) and Volumnia's appeal for Rome (V, iii, 94 ff.) — with only the slightest verbal change. If the accepted date, as given above, is correct, 'Coriolanus' may be presumed to be the last of all Shakespeare's tragedies. It was not printed before the appearance of the first folio in 1623, and there occupies the first place in the group of tragedies, a position analogous to that of 'The Tempest' at the head of the comedies. It is one of the longest of Shakespeare's plays (only 'Richard III,' 'Hamlet,' and 'Cymbeline' cover a greater number of pages in the folio), and it is one of the most thoughtful. Without essentially changing Plutarch's story, Shakespeare has vastly elaborated the basic theme of the conflict between plebeian and patrician, with the result that this play remains his most ambitious effort at interpreting social theory. Like Plutarch, and like the Elizabethans generally, Shakespeare sympathizes with the claims of the aristocrat in the commonwealth, but he here reflects more justly than elsewhere both the force and weakness of democracy. This aspect of the play has naturally tempted discussion. In one of his most characteristic and provocative essays ('Characters of Shakespeare's Plays,' 1817) William Hazlitt expounded 'Coriolanus' as an illustration of the uncompromising aristocracy of poetry. On the stage, 'Coriolanus' has had an eventful history. During the latter part of the 17th and through the 18th century various revised versions held the stage. The 19th century saw the gradual restoration of the original text. John Philip Kemble was famous in the play, along with his sister, Mrs. Siddons, and selected it for his farewell performance in 1817. The American actor Edwin Forrest similarly chose the rôle of Coriolanus as that in which to be immortalized in a statue.

TUCKER BROOKE,
Assistant Professor of English, Yale University.

CORK, First Earl of. See BOYLE, RICHARD.

CORK, Ireland, a maritime county, province of Munster, having Saint George's Channel south, County Limerick north, Kerry west, Waterford and Tipperary east. Extreme length, east to west, 110 miles; extreme breadth, 70 miles; area, 2,890 square miles. The coast is indented with numerous bays and inlets, of which the more important are the bays of Bantry, Dunmanus, Long Island, and Clonakilty, Kinsale and Cork harbors, and is serrated with headlands and promontories. Off the coast lie the islands of Clear, Whiddy, Dursey, Bear and several smaller. The county is watered by the Bandon, Lee and Blackwater, and numerous smaller streams. The county is rich in coal, limestone and sandstone, and some iron is mined. Pop. (1936) 274,783.

CORK, Ireland, city, capital of the county of Cork, situated on the river Lee, 15 miles from the sea and 165 miles southwest of Dublin. Besides an upper harbor at the city itself, and quays of over four miles in length, there is a lower harbor at Cobh (Queenstown), 11 miles below. The entrance, deep and narrow, is strongly fortified on each side. Cork is the third city in Ireland, and exports great quantities of grain, butter, bacon, eggs and live stock. The principal industries are tanning, distilling, brewing and the making of tweeds and linens. There are also iron foundries and yards for the building of iron ships. The principal buildings are the Protestant and Roman Catholic cathedrals, exchange, custom-house, chamber of commerce, courthouse, Queen's College, etc. There is a naval dockyard at Haulbowline, an island within Cork harbor. Cork dates from a religious settlement in 622 and from a Danish trading settlement of the 11th century. Pop. county borough (1936) 80,713.

CORK, the outer bark of a species of oak *(Quercus suber)* which grows in forests adjacent to the Mediterranean Sea. It is distinguished by the cellular texture of its bark, and its evergreen leaves which are oblong, somewhat oval, downy underneath, and waved. Although the cork oak grows in other parts of the world, only in the Mediterranean climate does it produce a bark that can be classified as good commercial cork. Therefore, the world's supply is limited to the Mediterranean countries in general, and to Spain, Portugal, and Algeria, more particularly. In these areas more than 80 per cent of the world's output is produced, the remaining portion being distributed among French Morocco, southern France, Italy, Tunisia, and Spanish Morocco.

The cork oak grows in forests in the company mostly of firs and evergreen oaks, but in a part of Tunisia there exist forests consisting entirely of cork oaks. The bark of these Tunisian forests is said to be of an unusually excellent quality. Ordinarily the cork oak grows to a height of 25 to 50 feet, although some have been reported to reach a height of 150 feet; its diameter at maturity may measure as much as four feet. The first stripping of the bark takes place when the trees are from 12 to 20 years old and have a diameter of four to five inches; this does not harm the tree, however, so long as the inner bark or skin is not injured. As a matter of fact, the removal of the outer bark is beneficial, rather than harmful; for the unscarred inner bark immediately undertakes the formation of a new covering of better quality. The product of this first stripping is of a low grade, called virgin cork, which is ground for cork insulation and composition cork products. After 8 or 10 years, the outer bark is again removed; and while of much better quality than the virgin bark, it is not so fine in texture as future yields, which follow every 8 or 10 years until the tree is a hundred years old, or more. All this stripping takes place between May and August, depending on the locality.

In the collecting of cork, it is customary to slit it with a knife at certain distances, in a perpendicular direction from the top of the tree trunk to the bottom; and to make two incisions across, one near the top and other near the base of the trunk. For the purpose of stripping off the bark, a curved knife with a handle at each end is used. Sometimes it is stripped in pieces the whole length of the trunk, and sometimes in shorter pieces, cross cuts being made at certain intervals. In some instances, after the perpendicular and transverse incisions are made, the cork is left upon the trees until, by the growth

of the new bark beneath, it becomes sufficiently loose to be removed by hand. As the bark is removed, it is dried out and weighed, then taken to a boiling station, where it is seasoned for a few weeks, sorted as to quality and thickness, and finally boiled to loosen the grit and dirt, so that it may be scraped. The boiling also removes the tannic acid and renders the bark soft and pliable for flattening.

The uses of cork were well known to the ancients, and were nearly the same as those to which it is now applied, at least in general principles. It is generally agreed that cork was in use at least 2,000 years ago, since Pliny mentions cork items in his writings during the first century A.D. It was not until about 16 centuries later, however, that the cork industry became recognized as such; the occasion was the introduction of the glass bottle, with its companion, the cork stopper. The original factories fabricating this material were located in Spain and Portugal in close proximity to the cork forests; and although the manufacture of cork stoppers was subsequently established in most industrial countries, the Iberian industry still produces a large share of the world output. The cork stopper, however, is only one of the many modern uses for cork. A list of cork products in everyday use would include the following: disks, washers, floats, bungs, life rings, balls, mats, handle grips, gaskets, bobbers, life preservers, shoe insoles, polishing disks, cork paper, tropical helmets, rafts, sound insulation, temperature-control insulation, floor tiles, roof tiles, sweat bands, lining for hats, cigarette tips, shell-case wads, and linoleum. While many of these products are produced in various countries, all of them are manufactured in the United States from imported material, since the cork oak does not grow in the United States in commercial quantities. Various attempts have been made since 1858 to establish this forest industry—the most successful experiments having been carried on in California, where about 1,500 trees of all ages have been planted under varying conditions—but no sizable satisfactory yields have been reported.

Nevertheless, despite the absence of domestic raw material, the manufacture of cork products in the United States has become an important industry. Some 35 plants employ more than 3,000 persons yearly in the production of cork articles valued at about $18,000,000. Cork products are usually classed in three general categories—stoppers, insulation materials, and specialties. To supply this industry with the necessary raw material, the United States imports annually an average of 215 million pounds of cork bark, wood, waste, and shavings. Portugal, the leading exporter of these items, supplies about 60 per cent of the imports, Algeria 22 per cent, and Spain 12 per cent. France, Great Britain, Germany and the United States normally receive about 65 per cent of the total production of cork.

Most of the world's cork supplies are under the domination of three governments—Portugal, Spain, and France—each of which controls in large part both production and trade. This fact is of importance to the United States which relies upon cork as a material essential to its national defense in wartime, and which depends, for its supply of cork, entirely upon transatlantic shipping.

CORKITE, a lead ore of minor importance consisting of phosphate and arsenate of lead and ferric sulphate. It occurs in ores of Beaver County, Utah.

CORLEONE, kōr-lā-ō'na, Sicily, town in the province of Palermo, and 22 miles south of the city of Palermo, near the source of the Belici. It is well built, has several churches and convents, a prison, royal college and some other public edifices. The inhabitants are principally engaged in agriculture. The ancient Korliun was founded by the Saracens and colonized with Lombards by Frederick II in 1237. Pop. 14,900.

CORLISS, George Henry, American inventor: b. Easton, N. Y., 2 June 1817; d. Providence, R. I., 21 Feb. 1888. The construction of stationary steam engines was revolutionized by his improvements and a single engine made by him moved all the machinery in the centennial Exposition of 1876.

CORLISS ENGINE. See STEAM AND STEAM ENGINE.

CORM, or **CORMUS,** in botany, the dilated base of the stems of some plants, as the crocus, cyclamen, etc. It is commonly called bulb or root tuber, but is actually neither.

CORMON, Fernand, French painter: b. Paris, 22 Dec. 1845; d. 1924. He studied under Cabanel, Fromentin and others, and in 1875 he received the Prix de Salon; in 1887 a medal of honor at the Salon of that year; in 1889 the Grand prize at the Paris Exposition, and became an officer in the Legion of Honor. His best-known works are 'The Stone Age' (1884); 'The Victors of Salamis' (1887); other works of his are 'Cain' (1880), and 'The Raising of the Daughter of Jairus.' A series of archæological paintings representative of human development from prehistoric times gave him celebrity, and his portraits have given him a high reputation in that branch of art.

CORMORAN, a Cornish giant in the nursery tale 'Jack, the Giant-killer.'

CORN (from French *corne,* from Lat. *cornu,* a horn, from its horny nature), a hardened and thickened portion of cuticle produced by pressure. Corns are generally found on the outside of the toes, but sometimes between them, on the sides of the foot, or even on the ball. They gradually penetrate deeper into the parts, and sometimes occasion extreme pain. No part of the human body, probably, has been injured so much by our injudicious mode of dress as the feet, which have become, in general, deformed. To this general deformity of the foot belong the corns, produced by the absurd forms of our shoes and boots. They appear at first as small dark points in the hardened skin, and in this state stimulants or escharotics, as nitrate of silver (lunar caustic), are recommended. The corn is to be wet and rubbed with a pencil of the caustic every evening. It is well to have the skin previously softened. If the corn has attained a large size removal by a cutting or ligature will be proper. In all cases

of cutting corns very great precaution is to be observed. The feet ought always to be bathed previously. Mortification has, in many instances, resulted from the neglect of this precaution, and from cutting too deep. An efficacious remedy for corns is the application of glacial acetic acid night and morning. This acid has a peculiarly destructive effect on the epidermis, of which corns are a hypertrophy. Salicylic acid is also an excellent application. A simple and generally very efficacious means of alleviating the pain caused by corns and removing the cause for their growth is the application of a thick adhesive plaster, in the centre of which a hole has been made for the reception of the projecting part.

CORN, grain, such as wheat and barley; maize, or Indian corn; also the plants that yield grain; breadstuff. This is a generic term for all kinds of grain used for making bread, and is applied specifically to the principal breadstuff; in England to wheat, in the United States to Indian corn or maize, and in Scotland frequently to oats. The word is Anglo-Saxon, and occurs in similar forms in the other Teutonic tongues. The words seem to have been used in ancient times as at present, having a different meaning in different countries.

Indian corn, also called maize, is an endogen which grows luxuriantly in warm temperate climates. It belongs to the tribe of *Phalaridæ* of the order of *Gramineæ,* or grasses. It is known in botanical science by the name *Zea mays.* The flowers are monœcious; the male flowers forming a loose panicle at the top of the culm; the female flowers in axillary spikes, enclosed in large, tough spathes, from which only the extremely long styles — in the common species six to eight inches in length — hang out like tufts of feathers or silken tassels. The grains are large, roundish, compressed, naked and arranged in parallel rows along the upright axis of the spike. The long parallel-veined leaves and the stalks are often used as fodder. The common Indian corn is generally believed to be a native of the warmer parts of America, where it was cultivated by the aborigines before the discovery by Columbus; but a representation of the plant found in an ancient Chinese book in the royal library in Paris, and the alleged discovery of some grains of it in the cellars of ancient houses in Athens, have led some to suppose that it is a native also of the East, and has, from a very early period, been cultivated there, and even that it is the «corn» of Scripture; although, on this supposition, it is not easy to account for the subsequent neglect of it until after the discovery of America, since which the spread of its cultivation in the Old World has taken place with a rapidity such as might be expected from its great productiveness and other valuable qualities. Columbus himself took it to Spain. When first introduced into Europe, many supposed it was brought from Asia, and it was frequently known as Turkey corn, Turkey wheat.

Sweet corn is any one of the starch corns, flint, dent or flour corn, that has lost its faculty of converting sugars into starches. It is grown chiefly as a vegetable for table use, although the stover is often harvested as forage for stock. Its culture is most extensive in the vicinity of large cities, where it is grown as a truck crop and in certain regions where it is grown as a canning crop. The principal canning variety is a late corn, Stowell Evergeen. Country Gentleman is also used to a large extent among the canners. In Maine, a corn known as Clark's is used for canning. Hickox and Trucker's Favorite are the principal canning varieties in other regions. In the suburban truck gardens the custom is either to plant early and late corn, or one high-class variety every two weeks. Cory, Crosby, Quincy Market, Country Gentleman and Stowell Evergreen are often planted in the order named.

In 1937 the amount of Indian corn produced in the United States was 2,644,995,000 bushels and in 1920, the record year, 3,208,584,000 bushels. Argentina, Rumania and Mexico are other large corn-producing countries, the crop of Argentina from 1935–37 averaging 241,400 bushels. The average for the world now runs about 4,400,000,000 bushels per year.

CORN CLUBS, organizations promoted in 1916 in the rural districts of the United States, for the purpose of arousing interest in the scientific culture of corn and other agricultural products among the country boys and girls; and to supply wholesome recreational activity for the members. These clubs were founded in connection with the general movement for rural recreation.

CORN-COCKLE *(Agrostemma githago),* a plant of the pink family *(Silenaceæ).* It is an annual, pubescent, often branching herb, from one to three feet tall, distinguished by its large purple flower. Though a native of Europe and western Asia, it is now found in most temperate regions, frequenting grain-fields and waste places. When its seeds become mixed with those of the grain, and are ground with them, it is said to effect and render the grain unwholesome; thus it requires to be separated from the grain by a special kind of sieve. In Germany the seed when ripe and dried is called schwartz-kümmel (black cumin), and is sold for medicinal and domestic purposes.

CORN-CRAKE (that is, «corn crow,» because of its cry), the common name in England of a small rail (*Crex pratensis)* which frequents meadow lands throughout Europe; also called landrail. The name crake is applied to various other birds of the family *Rallidæ,* which differ from the typical rails in having a shorter beak. In the United States the common rail *(Porzana carolina)* and allied species are occasionally so called. They are secretive birds, abundant in reedy swamps, and are much sought by gunners in the fall of the year.

CORN CULTURE. Corn is America's most important crop. It is grown on as great an acreage and has a value greater than that of wheat, oats, barley, rye, and rice combined. It is important not only from an economic standpoint but also because it originated in this hemisphere and has been intimately tied up with the development not only of the United States but the entire Western Hemisphere.

Corn Belt.—The Corn Belt, made up of the States of Iowa, Illinois, Indiana, Ohio, Missouri, Kansas, Nebraska, South Dakota, and Minnesota, is possibly the greatest agricultural

region in the world today. This region, as its name implies, is characterized by the growing of this crop, on which it is primarily dependent. In this area are nearly 150,000,000 acres of the richest land in the world. Each year about one-third of this land is planted to corn.

This discussion of corn growing and factors primarily on the growing of the crop, height of dent or field corn) in the Corn Belt. maturity, are other large and important corn considered tions. One is found in the cotton effect upon total the acreage is large but the yield special qualities, less than 20 bushels to the acre, content and insect with about 40 bushels to the acre real possibilities Belt. Another important corn hybrid seed. in Argentina, where there istics of some corn land similar to the North various agricultural The season for growing is follows: uniformity, the reverse of that in the foliage, easy picking, ing is done in November, approved market quality, corn is harvested in suckering, leafiness, re- there is an area in disease, and high weight sometimes referred to cross Bantam, the outstand- Belt.» There hybrid, is somewhat resistant to that found in the bacterial wilt disease. The Min-

Mexico Agricultural Experiment Station has developed Minhybrid, 301, 401, and 402, smut-resistant hybrids. Some superior qualities in addition to yield, therefore, have been bred into hybrids. Many of these qualities are the result of their close relationship with yielding ability. In but few cases to date have breeders set out deliberately to get these specific characteristics. Hybrids with ability to yield have been the real goal of most breeders.

In 1896 the Illinois Agricultural Experiment Station demonstrated that by selection they could develop types of corn that varied strikingly in certain characteristics. They originated, after two decades of selection, a high-oil strain of corn, carrying over 10 per cent as compared to a low strain with but 2 per cent. Their high-protein strain carried 16 per cent protein as compared with a low-protein strain carrying 6 per cent. They lacked, however, high yielding ability. The intensive selection for one particular characteristic resulted in close breeding and a consequent loss of vigor.

The hybrid vigor theory of breeding, it is hoped, will offer a way out of this dilemma and permit the utilization of inbred strains high in these special qualities. The crossing of certain of these inbred strains should bring about the yielding ability that the open-pollinated strains selected for certain qualities lacked, and increase the chances of producing hybrids of certain superior qualities. Not all hybrids are worth while; some hybrids are much less desirable than the average open-pollinated corn. Hybrids differ markedly in their ability to yield, resist lodging, mature properly, and in other important characteristics.

It is necessary to know a hybrid's special quality characteristics as well as its yielding ability. Most plant breeders are of the opinion that the ultimate solution of many troublesome problems of crop production can be more effectively and cheaply attained by breeding resistant varieties than by using other methods that are merely palliatives.

The Nebraska Agricultural Experiment Station points out that a distinction is made between the adaptation of hybrids and open-pollinated varieties. They state that adaptation of hybrid corn originating from crossed inbred lines is dependent upon component lines and not upon the locality where the seed is produced, as is the case with open-pollinated varieties. All hybrids are not equally good and they also differ widely as to vegetative size and number of days required to mature. After the local adaptation and superiority of any specific hybrid have been established through trial, it is possible to procure this same hybrid with essentially identical characteristics year after year irrespective of where the seed is produced, provided the same parental seed stocks and proper crossing technique have been used. Thus, if the climate and soil conditions are favorable for the production of sound seed, it is immaterial whether the seed of any specific hybrid is produced in the north or south, and whether on unirrigated or irrigated land.

An important factor in the selection of a hybrid variety of corn, formerly not of importance in the case of ordinary open-pollinated varieties, is the great sensitivity of hybrids to fertility conditions. This has been shown strikingly in Illinois, where it was found that the five highest yielding hybrids on the more productive area were 17.5 bushels an acre above the open-pollinated check variety. The same five high yielding strains were only 1.2 bushels better than the open-pollinated variety on the low level of fertility. Good high yielding hybrids that

CORN PRODUCTION BY STATES—10 YEAR AVERAGE —1927–36

were responsive to a high level of fertility seemed to be very sensitive to a lack of that fertility. They found that hybrid strains were markedly superior to the open-pollinated variety when grown on good soil. However, when grown on soil relatively low in fertility they were not greatly superior in yield of sound corn and there were cases in which they were considerably inferior to the adapted open-pollinated corn. Hybrid corns are increasing yields, and at the same time they are requiring growers to pay closer attention than ever before to the selection of sorts to grow.

Basic Soil Needs.—Corn is a rank-growing crop that requires for the best growth high soil fertility. For example, a 40-bushel corn crop takes from the soil 60 pounds of nitrogen, 8 pounds of phosphorus, and 28 pounds of potassium. A method of evaluating soil productivity changes, and particularly the annual fertility and erosion losses from soils in Missouri, has been developed by their Agricultural Experiment Station. The method is based primarily on the annual gain or loss of nitrogen in the surface 7 inches of soil. The station found that the total organic matter and nitrogen content of a silt-loam soil was a guide to crop yields—for each thousand pounds of total nitrogen in the surface 7 inches of an acre, 10 bushels of corn can be expected. In connection with this work the station found in soil studies of virgin and cultivated areas where no erosion occurred that cropping alone reduces the organic matter and nitrogen about 35 per cent. On the other hand, better crop practices have increased yields from 20-30 per cent or have almost compensated for the declining soil productivity.

Only through some systematic method of growing can high yields be maintained. In general, this system requires the use of (1) rotations, (2) barnyard manure, (3) green manure, (4) crop residues, (5) proper tillage, and (6) commercial fertilizers.

Proper crop rotations are basic to successful corn growing. Only on the most unusually rich river bottom soils can corn be grown continuously. On all other types of soil, corn must be grown in some type of rotation if the grower desires to get maximum yields, decrease soil erosion, and damage from insects, diseases, and weeds, and maintain soil fertility. Possibly the most typical rotation including corn is: corn, corn, oats and clover. The amount of corn that is included in a rotation depends almost entirely on the fertility of the soil. Labor requirements, however, might be such that a grower can handle only a given amount of corn each year, as the corn crop requires more hours of labor than most ordinary field crops.

One of the most important jobs connected with corn growing is the spreading of manure. Corn is able to utilize the benefits of barnyard manure as well as, if not better, than, any other crop. The lack of sufficient manure on most Corn Belt farms, however, will eventually create a fertility problem. Generally a ton of manure contains about 10 pounds of nitrogen, two pounds of phosphorus, and 10 pounds of potassium.

Growers should spread all available barnyard manure in the spring, since losses are greater on summer than on winter-stored manure. Each year about a billion tons of manure, valued at $3 a ton, are produced on the farms of the United States, but more than half of its value, or about two billion dollars, is lost due to poor storing and improper handling. Manure has a soil-conserving as well as a fertilizing value and should be applied to crops of high value, such as corn. Manure, particularly when supplemented with a good phosphorus fertilizer, brings the greatest returns. In general, light applications, three or four tons, and not in excess of eight tons per acre, should be made.

Successful corn growing requires as a third step closely following the use of rotations and manure, the plowing under of a green manure crop once in every four years, rather than once in a decade or more, as is the more common practice. There are two types of green manure crops, legumes and non-legumes. Both furnish organic matter, but the latter, of course, do not have the ability to add nitrogen taken from the air by the bacteria on their roots. For corn, possibly the best green manures are the various clovers, like red clover and sweet clover. In drought years heavy crops of clover plowed under before the corn crop sometimes are detrimental to corn yields, as in these instances the soils tend to dry out rapidly, and the corn crop does not have a chance to mature normally. There is much misinformation as to the value of plowing under legume crops. As indicated, legumes have the power of taking nitrogen from the air, and when they are turned under, the nitrogen added is that taken from both the air and the soil, but the portion that is new or really added is that derived from the air. In general, it is assumed that on an average, about two-thirds of the nitrogen in a legume is from the air and one-third from the soil.

All crop residues like straw and cornstalks should be utilized wherever possible. On highly mechanized farms, growers burn cornstalks, because they interfere in the operation of the machinery. They must realize that when cornstalks are burned or removed, considerable organic matter and nitrogen is lost. It is estimated that a ton of cornstalks contains more nitrogen than a ton of manure and four times as much humus. Growers must decide whether it is more advantageous to get rid of these cornstalks or utilize their fertilizing value. In sections where insects like the cornborer are present, of course, cornstalks must be removed and destroyed.

Good tillage for corn requires plowing either in the fall or spring. In the Corn Belt it is found that about one-third of the corn is planted on cornstalk ground, about one-half on small grain stubble, and the remainder on sod ground. In every case, however, plowing is necessary for proper seedbed preparation. Ordinarily five-inch plowing is satisfactory on most soils. Deep plowing is of value only on unusual soil types. Inasmuch as cultivating corn to kill weeds is the most expensive and time-consuming job connected with corn growing, every effort should be made to insure proper tillage, so that weeds will be destroyed before planting, rather than afterwards. This may be done by proper disking and harrowing after plowing and before planting.

For efficient crop production most soils need some fertilizers, but fertilizers alone will not produce a successful corn crop. On many Corn Belt soils phosphate fertilizers give more profitable results than mixed ones. These may be applied either as superphosphate or rock phos-

phate. Special soil types, of course, require specific fertilizers. For example, on peat soils the addition of potassium usually gives results. Fertilizers are (1) broadcast either before the corn crop or on legume and grass seedings, and (2) applied directly in the hill with corn planters that have fertilizer attachments. These attachments distribute the fertilizer in bands about one inch on each side of the seed. Care must be taken so as not to get the fertilizer in contact with the seed and cause poor germination.

Planting.—There are two common methods of planting corn, surface planting and listing. Listed corn is drilled but surface planted corn may be drilled or checked. Corn planting machines are remarkable in their precision. If it is desired to plant three kernels to a hill, an accurately calibrated machine will accomplish this result better than 90 times out of 100, planting two or four kernels the other times. Planters that will plant two, three, or four rows at a time are common. Checked corn is planted in hills usually three and one-half feet apart each way. In the case of drilled corn the rows are usually the same distance apart, but in the rows the kernels are dropped every 10 or 12 inches rather than placed in a hill.

The more common method of planting is checking. Where corn is grown for silage or fodder on clean ground, drilling has some advantages. In general, however, checking gives such an opportunity to control the ordinary weeds in the cornfield that it remains the favored method. On the whole listing is not as common a practice in some of the Corn Belt sections as formerly. In western Kansas and Nebraska, however, it is still looked upon as a method for combatting drought conditions.

Corn production practices change comparatively slowly. Many growers are still growing corn in much the same way as their grandfathers. One important thing that forces changes in procedures is the advancement made in the development of tractors and planting, tillage, and harvesting machinery. The important factors in planting are time, rate, depth and method. Every grower has considerable control over these factors, although time of planting is often dependent upon weather conditions. It is of interest to know that the average date of corn planting for almost the entire country is around 10 May. At this time growers have had an opportunity to prepare the ground and the soil is sufficiently warm and moist to insure prompt germination. There is no sense in planting corn in cold, wet soil.

The rate of planting depends primarily on the purpose for which the corn is to be used, the region in which it is grown, the type of soil, and the variety of corn. In most places three kernels per hill is the standard rate of planting (one bushel of seed will plant about seven acres). The planting of three kernels per hill will produce about two stalks per hill. In this connection it is essential to remember that the uniformity of stand is important. It is necessary to have at least one stalk in every hill if full yields are to be obtained. It is the large skips that bring down yields rapidly. Rates of planting above three kernels per hill usually increase the number of ears but decrease their size, and unless the soil is very fertile, actual yields are not greatly affected.

Many experiments have shown that corn planted about two inches deep is higher yielding than that planted much deeper. Deep planting has nothing to do with the depth of the root system. The corn plant sends out its permanent root system just beneath the surface of the ground. Listing, of course, does get the permanent roots deeper, for this method provides for filling in corn around the plant after it is up.

Cultivation.—Corn cultivation is a slow and tedious job. Ordinarily, a corn grower goes over his crop three times, beginning when the corn is a few inches high and «laying it by» when it is too high for machinery to get through the fields. It has been estimated that for every 100 acres of corn it takes 600 hours of man labor and 1,200 hours of horse labor, and that a distance of nearly 1,000 miles is covered in doing the job.

Many reasons have been given for cultivating, but the main one, and in most cases the only one, is to kill weeds. Therefore, the method of cultivation that does the most effective job of weed-killing is the best. Inasmuch as cultivation is such a big job, and weeds are the main reason for cultivation, it is well for growers to know common cornfield weeds. In the Corn Belt common perennial weeds include wild morning glory, milkweed, quack grass, and Canada thistle. These are the most difficult to get rid of, and often require hand hoeing or some other special method of eradication. Common annual weeds, such as cockleburr, smartweed, foxtail, and ragweed require no more than the ordinary three or four cultivations previously described.

Insects and Diseases.—There are numerous insects and disease pests of corn which at times seriously injure fields in areas of varying extent. The principal insects attacking corn are the corn earworm, *Heliothis armigera* (Hbn.); chinch bug, *Blissus leucopterus* Say; Noctuid cutworms; armyworm, *Cirphis unipuncta* Haw.; grasshoppers, *Melanoplus* spp.; European corn borer, *Pyrausta nubilalis* Hbn. and other Lepidopterous stalk borers; white grubs, *Phyllophaga* spp.; corn rootworms, *Diabrotica* spp.; various wireworms of the family Elateridae; corn root aphid, *Aphis maidi-radicis* (Forbes); corn leaf aphid, *Aphis maidis* Fitch; billbugs, *Calendra* spp.; webworms, *Crambus* spp.; flea beetles, *Chaetocnema* spp.; and various weevils and moths that attack stored corn.

Control measures of these insects are chiefly cultural, such as timely plowing, adjustment of crop rotations, and elimination of weeds or other alternative host plants. Poison bran baits are widely and successfully used for the control of grasshoppers, armyworms and certain species of cutworms. Injury by the chinch bug can be much reduced by dust-mulch or furrow barriers of various kinds to prevent migration of the bugs on foot into the corn from adjacent ripening or dying small grains. The best type of barrier includes the use of a thin line of coal-tar creosote applied on a low ridge to repel the bugs and direct them into postholes dug every 20 or 30 feet along the line. Insects attacking stored corn can be controlled by placing it in tight bins or under airtight tarpaulins and applying certain heavier-than-air fumigants. Some progress is being made in the development of corn varieties possessing more or less resistance to some of its insect pests and diseases. For example, it is known that some varieties of corn are resistant to chinch bug damage. The outstanding variety is "Democrat," or "Champion

White Pearl." This variety of corn, however, is adapted to conditions of the long growing season of the South. There never have been any ordinary varieties of corn in the more northerly sections subject to chinch bug damage that were resistant. Recently, however, hybrid corns have shown chinch bug resistance. It is the hope of corn improvers to make the hybrids of the future not only high-yielding and stiff-stalked, but also resistant to both smut and the second-brood chinch bug.

In some sections birds, rodents and rabbits destroy stems of corn, particularly at planting time. Usually this necessitates replanting.

There is a variety of corn diseases, and doubtless they take an annual toll, but ordinarily they do not cause complete damage to a corn field. The most common disease is corn smut. There are two kinds of smut, the ordinary *Ustilago zea* and another rarer kind found in the Far West known as "head smut," *Sorosporium reilianum.* Corn smut is not poisonous, but it does destroy entire ears and sometimes stalks of corn. Rotation and removal of smut balls before they burst, if practicable, is helpful, but seed treatment such as is employed in the case of small grains, is of no value, since the spores that cause the disease are soil-borne.

Bacterial wilt or Stewart's disease *(Aplanobacter stewarti)* is a common disease of corn, particularly sweet corn, in the Middle Atlantic States and the South. As the name implies, the disease is caused by bacteria, usually carried by a corn flea beetle. Some varieties like Golden Bantam are susceptible to the disease but others such as Golden Cross Bantam (hybrid) are resistant. Yellow streaks on the leaves, wilting and stunting of the stalks and poor ear development are characteristic. Only in certain seasons, those with mild winters, is the disease common in the Corn Belt. The organism is also carried by the seed, but seed treatment is of little value because of the large amount of secondary infection in the summer.

There are a large number of other diseases of corn, usually classified as ear or root rots. These rots are caused by various fungi and bacteria. The most common rots of corn are diplodia and fusarium. Selection of disease-free ears through the seed corn tester and seed treatment with organic mercury dust are the most effective ways of reducing these diseases. Minor diseases of corn are rust and leafspot.

Harvest.—After cultivation, corn requires no attention until harvest time. The crop generally is harvested for (1) fodder, (2) silage, or (3) grain.

YIELD OF DRY MATTER IN CORN AS RAISED IN INDIANA

State of Growth	Corn Plus Cob (Ear)	Stalks, Blades, Husks, etc.—Stover	Entire Corn Plant
Four feet high	.....	.....	7.76
First tassels	.....	.....	23.85
Silks drying, kernels forming	14.56	90.21	48.53
In the milk	43.73	92.41	65.59
In the glaze	74.56	100.00	86.11
Well dented	89.19	101.84	94.87
Ready to shock	100.00	100.00	100.00

Corn fodder is the entire plant, stalk and ears. Small acreages are usually harvested for fodder either by hand or with the corn binder. After cutting, the bundles of stalks are placed in large shocks for curing. In some areas the ears are harvested from these shocks, leaving what is known as "stover," or stalks without ears. This stover is a valuable roughage for all classes of live stock, particularly when cut or shredded by machine.

Possibly the best method of utilizing the entire crop is to put it in the silo. Corn silos are common in the dairy sections, and particularly in areas where roughage like alfalfa is not plentiful. The use of silage dates back to ancient times.

Now, of course, the silo most commonly used is the above-ground type, built of masonry or wood, but in recent years below-ground, or pit, silos have been used, particularly in the drier areas.

Silage can be made from almost any plant that is not poisonous. Corn, however, is better adapted to the making of silage than other common crops. Possibly this is due to its composition, which makes it better adapted for the fermentation process. Some crops contain too much protein, others are deficient in starch, and do not adapt themselves to the making of palatable and nutritious silage like corn. When silage is made several changes are produced—chemical physical, and bacterial which occur over a period of from two to three weeks. If silage is well packed and air is excluded, it will keep indefinitely. Ordinarily an average acre of corn will produce around seven or eight tons of silage. Yields of 15 to 20 tons, however, have been known. To make good silage the corn should be cut in half-inch lengths. Sufficient water should be added to bring the moisture to about 70 per cent. When well preserved, silage should be sweet and free from molds and contain no sharp odors of acid or spoiled butter. Silage is relished by most classes of live stock, particularly cattle and sheep. It is an excellent substitute for hay, requiring about three pounds for one pound of hay.

To measure silage in a circular silo it is necessary to square the diameter of the silo, multiply by .7854 and the depth of the silage. This gives the number of cubic feet, and if this is divided by 40, the number of pounds per cubic foot, one may determine the number of tons of silage.

Wisconsin, which has been the leading silage-producing State for many years, produces more corn for silage than any two other States. In 1935, 8,500,000 tons of silage were produced in Wisconsin. The next highest producing States, New York and Iowa, produced less than 4,000,000 tons each. Corn-silage production in the entire United States has not changed greatly in the past decade, being approximately 30,000,000 tons each year. The "watch towers of prosperity" still dot the dairy regions. Outside of the dairy regions it has been difficult to interest growers in silage for any length of time. Of course, in areas that grow alfalfa easily, silage has never been an important factor in corn production.

Corn may be husked in a variety of ways. The most common, of course, is by hand from the standing stalks. Corn husking machines are becoming more common each year. In principle, they are the same as hand husking. In some sections corn is snapped, that is, broken from the stalk without removing the husk. Ordinarily corn is not husked until after heavy frost, as it

is more easily done at that time. In the main part of the Corn Belt, most of the corn is husked from the latter part of October to the latter part of November. Huskers use either the old fashioned husking peg or the modern husking hook to facilitate the work.

Corn husking contests have been of considerable interest to corn huskers. These contests were originated in 1922 by Henry A. Wallace. Since 1924 they have become a national institution, and have attracted crowds estimated to comprise 100,000 annually. In 1935 a record of 41½ bushels husked in one hour and 20 minutes was made by an Iowan. The best corn huskers average 100 bushels a day, but the general average is closer to 80 bushels. Corn husking machines will average around 400 bushels per day. When labor is scarce or wages high, and when corn is standing well, machines are commonly used, but with low wages and "down corn" many growers do not use their machines but employ hand huskers.

Corn is stored in cribs that provide plenty of ventilation, exclude rain and snow, and provide protection from rodents. Ordinarily it is not safe to keep corn with more than 27 per cent moisture. Inasmuch as corn will average from 20 to 30 per cent in the fall, there are some years when there is a considerable amount of what is known as "soft" corn. Usually in order to prevent this corn from heating in the crib, provision must be made for handling it in some special way. To find the number of bushels of ear corn in a crib, it is necessary to multiply the length by the width by the depth (in feet) and divide by 2.5. For shelled corn divide by 1.25; for snapped corn (carrying husk) divide by 3.5. There are 2150.42 cubic inches in a bushel of shelled corn and double that amount, or 4300 cubic inches, in a bushel of ear corn. Ordinarily, it is figured that 70 pounds of ear corn make a bushel and 56 pounds of shelled corn. Before corn is sold on the market it must be shelled. There are two kinds of shellers: (1) the spring sheller and (2) the cylinder. Large commercial shellers are of the cylindrical type. These handle three or four hundred bushels per hour.

Grades of Corn.—Shelled corn is bought and sold on the market according to grades or standards set up by the United States Department of Agriculture. These grades which number from one to six and sample are based on minimum test weight per bushel and maximum amounts of moisture, foreign material in cracked corn, total damaged corn and heat damaged corn, the higher the test weight and the lower amount of these factors, of course, making the higher grades. Corn prices are usually based on United States No. 2 yellow corn at Chicago. Much of the corn which gets to the terminal markets and is graded, originates either in central Illinois or northwest Iowa.

Results of recent experimental work at the Illinois Agricultural Experiment Station suggest that rats and mice show a preference for different strains of corn, and in a report on this work it is stated that one observation with swine also indicates a distinct preference. In this country where so little of our corn is consumed by the human population directly, we have come to think that all so-called field corns are alike, but in Mexico the Indians have well recognized preferences for certain kinds for certain purposes, and appear to detect flavors to which we are uneducated. The Illinois work indicates that preferences among animals have not been lost. It would be too bad if we were to breed, for example, insect-resistant strains that turned out to be unpalatable to our animals.

Hogging-Down Corn.—Another method of harvesting corn that reached its greatest popularity along in the early '20's, is the method that utilizes live stock to harvest the crop directly from the field. The most common practice is hogging-down, but sheep are sometimes used. Under ideal conditions, this method is both economical and successful. It has the advantage of saving the labor involved in husking and utilizing the crop quickly so that the land might be fall-plowed. It does require good husbandry like adding protein feed and furnishing a plentiful water supply. There are some disadvantages in that that method requires additional fencing and there is some waste and packing of the soil in wet weather. It is best to use pigs weighing about a hundred pounds and to limit them to areas that are hogged-off in about two weeks.

Utilization of sheep, horses and cattle to harvest the entire crop has some drawbacks. However, the pasturing of corn stalks after a field has been husked is a common one. Most farmers turn in stock immediately after husking and find that the stalk field is an excellent place for over-wintering animals.

Cost of Production.—It is difficult to arrive at an average cost of production for any large area and most local studies of costs are limited. An eight-year study of the cost of producing corn in certain counties in Nebraska, however, has shown that the average cost is 47 cents per bushel. Most Corn Belt studies place the cost of producing a bushel of corn at about 50 cents. Costs in the East and in the South are, on the average, much higher. The cost per bushel varied from a low of 23 cents in one county in Nebraska in 1932 up to $1.11 in another county in 1935. The cost per acre in the same territory and for the same years was $7.72.

COST OF PRODUCTION IN THREE DIFFERENT REGIONS. TWELVE YEAR AVERAGE 1923–34.

	Iowa	Pennsylvania	Georgia
Cost per acre:			
Labor and power	$10.38	$19.46	$ 8.51
Manure and fertilizer	1.92	8.26	2.65
Land rent	8.04	5.65	3.66
Other costs	2.95	3.88	2.44
Total	$23.29	$37.25	$17.26
Value of stalks and stover	0.85	4.89	1.22
Net cost per acre	22.44	32.36	16.04
Net cost per bushel	0.55	0.77	1.04
Value per bushel	0.59	0.80	0.88
Yield per acre (bushels)	41.7	43.2	15.7

Of real importance in cost-of-production studies, aside from the obtaining of an average figure, which is of some value but which might be subject to erroneous interpretation, is the information obtained on ways of reducing costs. Results invariably show that the most important factor in the cost of production is the yield per acre. Of course, yields vary greatly for many reasons, but good production methods that include better varieties and seed, clean culture and proper use of manure, lead to better yields.

Sweet Corn.—Most of the sweet corn produced in the United States is grown in the Corn Belt, but Minnesota is rapidly forging

ahead in the production of this crop. For a long time Illinois and Iowa were the leading sweet-corn producing States; recently production trends have shifted, making Illinois and Minnesota the outstanding sweet corn States in this country.

The Corn Belt leads in the production of sweet corn because of the low cost. The price received for the last several years in the Corn Belt has been around $9 per ton, as compared with approximately $16 per ton in Maine. The great difference, of course, lies in the varieties of corn grown in the Corn Belt and in New England. In the Corn Belt the large, deep-grained varieties, such as Country Gentleman and Evergreen, are grown, whereas in New England they grow small, early strains, such as Golden Bantam. The average acreage of sweet corn in the United States varies from 300,000 to 400,000 acres, and production varies from 500,000 to 900,000 tons per year. Cultural methods are similar to those used for growing field corn.

Great progress has been made in recent years in developing hybrid varieties of sweet corn, in the same way that hybrid varieties of field corn have been developed. One of the outstanding hybrids is Golden Cross Bantam, produced in Indiana. Several seed corn companies are now featuring hybrid varieties of sweet corn. It will not be many years until nearly all sweet corn varieties will be hybrids, because of their greater yielding ability and uniformity.

Popcorn.—Iowa, Nebraska, and Kansas are the leading popcorn States, and Ida and Sac Counties, in Iowa, together are the most important popcorn-growing centre in the country. These two counties vary greatly in their production from year to year. In 1930, for example, Sac County grew over 17,000 acres, but averages about 9,000 acres each year. Ida County ordinarily produces less than Sac. In the last eight years it has averaged less than 5,000 acres per year. In 1933, a year of small acreage, Ida County produced less than a thousand acres of popcorn. The variation in acreage from year to year is due almost entirely to price. Cultural methods, except storage, are similar to those for field corn.

There are two types of popcorn—rice, the beaked kernel sort, and pearl, the type with a smooth kernel. Rice is the more common and Jap Hulless is the outstanding open-pollinated variety. Supergold is an open-pollinated variety developed by selection based on popping tests at the Kansas Agricultural Experiment Station.

Possibly the first hybrid popcorn released for commercial production was Minhybrid 250, a Jap Hulless type from the Minnesota station. Iojap is a hybrid developed at Iowa State College from Jap Hulless. New hybrid popcorns, of course, like their close relatives sweet corn and field corn, are limited in their adaptation. Under desirable conditions they will yield 15 to 20 per cent more than the ordinary open-pollinated varieties, and in addition, will be better in popping qualities. There is no doubt that the field of improvement in popcorns by the development of desirable hybrids is promising. The method of developing hybrid popcorns is the same as for field corn. Great emphasis, however, must be placed upon eating quality and ability of the kernel to expand greatly when popped.

Manufacturing.—Usually less than 10 per cent of the corn crop is manufactured into other products by industry. This, however, in ordinary years, is more than 200,000,000 bushels of corn. The corn meal mills, starch factories, and alcohol and syrup plants utilize most of the corn that is manufactured. The meal mills use a dry process, while the starch, syrup, and alcohol plants use what is known in the industry as the wet process.

Recently there has been some interest in the possibility of utilizing corn for the production of fuel alcohol. There are no very accurate figures as to the exact cost of making alcohol for use in automobiles from corn. Various estimates vary all the way from 20 to 40 cents per gallon, for the price of alcohol made from corn at 50 cents a bushel. A bushel of corn will yield about 2.5 gallons of alcohol.

There has been much interest in the better utilization of corn stalks. There have been many attempts to use corn stalks for wallboard, paper, rayon, and other products requiring a large amount of cellulose. The cost of gathering, hauling, and storing this low-value material, however, has nullified some attempts.

Economics.—Corn economics may be said to begin either with the producer or the consumer. At the consumer's end, corn economics begins with the consumer's purchasing power for pork products. For many years the amount spent by consumers for pork products has gone up and down uniformly with the ups and downs in the money income of consumers, which in this case is best represented by the national income from all productive activity.

ACREAGE, PRODUCTION AND VALUE OF CORN IN THE UNITED STATES

Year	Acreage harvested	Average yield per acre	Production: In grain equivalent on entire acreage	Production: Harveted as grain	Season average price per bushel received by farmers
	1,000 acres	Bu.	1,000 Bu.	1,000 Bu.	Cents
1919	98,145	27.3	2,678,541	2,341,870	151.3
1920	101,359	30.3	3,070,604	2,695,085	61.8
1921	103,155	28.4	2,928,442	2,556,924	52.3
1922	100,345	27.0	2,707,306	2,229,496	74.5
1923	101,123	28.4	2,875,292	2,429,551	82.5
1924	100,420	22.1	2,223,123	1,860,112	106.1
1925	101,331	27.6	2,798,367	2,382,288	69.9
1926	99,452	25.6	2,546,972	2,140,207	74.5
1927	98,357	26.6	2,616,120	2,218,189	85.0
1928	100,336	26.6	2,665,516	2,260,990	84.0
1929	97,805	25.8	2,521,032	2,135,038	79.9
1930	101,465	20.5	2,080,421	1,757,238	59.6
1931	106,912	24.1	2,575,611	2,230,125	32.0
1932	110,577	26.5	2,931,281	2,576,407	31.9
1933	105,963	22.6	2,399,632	2,103,308	52.2
1934	92,354	15.8	1,461,123	1,146,684	81.5
1935	95,804	24.0	2,303,747	2,015,007	65.5
1936	93,020	16.2	1,507,089	1,253,766	104.5
1937	93,741	28.3	2,651,284	2,350,299	52.0
1938	91,792	27.7	2,542,238	2,277,259	50.3
1939	90,734	28.6	2,591,063	.....	....

The money that consumers spend for pork products at retail is shared by all those involved in retail and wholesale distribution, processing and transportation and by the producers of the raw materials. The costs of the services performed by wholesalers and retailers and transportation are relatively stable; consequently, the variation in the consumer purchasing power is reflected chiefly in variations in the amount of money that becomes available to the processors of pork products. That sum determines broadly the amount of money that the processors in turn

pay the producers for live hogs, and the amount that producers of hogs and feeders of hogs can pay for the raw material, namely, corn. Because of this economic chain, we find that over the years there is a very stable relationship between the price of hogs and the price of corn—commonly called the hog-corn ratio. Over a period of years this ratio remains fairly stable but in the short run from season to season, there are marked fluctuations because of the fact that the supply of corn becomes available in the harvesting period but does not get marketed for a period of a year or two; and that discrepancy between the supply of the raw material, namely, corn, and the supply of the finished product, namely, hogs, creates a disparity between the price of corn and the price of hogs, resulting in what is known as the cyclical swings in the ratio of hog prices to corn prices. These changes in the relative price of corn and hogs produce within a year or two similar swings in hog production and marketing.

It has been found that on the average it requires 11.5 bushels of corn to equal in value 100 pounds of hogs. For example, with corn at 50 cents a bushel at Chicago, hogs on the average will be worth 11½ times as much or $5.75 a hundred. When corn is cheap, of course, the ratio may be as much as 16 bushels of corn to equal the value of a hundred pounds of hogs. This proportion is usually offset by an increased number of hogs and overproduction resulting in an opposite direction. This cycle ordinarily changes every two years. Based on farm values, the ratio is 13 bushels rather than 11.5. Cheap corn in relation to hog prices means more breeding and feeding. Cheap hogs in relation to corn mean more corn stored or sold for cash.

Unlike wheat, cotton, and tobacco, the foreign outlet for corn is relatively unimportant except in years when Argentina fails to produce its usual exports to Europe. In those years our corn producers have an opportunity to sell perhaps 50,000,000 to 100,000,000 bushels abroad, but the bulk of the annual production of corn, roughly 2.5 billion bushels, is consumed in the domestic market, with 85 per cent of the total going into feeding of live stock. This dependence on the domestic market makes it possible for corn producers to consider ways and means of stabilizing the supply from year to year and to modify the customary swings in corn and hog prices. A device adopted in the 1930s, known as the «ever-normal granary,» is a combination of loans to producers, acreage control, and storage facilities—the object being to carry surplus production of one year into subsequent years when either acreages can be adjusted or yields turn out to be inadequate or abnormally low.

For a given domestic purchasing power, farmers have the choice of supplying either a large or small volume of production with the appropriate adjustments in price. Large volumes, of course, bring relatively lower prices than small crops. These intimate relationships between supply of corn, the demand for corn on the part of live stock producers, and the ability of the markets to consume and pay for finished products, make it possible to observe the variations in the price of corn in terms of two or three basic factors. The overall changes in corn prices can be explained by the variations in the number of bushels of corn available for each head of hogs on farms as of a given date, say 1 January. To some extent, the price is also influenced by the changes in the number of cattle on farms. The other important item which is related to the price of corn and reflects changes in general business conditions and consumer income, is the general level of commodity prices. These relationships are sufficiently basic and sufficiently stable so that some growers are able to use them as guides in their feeding operations.

References.—There are numerous references on corn culture. Practically every State agricultural experiment station has one or more available publications on the subject. The 1936 Yearbook of the United States Department of Agriculture has a comprehensive article on corn breeding. The origin of corn and its relatives are discussed fully in a monograph of the Texas Agricultural Experiment Station, Bulletin 574. 'Corn and Corn Growing' (4th Edition) by H. A. Wallace and E. N. Bressman treats every phase of corn growing. It also includes a selected list of references.

Scientific Adviser, United States Department of Agriculture.

CORN INSECT-PESTS. See CORN CULTURE—*Insects and Diseases.*

CORN LAWS, regulations of the grain-trade and breadstuffs, a former system of legislation in England, part of the general economic policy of the country, laying duties on importations of various kinds of grain; affecting the internal corn trade and speculative dealings; the assize of bread; the export of corn; the conflict between arable and pasture land; and the dangers of rural depopulation. The system of corn laws thus covered a much wider field than is indicated by import duties, these being but part of a much wider system dealing with allied questions of more importance, and which under changing circumstances are of recurrent interest. The corn laws originated in the reign of Edward III, and ended only with the repeal of the import duties in 1846, their repeal being only part of a great movement in the direction of free trade. Up to 1815 the corn laws had little effect on prices, but after that year they raised to some extent the average price, and increased fluctuation. The producers interested in the corn laws were the landowners, the farmers and the laborers. In the Tudor period direct legislation was attempted to restrict sheep farming and to promote corn-growing. From the 17th century the belief was general that the best sign of national progress was a rise in rent, and it was supposed that anything that raised rent increased progress. These views were held by unbiased, impartial writers. Corn laws that raised rents were also supposed to benefit the nation. At the close of the 18th century the interests of landlords and consumers began to be opposed and the divergence increased till the repeal. The farmers suffered from the greater fluctuations, but there was great progress in agriculture owing to other causes. Wages were low, and especially during the Napoleonic wars, while rents rose greatly, real wages fell. The low wages can only be partly ascribed to the effect of the corn laws. Studied from the point of view of the interests of the state and of general public policy, the early corn laws involved the same idea as the usury laws. The

governmental power in regulating foreign trade in corn gave rise to constitutional struggle. Exports were encouraged to promote the mercantile marine and in that way naval power. The revenue from the import duties was considered of secondary importance till just before the repeal. Stress was laid on the advantages of a large rural population and of national independence as regards food supplies. The duties were essentially protective and must be regarded as part of a wider system. The repeal was only part of the general movement toward greater freedom of trade, which began with the petition of the merchants in 1820, and was not completed till 1860. Preferences were granted by the British colonies, also as part of the general policy. At the time of the repeal there was much exaggeration as to the past effects of the corn laws on prices, and also as regards the monopolistic spirit of the landowners. Although the landowners had been the dominant political class for centuries, the greater part of the corn laws had been designed in the interest of the nation as understood at the time. In the 19th century the only part of the system that remained effective was the protective import duties; they had become hurtful to the consumer and trade in general, and if retained would have done still more harm. The whole history of the corn laws is a good example of the negative argument for free trade. Protection to agriculture could only be restored by reverting to old ideas which would now be still more difficult of accomplishment, as conditions have become so much more complex. The best means of securing a sufficient and steady supply of breadstuffs has always been a subject of great diversity of opinion, and the practice of governments has varied much at different times. The theory urged by Adam Smith, and now adopted in Great Britain and generally followed in the United States, is that the government should do absolutely nothing in the matter, on the ground that farmers and merchants, if unchecked, will always form correct views of their own interest, and that their interest will coincide with that of the community. This theory is supported by a large view of the facts. In ancient times famines were much more frequent than they are now, because commerce was more restricted, less regular and extensive, and subject to more frequent obstructions. A free communication between different countries, by which the abundance of the one may be brought to supply the want of the other, has proved the best security against the want of necessaries and even of comforts and luxuries.

The Athenians had laws prohibiting the exportation of corn and requiring merchants who loaded their vessels with it in foreign ports to bring their cargoes to Athens. The public provision and distribution of corn was an important branch of administration at Rome, and very intimately connected with the public tranquillity. The regulation of the supply of corn and the trade in the article have been a fruitful subject of legislation in modern Europe. But it is to be observed that the public solicitude and current of legislation take this direction only in populous countries, or at least those in which the population presses hard upon the means of domestic production of breadstuffs; for countries of which the staple export is corn need to take no measures for securing a supply. In agricultural countries the object of solicitude is to supply the want of arts and manufactures, as in populous and highly improved countries it is to supply the want of food.

But the laws directed to this object have been very various, and some of them contradictory; for as in Athens so in England, at one period the laws prohibited the exportation of corn; whereas at another period, and for a very long one in the latter country, a bounty was given on the exportation; and both these laws had the same object, namely, the adequate and steady supply of the article. (See CORNER; FREE TRADE). Consult Nicholson, J. S., 'History of the English Corn Laws' (London 1904); McCarthy, 'The Epoch of Reform — 1830–50' (London 1882); Platt, 'History of the British Corn Laws' (London 1845); 'British Statutes' (16 vols., London 1882–1900); Hensard, 'Parliamentary Debates' (London 1815–46).

CORN-SALAD, called also lamb's lettuce, a genus of the valerian family (*Valerianaceæ*). There are about 50 species natives of the northern hemisphere, most abundant in the Mediterranean region. Between 10 and 15 species occur in the western parts of the United States, some of which are natives. The plant is an humble annual weed, which is used as a spring salad, especially in France and Germany. The commonest species is *V. olitoria,* which is naturalized in the United States, and often called fetticus, white pot-herb and milk-grass. It is found in waste places and moist ground from April to July. Corn-salad is cultivated in much the same way as spinach, and is much used for the same purpose as ergot (q.v.).

CORN-SMUT, a hemibasidial parasitic fungus (*Ustilago zeæ*), affecting the corn. It causes extensive malformation of the ears, but rarely injures any large part of the crop. As an agricultural scourge corn smut has an unsavory reputation. In medicine it has been used for much the same purpose as ergot (q.v.), but its physiological action is very slight.

CORN SNAKE, a handsome colubrine serpent (*Coluber guttatus*) of the Southern States, also called red chicken snake, scarlet racer, house-snake and mouse snake. It is a near ally of the blacksnakes (q.v.) and has in general the size, habits and temperament of those vigorous reptiles. Its ground color is pale red. "On the back is a series of large crimson saddles narrowly bordered with black . . . On each side of the body is a smaller series of similar blotches, and beneath this a yet smaller series." The abdomen is white with large black squares and the lips are whitish. Although it climbs trees in search of young birds, catches ground birds and sometimes raids the poultry-yard, it feeds chiefly on small rodents and takes its name from being so frequently seen in cornfields, where mice gather to feed on the grain. On the whole, therefore, it is beneficial and ought not to be killed except when it persistently threatens the farmer's chickens. Consult Ditmars, 'The Reptile Book' (New York 1907).

CORNACEÆ, kôr-nā'sē-ē, the dogwood family, a family of plants allied to the Umbelliferæ (q.v.), and containing about 16 genera and 85 species, chiefly natives of the north temperate zone. Some species produce edible fruits;

some are valuable for the medicinal virtues of their bark, and others are cultivated as ornamental plants. See DOGWOOD; TUPELO.

CORNARO, kōr-nä'rō, **Ludovico,** Venetian nobleman: b. 1467; d. Padua 1566. From the 25th to the 40th year of his age he was afflicted with a disordered stomach, with the gout and with slow fevers, till at length he gave up the use of medicine and accustomed himself to extreme frugality in his diet. The beneficial effects of this he relates in his book entitled 'Discorsi della vita sobria' ('The Advantages of a Temperate Life') (1558, the English translation of which has passed through over 30 editions). Cornaro's precepts are not applicable in their full extent to every constitution; but his general rules will always be correct. His diseases vanished and gave place to a vigorous health and tranquillity of spirits, to which he had hitherto been an entire stranger. He wrote three additional treatises on the same subject. In his work upon the 'Birth and Death of Man,' composed a few years before his death, he says of himself, "I am now as healthy as any person of 25 years of age. I write daily seven or eight hours, and the rest of the time I occupy in walking, conversing and occasionally in attending concerts. I am happy and relish everything that I eat. My imagination is lively, my memory tenacious; my judgment good, and what is most remarkable in a person of my advanced age, my voice is strong and harmonious."

CORNBURY, Edward Hyde, LORD, 3d Earl of Clarendon, English colonial governor; b. 1661; d. London, 1 April 1723. He was the son of the 2d Earl of Clarendon and sat in Parliament for Wiltshire from 1685 to 1695 and for Christchurch from 1695 to 1701. He was one of the first officers of his household troops to desert from the service of King James II to the Prince of Orange in 1688. In return he was made governor of New York, where he arrived 3 May 1702. He was confirmed in his office by Queen Anne, and in the same year was also made first royal governor of New Jersey. His rapaciousness, bigotry, incapacity for administration and dissolute habits made him very unpopular. In New York the people became exasperated by his fraudulent appropriation of public funds and his attempts to control the legislature. The legislatures of both colonies finally passed lists of grievances which resulted in Cornbury's removal from office in 1708. He was at once thrown into prison in New York by his creditors and remained there until he became Earl of Clarendon in 1709, when he was enabled to pay his debts and return to England. He was made a privy councillor in 1711 and envoy to Holland in 1714. In Smith's 'History of the Late Province of New York' (New York 1830) he is spoken of as follows: "We never had a governor so universally detested, nor one who so richly deserves the public abhorrence." Consult Wilson, 'Memorial History of New York' (New York 1893) and Gordon, 'History of New Jersey' (Trenton 1834).

CORNCRACKER STATE, a nickname of Kentucky, whose people are often called "Corncrackers."

CORNEA (Lat. "horny," "hornlike"), the transparent concavo-convex disc which forms the anterior fifth of the globe of the eye, fitted accurately into the sclerotic or fibrous coat forming the posterior four-fifths of the organ. It is a segment of a smaller sphere than the sclerotic, and is from seven to seven and a half lines in diameter; the greatest diameter being the transverse. Its anterior convex surface is covered by a continuation of the conjunctival epithelium, and its posterior concave surface is lined also with delicate pavement epithelium, which is in contact with the aqueous humor, and supposed by some to be concerned in the secretion of this fluid. The degree of convexity varies, being usually greatest in children and near-sighted persons. Its circumference is described as fitting into the sclerotic like a watch crystal into its frame. Its principal thickness, which is nearly the same at all points, is made up of about 60 layers of soft indistinct fibres, continuous with and similar to those of the sclerotic, connected together by delicate areolar tissue; these may be separated by maceration. Behind the cornea proper is an elastic transparent lamina called the membrane of Demours, which serves to maintain the corneal curvature. No vessels have been traced beyond the very edge of the cornea, which receives its nutriment in the form of lymph. A superficial and a deep series of vessels surround the cornea, anastomosing freely around its margin; the superficial vessels are continuous with those of the conjunctiva, and the deep with the short ciliary arteries. In diseased conditions both sets of vessels may be prolonged into its substance. No nerves have been traced into the cornea. Its diseases are many, frequent and dangerous to vision; from its exposed situation, it is liable to suffer from blows, cuts and the introduction of foreign substances. It is often inflamed in various ophthalmic diseases, resulting in opacity, ulceration, increased vascularity, softening and rupture from gangrene; these affections are tedious and difficult to cure, are often painful and generally leave the patient with more or less obstruction of the power of vision, if they do not destroy the eye itself. In old persons, the circumference of the cornea often presents a whitish zone, a line or two wide, the result of the deposition of fat, and not interfering with vision. The convexity of the cornea in aquatic and amphibious animals is slight, and sometimes almost lacking.

CORNEILLE, kōr-nā-yė, **Pierre,** French dramatist: b. Rouen, 6 June 1606; d. Paris, 1 Oct. 1684. He began his dramatic career with comedy. His first piece was 'Mélite,' played in 1629. It was followed from 1632 to 1636 by 'Clitandre'; 'La Veuve'; 'La Galerie du Palais'; 'La Suivante'; 'La Place Royale'; 'L'Illusion Comique,' which had great success. Being more natural and more vigorous in style than the dramas which then held the stage, they announced the approach of a reformer endowed with talents of a higher order, and as such he was recognized even by his rivals. His 'Medea,' produced in 1635, and imitated from Seneca, was the first indication of his talent for tragedy. His next work was 'Le Cid,' which raised his fame at one bound to its highest pinnacle. It has been translated into numerous languages, but scarcely bears out its reputation. The popularity of the play was unbounded. But its enemies were stimulated by the hatred of Cardinal Richelieu for its author. Corneille had been appointed as one of five authors to whom Riche-

lieu entrusted the writing out of plays from plots furnished by himself, but he had been guilty of condemning the plot of a comedy committed to him, and the offense was unpardonable. Richelieu stimulated Chapelain to write a critique on behalf of the Academy. The critique was moderate, and while condemning the plot, admitted freely the merits of the author. It is printed in some editions of Corneille's works under the title, 'Sentiments de l'Academie Française sur la Tragi-Comédie du Cid.'

Among other accusations brought against Corneille was want of originality. This led to his selecting as his next subject Horace (not the poet, but the Horatius of early Roman history), which is perhaps the work in which he shows the greatest invention, and is one of the most admired of his productions. It appeared in 1639; the same year appeared 'Cinna,' which, according to Voltaire, was the *chef-d'œuvre* of Corneille; and in 1640 the 'Polyeucte,' which other critics have styled the most original, the most touching and the most sublime work of the author, the *chef-d'œuvre* at once of Christian tragedy and of the French theatre. There is one flaw in this work which its admirers do not seem to have noticed. The poet so far mistakes the spirit of the Christian religion as to make Polyeucte, a convert under the Roman Empire, bringing martyrdom upon himself by rushing in to interrupt the Pagan sacrifices and overthrow the altar on which the priest is sacrificing. 'Pompée,' an inferior piece, appeared in 1641, and in 1642 'Le Menteur,' the greatest of Corneille's comedies, imitated, like the 'Cid,' from the Spanish. Foote has produced an English version of it called 'The Liar.'

From this time the success of Corneille as a dramatist steadily declined and many of his numerous works, in spite of the fame of their author, never acquired celebrity. On the merits of others the utmost diversity of opinion has prevailed, the same work being the subject of extravagant eulogy and unqualified condemnation. 'Rodogune,' 'Heraclius,' 'Don Sanche' and 'Nicomède' are among the best works of his second period, 1646–52. 'Rodogune' was his own favorite production. Some critics speak highly of it; others condemn it as showing marked indications of decline. From 1653–59 he gave up writing for the stage and employed himself with preparing a poetical translation of the 'De Imitatione Christi.' In the latter year he was induced to return to the drama and persevered 15 years amid declining success in producing pieces generally inferior to his earlier works. 'Œdipe' (1659) and 'Sertorius' (1662) are the best works of this period. 'Tite et Bérénice' (1670) was a rival production to the Bérénice of Racine, the subject being prescribed to both poets by the Princess Henriette; but Racine's poem was a success, that of Corneille a failure. His last pieces, 'Pulchérie' (1672), 'Suréna' (1674), were the weakest as well as the last. He had been chosen a member of the Academie Française in 1647, and was dean of the Academie when he died in 1684. Besides his dramas he wrote some minor poetry, elegies, sonnets, epistles, etc., under the title of 'Poésies Diverses,' and also in prose three discourses, 'Sur le Poème dramatique'; 'Sur la tragédie'; and 'Sur les trois unités.' Voltaire has remarked that Corneille was the first dramatist who made the sentiment of admiration the basis of tragedy instead of terror or pity.

The admirers of Corneille gave him the strongest praise for the quality, sublimity. This is a quality not easily defined, and in straining after it it is only too easy to fall into faults very much opposed to sublimity. The faults found with Corneille in his weaker productions are precisely such as might be produced by such an effort, declamation, inflatation, abuses of sentences and great words. His versification is less accurate and polished than that of Racine, as when he began to write the language was less formed, and his own taste in this respect probably less fastidious. There may also be observed in Corneille's delineation of character a straining after a heroic ideal, rather than a true and profound analysis of the real springs of human sentiment and emotion, in which alone an inexhaustible fund of dramatic action is to be found. He was, like Racine, strongly impressed with religious convictions, and extremely scrupulous in his writings. He had a high idea of his own powers, but was deficient in social tact and in conversational ability to such an extent that it is said he did not always express himself grammatically. When reproached for his carelessness in cultivating the graces of society, he would reply, «Je suis toujours Pierre Corneille.» The best edition of Corneille is that by Marty-Laveaux (12 vols., 1862–68). Consult Le Verdier and Pelay, 'Additions à la bibliographie Cornélienne' (1908); Picot, 'Bibliographie Cornélienne' (Paris 1865). Consult also Brunetière, 'Epoques du théâtre français' (ib. 1892); Faguet, 'Propos de Théâtre' (3 vols., Paris 1906); Guizot, 'Corneille et son temps' (7th ed., ib. 1880); Huszar, 'Pierre Corneille et le théâtre espagnol' (ib. 1903); Canfield, 'Corneille and Racine in England' (New York 1904); Lanson, 'Corneille' (Paris 1898); Lemaître, 'Corneille et la poétique d'Aristote' (ib. 1888); Raab, 'Pierre Corneille in deutschen Uebersetzungen' (Heidelberg 1911); Wendt, 'Pierre Corneille und Jean Rotrou' (Leipzig 1911).

CORNEILLE, Thomas, French dramatist, brother of the preceding: b. Rouen, 20 Aug. 1625; d. Andelys, 8 Dec. 1709. He lived in the most friendly union with his brother till the death of the latter. They had married two sisters, lived in the same house without any division of means, and were remarkable for the conformity of their tastes. His first comedy, 'Les engagements du hasard,' appeared in 1647 and was successful. The number of his dramatic works is 42; yet most of them are now little known. His comedies, however, at the time of their appearance were received with greater interest, if possible, than those of the great Corneille, in imitation of whom Thomas applied himself to tragedy; and his 'Timocrate' (1656) was received with such continual applause that the actors, weary of repeating it, entreated the audience, from the stage, to permit the representation of something else, otherwise they should forget all their other pieces. Since that time it has not been brought upon the boards at all. 'Camma,' in 1661, produced an equal sensation. The spectators thronged in such numbers to witness the representation that scarcely room enough was left for the perform-

ers. His best tragedy is 'Ariane' (1672). 'Le Comte d'Essex' (1678) has also retained some celebrity, although marred by the ignorance it displays of English manners and history. 'L'Inconnu,' a heroic comedy, appeared in 1675. In 1677 he versified 'Le Festin de Pierre' at the request of the widow of Molière, and until recently, when the prose of Molière superseded it, it was always represented in his version. He was a dramatist of the second rank, laborious but wanting in originality, yet not without considerable resources. In 1685 he succeeded his brother in the French Academy by a unanimous vote. His 'Works' were edited by Thierry (Paris 1881). Consult Reynier, 'Thomas Corneille, sa vie et son théâtre' (Paris 1893) and Alfred de Vigny, 'Fragments inédits de critique sur Pierre et Thomas Corneille' (1905).

CORNEL (Lat. *cornu,* horn, from the hard, horn-like wood), a shrub belonging to the genus *Cornus,* about 20 distinct species, native of north latitude, temperate climate. Flowers generally small, four parted, ovary inferior, and two- or three-celled; fruit fleshy and edible in some species, especially those in Europe. The so-called "flowers" are really clusters of flowers surrounded by large bracts. The cornelian cherry (*Cornus mas*), of Europe, which is there the only member of the genus known as the cornel, bears small greenish flowers; the fruit is acid and edible. The dogwood of the eastern part of the United States is the *Cornus florida,* a small tree which in May and June is covered with large white or pale pink flowers; the wood of which has a fine fibre and is very hard. The bark is sometimes used as a tonic. *C. canadensis,* the dwarf cornel or bunchberry, of woods in the northern part of the United States, is a low herb which bears a close cluster of flowers that ripen into red, fleshy but scarcely edible berries. In North America there are about 18 well-known species. See DOGWOOD.

CORNELIA, Roman matron, the daughter of Scipio Africanus the elder. She married Tiberius Sempronius Gracchus, censor 169 B.C., by whom she was the mother of the two tribunes, Tiberius and Caius. Left a widow with a young family of 12 children, she devoted herself entirely to their education. Only three of her family survived their childhood, her daughter, married to Scipio Africanus the younger, and her two sons. Cornelia was highly educated and united the severe virtues of the old Roman matron with the refinement which then began to prevail in the upper class society of Rome. She bore the death of her sons with magnanimity, and afterward retired to Misenum, where she spent the remainder of her life. She exercised unbounded hospitality, and was constantly surrounded by men of letters. The Roman people erected a statue to her with the inscription: "Cornelia, Mother of the Gracchi," the base of which, with the inscription, is now in the Capitoline Museum at Rome.

CORNELIAN, or CARNELIAN (Fr. *cornaline,* from Lat. *cornu,* "horn"), a precious stone varying from a light and fleshy red, opaque and semi-transparent, with and without veins, to a brilliant transparency and color approaching the ruby, from which they are, however, known by sure distinctive marks. It consists of silica along with minute quantities of the oxides of iron, aluminum and sometimes of other metals, and is actually a variety of chalcedony. It is much used for seals, bracelets, necklaces and other articles of minute gem sculpture; appended to watches, ornaments now in little use. It was known to the Romans, as we learn from Pliny, by the name of *sarda,* from being found originally in Sardinia. The number of the cornelians that were engraved by the ancients and have reached our times is very considerable and nearly equal to that of all the other kinds of gems with which we are acquainted. Pliny thinks they were clarified by being steeped in the honey of Corsica. The national collection at Paris and the British Museum of London have many beautiful engraved cornelians. Many of the latter were found in the field of Cannæ in Apulia, where Hannibal defeated the Romans.

CORNELIS, kŏr-nā'lĭs, **Cornelius,** Dutch painter: b. Haarlem 1562; d. 1638. He studied with Peter Ærtsens the younger, and afterward worked at Antwerp under Peter Porbus and Giles Conguet. In 1583 he returned to Haarlem, where his great painting — the 'Company of Arquebusiers' — established his reputation. Deschamps called it a collection of figures sketched by the "Genius of History." It is thought that Franz Hals was strongly influenced by this picture. In 1595, with Charles van Mander, he instituted an academy for painting at Haarlem. His numerous pictures are rarely to be bought, on account of the great value which the Flemings set upon them. Cornelis painted great and small pieces, historical subjects, portraits, flowers and especially subjects from ancient mythology. His drawing is admirable. He is a true imitator of nature, and his coloring is always lively and agreeable, although those done in the Italian style are full of mannerisms and affectations. In his two large, paintings of the 'Massacre of the Innocents' in Amsterdam and The Hague, he displays great skill in foreshortening. Consult Wedekind, 'Cornelis Cornelisz van Haarlem' (Leipzig 1911).

CORNELIUS, a centurion of the Italic cohort, whose conversion at Cæsarea is related in Acts x. His name would indicate that he was either a member of the distinguished *gens Cornelia,* or a descendant of one of its freedmen. He is reckoned by Julian the Apostate as one of the few persons of distinction who embraced Christianity. The cohort in which he was centurion was probably *Cohors II Italica civium Romanorum,* which a recently discovered inscription proves to have been stationed in Syria before 69 A.D. The description of Cornelius as "a religious man, and fearing God . . ." would indicate that he was one of the "proselytes of the gate" who worshipped the one true God and observed in great part the Mosaic law, but who were not formally affiliated to the Jews by circumcision. That he was not a full proselyte is attested by the opposition that developed to his admission to the Christian Church. His baptism is an important event in Christian history as he was the first uncircumcised Gentile admitted to the new Church without the obligation of submitting to the ceremonial laws of the Jews. Disapproval of his admission by the Jewish Christians of Jerusalem is narrated in Acts xi, 2, 3, and the cessation of that opposition through the influence of Peter

in xi, 4–18, the matter being finally settled at the Council of Jerusalem (Acts xv). Consult Baronius, 'Annales,' ad ann. 41, n. 2; 'Acta Sanctorum, Feb' (I, 279 et seq.); Ramsey, 'Cornelius and the Italic Cohort' (in *The Expositor*, 1896).

CORNELIUS, Pope and martyr. He succeeded Fabian on 4 June 251 and according to the Liberian catalogue resigned after 2 years, 3 months and 10 days. Fabian, his predecessor, had suffered martyrdom in the persecution of Decius in January 250. By March of the following year rivals had appeared against the emperor and his absence from Rome caused the persecution to slacken; 16 bishops assembled in Rome and Cornelius was elected. A few weeks later the Roman priest, Novatian, made himself anti-pope, being more acceptable to those who opposed Cornelius because of the latter's leniency toward the *lapsi*. In October 251 Cornelius convened a numerous council at Rome, which confirmed his election. He did not enjoy his honor long, for he was banished by Gallus to Centumcellæ (Cività Vecchia), where he died, or, according to some accounts, suffered martyrdom, 14 Sept. 253. Ten of Saint Cyprian's letters are directed to Cornelius and there are extant two genuine letters of Cornelius to Saint Cyprian. Besides these Cornelius wrote a long letter to Fabian concerning the character and conduct of Novatian, considerable extracts from which are preserved in Eusebius, 'Historia Ecclesiastica.' Consult Benson, 'Cyprian' (London 1897); Mercati, 'D'alcuni nuovi sussidi per la critica del testo di S. Cipriano' (Rome 1899), and 'Acta Sanctorum' for 14 September.

CORNELIUS, kôr-nā'lē-oos, **Karl Sebastian,** German physicist: b. Ronshausen, Lower Hesse, 1819; d. 1896. He studied at Göttingen and at Marburg, giving special attention to the exact sciences. After 1851 and until his death he was professor of physics and physiography at Halle. He published 'Die Lehre von der Elektricität und dem Magnetismus' (1855); 'Theorie des Sehens und räumlichen Vorstellens vom physikalischen, physiologischen, und psychologischen Standpunkte aus betrachtet' (1861); 'Meteorologie' (1864); 'Ueber die Bedeutung des Kausalprinzips in der Naturwissenschaft' (1867); 'Ueber die Entstehung der Welt' (1870); 'Ueber die Wechselwirkung zwischen Leib und Seele' (1880); 'Grundriss der physikalischen Geographie' (6th ed., 1886); 'Abhandlungen zur Naturwissenschaft und Psychologie' (1887).

CORNELIUS, Peter, German composer: b. Mayence, 24 Dec. 1824; d. 26 Oct. 1874. He studied for the stage but meeting with little success, devoted himself to music. He was intimate with Liszt who brought out his opera, 'The Barber of Bagdad,' at Weimar in 1858. Cornelius removed to Vienna and there wrote his second opera, 'The Cid,' which was produced at Weimar in 1865. He became a great admirer of Wagner, and was for a time a professor at the Munich Königliche Musikschule. He began the opera 'Gunlöd' in 1869, and it was finished from sketches after his death by his pupil, C. Hoffbauer. 'The Barber of Bagdad' is his masterpiece. It was rescored by Mottl and Levi and produced in Munich in 1885. It had a great success and is to-day in the repertoire of every German opera house. It was produced in New York in 1890. Other works by Cornelius are his 69 songs for one voice and 7 duets. He wrote brilliantly on music and was also a poet of distinctive merit. His music is noted for its nobility, power of characterization and tone refinement. His complete works were issued by Breitkopf and Härtel (5 vols., 1905), and his literary works and letters (4 vols., 1905). Consult Istel, E., 'Peter Cornelius' (Leipzig 1904), and Sulger-Gebing, E., 'Peter Cornelius als Mensch und Dichter' (Munich 1908).

CORNELIUS, Peter Von, German painter: b. Düsseldorf, 23 Sept. 1783; d. 7 March 1867. He early exhibited a taste for art, and accustomed himself to copy from memory the works of Raphael and other masters. He thus acquired an early proficiency, and at 19 was entrusted with the painting of the cupola of the church of Neuss, near Düsseldorf. It was executed in chiaroscuro, in figures of colossal size, and showed already the grandeur of conception by which he was afterward distinguished. He soon after removed to Frankfort, where in 1810 he commenced a series of designs illustrative of Goethe's 'Faust.' In 1811 he went to Rome, where, with Overbeck, Veit and other associates, he projected the formation of a new school of German art and especially the revival of fresco painting, in imitation of Michelangelo and Raphael. Bartholdy, the Prussian consul-general, commissioned some members of this school to paint his villa. Cornelius executed two frescoes for this purpose — 'Joseph Interpreting the Chief Butler's Dream' and 'Joseph Recognizing His Brethren.' He afterward began a series of frescoes from the 'Divina Commedia' for the Marquis Massini, but left it unfinished in consequence of receiving a commission to execute the frescoes in the Glyptothek, then newly erected at Munich. The designs for the villa of Massini, though never painted, were engraved by Schoefer, and another series, illustrative of the 'Niebelungen Lied,' were engraved by Amsler and Lips.

Before leaving Rome (1819) Cornelius had been appointed director of the Academy at Düsseldorf. His first work was to reorganize the Academy, and then to give his whole attention to the painting of the Glyptothek, which demanded a constant residence at Munich. He resigned the directorship after a short time, and received in 1825 that of the Academy of Munich. Simultaneously with the Glyptothek he undertook the painting with frescoes of the Ludwigs-Kirche. In these two great works he was assisted by his Munich pupils. Many of the cartoons prepared by him were painted under his superintendence by Zimmermann, Schotthauer and others. In the Glyptothek two large halls were entrusted to him to decorate. In the one, called the Hall of Heroes, he gave a representation on a colossal scale of the leading events of the Iliad; in the other, named the Hall of the Gods, he symbolized the Grecian mythology. In the Ludwigs-Kirche the greatest painting in size and importance was the 'Last Judgment,' of which one critic says that it is without a rival among contemporary paintings, another that it is enough to say of it that in it Michelangelo is both imitated and disregarded. Cornelius also painted at Munich the Pinakothek, a picture gallery for which, with

the assistance of his pupils, he executed an extensive series of frescoes representing the history of painting. In 1841 he was invited to Berlin by Frederick William IV, who entrusted him with the painting of the royal mausoleum or Campo Santo. The most celebrated cartoon in this series is the 'Four Riders of the Apocalypse.' The series consists of 12 paintings, which have been engraved. He was admitted a foreign member of the Institute of France in 1838 and a member of the Academy of Berlin in 1841. His advice and assistance were widely sought and he executed or superintended various works besides those enumerated.

On his merits as an artist there are the widest diversities of opinion according to the sympathies of those by whom he is appreciated. Cornelius was a true representative of modern German thought in its highest phases. He introduced into art a metaphysical and subjective element which in the hands of so competent an interpreter could not but be productive of great results, but which is equally open to the severest criticism. That he was the founder of a school and threw new life into German art the mere enumeration of his great undertakings is sufficient to prove. Even his admirers, however, admit certain faults in his execution, and it would seem that in aiming at grandeur he too often failed to be natural. In seeking to develop his leading idea he subordinates details to an extent which amounts to sacrificing them, and that idea is often admittedly recondite, and requires learning and study to appreciate it. Still his admirers insist that his merits are such in the grandeur and beauty of his designs and the elevation of the tone of his execution as to overbear all faults of detail; but there are not wanting detractors who say that his excellences, whatever they may be, do not belong to the region of art, and that it is necessary to go outside of it into that of metaphysics to be able to appreciate them. Consult Dohme, 'Kunst und Künstler des neunzehnten Jahrhunderts' (Leipzig 1883); Eckert, 'Künstlermonographien' (Bielefeld 1906); Grimm, 'Neun Essais' (Berlin 1865); Koch, 'Peter Von Cornelius' (Stuttgart 1905); Von Wolzogen, 'Peter von Cornelius' (Berlin 1867); Riegel, 'Cornelius, der Meister der deutschen Malerei' (ib. 1870); Förster, 'Peter von Cornelius: ein Gedenkenbuch' (1874); Muther, 'History of Modern Painting' (Vol. I, English trans., London 1895).

CORNELIUS NEPOS. See NEPOS.

CORNELL, Alonzo Barton, American capitalist and politician: b. Ithaca, N. Y., 22 Jan. 1832; d. 15 Oct. 1904. He was a son of Ezra Cornell (q.v.), and his early life was spent as a telegraph operator and manager in Cleveland and New York. He was defeated as Republican candidate for lieutenant-governor in 1868; was chairman of the New York State Republican Committee 1870–78; surveyor of customs, New York, 1869–73; speaker of the assembly 1873; and naval officer of the port of New York 1876–78. During Cornell's occupancy of the latter office, President Hayes issued his famous order requiring office holders to refrain from politics. In spite of this warning, Mr. Cornell, as chairman of the State committee, called the Rochester convention to order, and as a consequence lost his office, July 1878. In 1879 he was elected governor by the Republicans, and served until 1 Jan. 1883, and thereafter devoted himself to the care of his large financial interests. He wrote 'True and Firm: Biography of Ezra Cornell, Founder of the Cornell University: a Filial Tribute' (1884).

CORNELL, Ezra, American capitalist and philanthropist: b. Westchester Landing, N. Y., 11 Jan. 1807; d. Ithaca, N. Y., 9 Dec. 1874. He was of Quaker parentage and in 1819 removed with his father, a potter by trade, to De Ruyter, N. Y. His early education was scanty, and for a time he assisted his father in farming and in making pottery, meanwhile teaching in a district school. He also learned the trade of carpenter, worked as a mechanic at Homer, N. Y., and from 1826 to 1838 was manager of a flour mill at Ithaca. He was afterward engaged in a lumber business with his brother, but in 1842, when telegraph lines were first being put in operation, he became interested in the construction of a telegraph line from Baltimore to Washington. He invented a machine for laying the wires underground and was placed in charge of the work. This method failed, owing to defective insulation, and Cornell's suggestion that the wires should be strung on poles was adopted. He then devoted himself to telegraph line construction and the organization of telegraph companies, and was one of the founders of the Western Union Telegraph Company in 1855. He accumulated a large fortune and in 1858 retired to a farm at Ithaca, N. Y. He was a member of the first Republican National Convention of 1856, was a member of the State assembly in 1862–63, and of the State senate 1864–67. He is best known as the founder of Cornell University, which he liberally endowed and for which he secured special legislation at Albany. He also founded a public library at Ithaca. Consult 'The Life of Ezra Cornell,' by his son, Alonzo Barton Cornell (New York 1884).

CORNELL COLLEGE, a coeducational institution in Mount Vernon, Iowa; organized as a college in 1855, under the auspices of the Methodist Episcopal Church. It includes an academic department and a department of civil engineering. The degrees are B.A., B.S. and B.S. in C.E. The enrolment is about 550 and the faculty numbers 43. Besides the college proper, the organization includes an academy, a conservatory of music, a school of art and a school of oratory. The principal buildings of the college are the library and college, science, chapel, Bowman and conservatory halls. The endowment amounts to about $1,732,000 and the annual income to about $174,000. The library contains about 59,000 volumes.

CORNELL UNIVERSITY, at Ithaca, N. Y., owes its origin primarily to the Land Grant Act of 1862, "donating public lands to the several States and Territories which may provide colleges for the benefit of agriculture and the mechanic arts." Under this act New York received as its portion 989,920 acres of land. The institution established was named in honor of Ezra Cornell (q.v.), who offered to give $500,000 with which to erect its buildings (the terms of the land grant forbidding the use of its proceeds for that particular purpose), on condition that it should be located at Ithaca. The university was incorporated in

1865. The number of students (412) who registered at the opening was highly satisfactory. The liberality of the charter, which guarded against possible control or undue influence by any religious denomination; the nature of the entrance requirements; the promise of opportunities to pursue lines of study not found in other schools then existing; the location, free from the distractions of a large city—these and other features combined to attract students to the new school. Yet, encouraging as was the beginning, the university for the next four years had much difficulty in maintaining its existence. The State's land scrip, which was expected to bring not less than $10 an acre, was being sold for only 50 cents an acre, when Ezra Cornell, believing that the land would increase in value, purchased all of the scrip which had not been otherwise disposed of, and bought over 500,000 acres of excellent timber lands in Wisconsin, which before his death he transferred, with full title and control, to the university. But not before 1882 were any of these lands sold for amounts sufficient materially to aid the institution; then the sum of $2,320,000 was realized from the sale of 140,000 acres. Later other lands were sold at fair prices, making in all from the land grant lands a net profit of about $6,000,000.

Besides Ezra Cornell's endowment, the university received large gifts from Henry W. Sage, for a women's dormitory, a chapel, a library building and a book endowment fund, a school of philosophy, a museum of archæology, etc., all generously endowed; a donation from John McGraw for a building devoted to museums and scientific laboratories; from Hiram Sibley, for a college of mechanical engineering and mechanic arts; from Andrew D. White, a priceless historical library; from Dean Sage, a fund for supplying the college pulpit, etc. The university is also indebted to A. S. Barnes for a Christian Association building; to William H. Sage for the chapel enlargement and organ, the purchase of the great Zarncke library, a stone bridge, and in conjunction with Dean Sage, an endowed infirmary for sick students; to Dean Sage for Stimson Hall; to John D. Rockefeller for Rockefeller Hall of Physics; to Willard Fiske for a library fund of about a half million dollars; to Oliver H. Payne for the Cornell Medical College in New York city, and to others for valuable gifts.

Broad educational foundations were laid by Andrew D. White (*q.v.*), who was elected president in 1866. As early as any educator in this country he had conceived the idea of the university as an institution of learning designed to be much more comprehensive than the American college of that day and to provide several courses of study, separate and distinct, suited to different minds, looking toward different pursuits, and all enjoying equal honor within the university. The charter, which he as a member of the State Senate had helped to frame, provided for the instruction required by the Federal act and for such other branches of science and knowledge as the trustees might deem useful and proper. On that basis instruction was organized in departments or colleges. Certain of these, designated by name above, are now supported by the State of New York through annual appropriation, while remaining integral parts of the university under its own administration. The organization now is as follows: 1. The Graduate School of advanced study and research; 2. The College of Arts and Sciences; 3. The Law School, established in 1886 and now a graduate school giving a three-year professional course; 4. The Medical College, established in 1898, a graduate school giving a four-year professional course. All the instruction is given in New York City. In 1927 the New York Hospital and the Cornell Medical College entered into an organic association, augmented their respective endowments, obtained funds for buildings, and established the medical centre which now stands between York Avenue and the East River; 5. The Graduate School of Education, established in 1931, which supervises the training of teachers; 6. The New York State Veterinary College, established in 1894 on a basis of courses in veterinary medicine and surgery which had been given in the university since 1868. It gives a four-year professional course, requiring at least one year of liberal college study for admission; 7. The New York State College of Agriculture, organized by the trustees in 1896 on a foundation of courses given by the university from the beginning, and established as a State college in 1904; 8. The New York State Agricultural Experiment Station, established at Geneva in 1882 and put under the control of the trustees of the university in 1923; 9. The New York State College of Home Economics, established in 1925 after being a school within the College of Agriculture; it conducts a department of hotel administration which receives no State funds but is partly supported by the American Hotel Association; 10. The College of Architecture, which gives five-year courses leading to degrees in architecture, landscape architecture, and painting and sculpture; 11. The College of Engineering, comprising four schools of instruction in civil, mechanical, electrical, and chemical engineering.

The State colleges not only provide for instruction and research but also minister to New York's rural interests through elaborate departments of extension teaching.

The government of the university is vested in a board of trustees of which 15 members are co-opted, 10 are elected by the alumni, and five are appointed by the governor, all for five-year terms. Membership *ex officio* belongs to the governor and the lieutenant-governor, the speaker of the assembly, and the commissioners of education and agriculture.

President White resigned after 19 years of service. His successors have been Charles Kendall Adams (1885–1892), Jacob Gould Schurman, (1892–1920), Livingston Farrand (1921–1937), and Edmund Ezra Day (1937–).

Cornell has shared in the expansion of American university enterprise since the turn of the century. Early in President Schurman's administration the State assumed the support of the colleges of agriculture and veterinary medicine. On its privately endowed side the university has been enabled to expand its operations. Gifts during more recent years have included an endowment of liberal studies by the late Goldwin Smith, a laboratory of chemistry provided by the first George Fisher Baker, a group of buildings erected for the Law School by Myron

C. Taylor, a large bequest from John McMullen for scholarships in engineering, funds for student residential halls, and a social centre for students and faculty given by Mrs. Leonard Elmhirst in memory of Willard Straight.

The university in 1938–39 had $33,202,900 in productive funds. Its income available for operating expenses was $10,071,000, including $3,285,432 in State and $869,541 in Federal funds. Gifts amounting to $1,009,450 were received during the year. Its lands and buildings were valued at $19,541,700 and its equipment at $8,200,950. The library contained upwards of a million volumes. Teachers, exclusive of assistants and extension workers, numbered 1,078 and 7,055 students were enrolled. The university's lands including farms, forests, and other experimental tracts aggregated 6,646 acres.

CORNER, a commercial term used in England and the United States to signify the control of so large a supply of an industrial or commercial product or of so much of a stock that the market value of the commodity held is tremendously advanced, and those who have made contracts to deliver the stock or commodity in question must buy at the prices set by the pool. So the actual difference between the manœuvre of the corner-man and the normal effort to bull prices by controlling supply is that the corner is based upon knowledge of contracts made for future delivery by those who are not in present possession of the stock. In stock exchange parlance a «corner» is procured where somebody succeeds in buying for further delivery more property of a given kind than is possible for the seller to deliver before the day of the maturity of the contract. The term is used in boards of trade, etc., to designate the condition arising when a much greater quantity of any given commodity is sold for future delivery within a given period than can be purchased in the market. The buyers, who are called in the slang of the exchange «longs,» then insist on delivery, and by these means succeed in running up prices to a fictitious point, by which deals are run out between the dealers, or by exchanges, or, where the person insists upon it, by actual delivery. A very large majority of these transactions are no doubt merely speculative, but many of them are actually purchases for manufacturers and exporters. Successful corners depend then not only on a thorough understanding of where the control of the commodity in question lies, lest another holder at the critical moment be able to undersell the would-be corner-man, but on the willingness of the buyer to keep his contracts at no matter what cost. In other words, if the corner-man is too greedy and demands too high a price, buyers may smash the corner by refusing to keep their contracts, a procedure with a certain amount of poetic justice in it, at least when the members of the corner have gained control of the supply which they are to rebuy from the contractors. Legally defined, a «corner» is the securing of such control of the immediate supply of any product as to enable those operating the corner to advance arbitrarily the price of the product. It is created ordinarily by operations on boards of trade or stock exchanges, and by dealings in options and fixtures. A «corner» when accomplished by a confederation to raise or depress prices and operate on the market is a conspiracy if the means employed are unlawful. Cereals and cotton, because of the large amount of future trading done in them, are favorite fields for the corner-man; but the exact amount of a year's crop and the thorough location of such holdings make the manœuvre particularly dangerous. Typical «corners» of ancient history include: Joseph's buying and storing the corn of Egypt, so that «all countries came to Joseph to buy corn» (Gen. xli, 57); and the Athenian corner in grain, orated against by Lysias (d. 380 B.C.). Many of the worst financial panics in the United States have been the results of attempts, usually unsuccessful, to corner the gold market. The greatest of these was that which culminated in Black Friday, 24 Sept. 1869, through the operations of Jay Gould and James Fisk, Jr. Consult Boutwell, G. L., 'The Mint Bill and the Crime of 1873' and 'Black Friday' (Chaps. 34–35 in Vol. 2, 'Reminiscences of Sixty Years in Public Affairs,' New York 1902); and Lysias, 'Against the Grain Dealers'; also of allied interest 'On the Sacred Olive' (orations 22 and 7 in 'Ten Selected Orations' edited by G. P. Bristol, Boston and Chicago 1892).

CORNET (Fr. «little horn»), formerly a reed wind instrument of the oboe class; but the name cornet or *cornet-à-pistons* is now given to a brass musical instrument with a cup-shaped mouthpiece, which has a very agreeable tone, and is much used in orchestras and military bands, and sometimes with organ in church music. The cornet is intermediate in character between the French horn, the trumpet and the bugle. Its characteristic feature is its three pistons, which may be pressed down by the fingers singly or together, so as greatly to increase its compass. The first lowers the pitch by a tone, the second by a semitone, the third by three semitones. Its range is from C^1 to C^3. In brass bands it takes the soprano and contralto parts. The name was also applied to the stop or series of pipes in an organ, intended to imitate the tone of an obsolete wind instrument which has been superseded by the oboe.

From its military use the term cornet was transferred to a cavalry troop, because it was accompanied by a cornet player, and then to the color officer of this troop, the cornet of cavalry corresponding to the infantry ensign. This title of the English army was abolished in 1871, the rank of sub-lieutenant taking its place.

CORNETO, kōr-nā'tō, or **CORNETO TARQUINIA**, Italy, a picturesque, mediæval-looking town, situated 12 miles north of Cività Vecchia, three miles from the Mediterranean, on the Marta River. Corneto is the seat of an episcopal see. It rose out of the ruins of the Etruscan city of Tarquinii, whose remains, within a mile and a half of Corneto, are among the most important for the student of Etruscan history. It seems to have been destroyed by the Saracens. The Necropolis of Tarquinii, the most important relic of the ancient city, is on the same hill as the modern city and extends into the neighboring plain. It covers about 16 square miles. The painted tombs, of which some 20 are specially interesting, were known in the 18th century; but it is mainly since 1842 that they have been examined; valuable new discoveries were made during excavations in 1881–82. Pop. about 7,000. Consult Dennis,

'Cities and Cemeteries of Etruria' (London 1907); Dasti, 'Notizie di Tarquinia e Corneto' (Rome 1878); and the periodical *Notizie degli Scavi* (1906–07).

CORNFLOWER, or **BLUEBOTTLE** (*Centaurea cyanus*). A plant of the Compositæ family, indigenous to Europe. It develops long slender, branched stems, from 12 to 30 inches high, and with a flower about one and one-half inches in diameter. It is a hardy plant and is popular in American flower gardens. There are many varieties and the color ranges from deep blue to white.

CORNHILL, London, one of the principal streets of the city, once a corn market. In mediæval times two of its attractions were the Tun, a round house used as a temporary prison, and the Standard, a water conduit and also a point of measurement.

CORNICE (It. "cornice"), **LA CORNICHE,** or **CORNICE ROAD,** a famous highway between France and Italy, skirting the Mediterranean from Nice to Genoa. The word cornice means literally "shelf," in allusion to the fact that for miles the road is cut in the face of the cliffs. The modern road was begun by the French and finished by the Sardinian government after the fall of Napoleon.

CORNICE, in architecture, the uppermost of the three parts of an entablature, composed of the projected moldings of the roof. The Egyptian form was a high cavetto or fillet above a round bend. Three styles are known in Greek architecture: The Doric cornice consists of a Doric cyma, the corona projecting considerably, and containing the ends of the roofing boards, a second cyma and an erect bell molding. The Ionic cornice shows a fillet either with dentals or quite plain, above which are a wave molding and the corona, terminating in a slab and erect bell molding. The Corinthian cornice differs from the Ionic in having small consols, composed of volutes and acanthus leaves. In Gothic architecture the cornices are often elaborately adorned with animals or with human figures. In Romanesque buildings, an arcaded cornice was developed, resting on corbels without arches or moldings. The Renaissance revived the classic type. It is used now as a projection on the top of a wall, which is used to throw off the rain water from the roof.

CORNING, Erastus, American capitalist: b. Norwich, Conn., 14 Dec. 1794; d. Albany, N. Y., 9 April 1872. He became a prominent iron merchant in Albany, N. Y., subsequently engaged in the banking business, and applied much of his time and means to the development of the railroad system of New York State. He effected the consolidation of various roads into the New York Central Railroad, and was its president 12 years; was State senator 1842–45; member of Congress 1857–59 and 1861–63; member of the Peace Congress in 1861, regent of the University of New York in 1833, and vice-chancellor of the board.

CORNING, James Leonard, American physician: b. Stamford, Conn., 26 Aug. 1855; d. Morristown, N. J., 25 Aug. 1923. He studied at Heidelberg and Würzburg in Germany, and was graduated at the latter. He had an international reputation as an expert neurologist, and as the discoverer of spinal anæsthesia (1885). He was the first to inject liquid paraffin into the tissues, there to solidify; he also demonstrated that the action of stimulants, sedatives and certain other medicinal substances may be increased if the subject remains in compressed air. As consulting neurologist he served various New York hospitals and, besides his contributions to the medical press, wrote 'Carotid Compression' (1882); 'Brain Rest' (1883); 'Local Anæsthesia' (1886); 'Hysteria and Epilepsy' (1888); 'Treatise on Headache and Neuralgia' (1888); 'Pain in Its Neuro-Pathological and Neuro-Therapeutic Relations' (1894); 'Experimental Researches Regarding the State of the Mind in Vertigo' (1895). Under the pseudonym of Roland Champion he wrote a romance entitled 'Princess Ahmedee' (1900)

CORNING, Iowa, city and Adams County seat; alt. 1,117 feet; on the Nodaway River; 78m. SE. of Council Bluffs; on the Burlington Railroad. In an agricultural region with coal and limestone deposits, it manufactures brick and tile. Platted in 1855, it became the trading point for the Icarian Community (1858–98) of the French followers of Etienne Cabet (q.v.). Named after the founder of Corning, N. Y., it became a city in 1871. Pop. (1940) 2,162.

CORNING, N. Y., city and seat of Steuben County, alt. 937 feet, 20 miles northwest of Elmira, on the Chemung River, the Erie, the New York Central, and the Lackawanna railroads and on one federal and two state highways. It is near Painted Post, once an Indian village, and Watkins Glen, a tourist resort. Notable buildings in the city are the courthouse, the city hall, the Corning Free Academy, the stone clock tower erected in 1884 in honor of Erastus Corning, for whom the city was named, and the Civic Observatory Museum, which houses a duplicate of the 200-inch mirror disk made here for the California Institute of Technology. Corning is called the Crystal City. It manufactures many kinds of glass—ovenware, bulbs, tubing, glassware, lenses, radio tubes, glass, wool—fiber boxes, pneumatic tools, saws, furnaces, castings. Coal mining, dairying, and tobacco raising give Corning a trade in these staples. Corning was settled as early as 1789, was incorporated as a village in 1848, as a city in 1890. Corning has a mayor-and-council government. Pop. (1940) 16,212.

CORNISH, Charles John, English naturalist: b. Salcombe House, Devonshire, 28 Sept. 1858; d. 30 Jan. 1906. He was educated at the Charterhouse and Hertford College, Oxford, and for many years was a regular contributor to *The Spectator* and *Country Life* on natural history and outdoor life. His published books include 'The New Forest' (1894); 'The Isle of Wight' (1895); 'Life at the Zoo' (1895); 'Wild England of To-day' (1895); 'Animals at Work and Play' (1896); 'Nights with an Old Gunner' (1897); 'Animals of To-day' (1899); 'The Naturalist on the Thames' (1902).

CORNISH LITERATURE. The ancient language of Cornwall formed with Welsh and Breton the Cymric or southern division of the Celtic Languages (see CELTIC LANGUAGES; CELTIC LITERATURES) and more closely resembled the Breton than the Welsh. It was generally spoken until the time of Queen Elizabeth.

Its decay dates from the Reformation, and was due to the failure of the Church of England to translate the Book of Common Prayer and the Bible into the language of the province. After 1678 it ceased to be used in public worship. Dolly Pentreath of Mousehole (1676–1771) is reputed to have been the last person to have spoken it wholly; but words and phrases have come down which are still in use. Its vocabulary dates probably from the 13th century; and the sacred dramas that survive are not earlier than the 14th century. Consult Norris, 'Ancient Cornish Drama' (1859); Stokes, 'Mystery of Creation' (1864); 'Glossary of Cormac' (1864); edition of 'Life of Saint Meriasek' (1872); Jago, 'Ancient Language of Cornwall' (1882); 'English-Cornish Dictionary' (1887); Williams, 'Lexicon Cornu-Britannicum' (1865) and supplementary to the last named, Loth's 'Remarques et corrections' (1902); Jenner, 'Handbook of the Cornish Language' (1904).

CORNSTALK, chief of the Shawnee Indians: b. about 1720; d. 1777. He was a man of high abilities and dignity of character. He first appears as heading the Greenbriar massacre of July 1763, in Pontiac's war; next in a far higher rôle, as commanding the Indian forces at the bloody and hard-fought battle of Point Pleasant, 10 Oct. 1774, in Dunmore's war. (See COLONIAL WARS). He had opposed the war, being convinced that it meant ultimately swifter ruin for the Indians; but once embarked, he fought with a skill and resolution that excited the admiration of his enemies. After the defeat he was in favor of carrying on the war to the end; but finding his head men and subchiefs determined on giving up, he went himself to make the best terms he could. His oratory was said by the Virginians to equal Patrick Henry's. Early in 1777 he came with his son and two other Indians to the garrison at Point Pleasant, to tell them that, although he wished to keep the peace, his tribe was resolved on war, and if so, he must join them. The party were held as hostages; but one of a company of rangers being killed by Indians near by, the rest and their captain rushed to the fort and butchered the four, Cornstalk rising to meet his fate without a word.

CORNUS. See CORNEL; DOGWOOD; TUPELO.

CORNWALL, Duke of, a hereditary title of the eldest son of the sovereign of Great Britain. Cornwall is a royal duchy, the revenues of which belong to the Prince of Wales for the time being. The title of Prince of Wales is conferred by special creation, that of Duke of Cornwall descends by inheritance. The dukedom of Cornwall was created for the Black Prince in 1337.

CORNWALL, Barry. See PROCTER, BRYAN WALLER.

CORNWALL, Henry Bedinger, American chemist: b. Southport, Conn., 29 July 1844; d. 1 April 1917; graduated at Columbia 1864, and from its school of mines 1867, becoming assistant in the latter 1865–73, save for two years' study at the mining school in Freiberg, Germany. In 1873 he was appointed professor of applied chemistry and mineralogy at Princeton University, and in 1910 became emeritus professor. With Caswell, he translated Plattner's 'Manual of Qualitative and Quantitative Analysis with the Blow-pipe' (1875), and wrote 'Manual of Blow-pipe Analysis, with a System of Determinative Mineralogy' (1882), and many scientific papers that appeared in the special journals of his profession.

CORNWALL, Canada, port of entry, and capital of the three united counties of Stormont, Dundas and Glengarry in Ontario, and is situated on the St. Lawrence River, also the C. Natl., C. Pac. and N. Y. Central railways. It has admirable shipping facilities, and is 67 miles west of Montreal, 56 miles from Ottawa and 50 miles from the Adirondacks. It has eight churches, Anglican, Roman Catholic, Presbyterian, United, and one Salvation Army barracks. There are three hospitals, six schools, a collegiate institute and numerous banks and public buildings. It has large textile industries, paper, pulp, flour and planing mills, machine shops and foundries, and manufactories of bedding, chairs and other furniture. Building stone is quarried in the neighborhood. The city is in a rich agricultural section and has a large trade. The United States is represented by a consular agent. It has two newspapers and is lighted by electricity. Pop. (1931) 11,126.

CORNWALL (Lat. *Cornu Galliæ,* "horn of Gaul," that is, the remotest land inhabited by Celts), England, a maritime county, forming the southwestern extremity of the island. Its form is irregularly triangular. Its area is 1,357 square miles. The northwestern coast-line is broken by a number of shallow bays. The south coast is much more broken, and is marked both by bolder promontories and deeper bays. At Land's End, between these two coasts, terminate the hills of the Devonian range. The rivers of Cornwall are numerous but short. Among them are the Fowey, the Camel, the Inny, the Attery, the Lynner, etc. The climate, owing to the elevation and exposure of the surface, is very variable. The soil, consisting of decomposed slate, admits of easy drainage, but requires much manure. In many of the more elevated districts much of the land is almost barren. Nearly 70 per cent of the total area is under cultivation, a large amount of grain being grown, and much land being devoted to market-gardening for London consumption. Cattle, sheep and horses are reared. The mines of copper and tin, famous for many centuries, and known to the Phœnicians, still constitute the richest treasures of the county, though the value of both has greatly diminished. The chief mining district is in the southwest part of the county. Several mines exceed 350 fathoms in depth. In the once productive Botallack copper mine, situated a few miles north of Land's End, the workings are on the very verge of the cliff, and, descending beneath the sea, are carried far beyond low-water mark. The Dolcoath mine, near Camborne, is the chief tin mine, and there are other important tin mines in the same locality. The production of copper has greatly decreased in recent times. China-clay is an important mineral product. Owing to depression in the mining industry, there has been considerable emigration to the silver mines of Nevada, and to other mining centres. There are few manufactures, but the fisheries, par-

ticularly of pilchard and mackerel, are valuable. The dukedom of Cornwall is always held by the eldest son of the sovereign, to which valuable estates are attached. At the time of the Roman conquest Cornwall was occupied chiefly by tribes of Cimbri and Damnonii, and became included in the province of Britannia Prima. After the Romans withdrew the natives regained their independence and retained it till the time of Athelstane, when they were subdued by the Saxons. Their Celtic origin is fully established by the abundance of rude monuments spread over the country, and consisting chiefly of unwrought stones placed erect, singly or in circles, with others laid across. It is divided for parliamentary purposes into six divisions, each returning one member. Pop. 320,705. Consult Boase, 'Bibliotheca Cornubiensis' (1874–78).

CORNWALL, or **CORNWALL-ON-HUDSON,** N. Y., village in Orange County, alt. 167 feet, at the foot of Storm King Mountain on the west shore of the Hudson River, opposite Mount Beacon; on the New York, Ontario and Western and the West Shore railroads, 53m. N. of New York. In addition to railroad service, it has transportation by river steamer. In the midst of farm lands and forests, it has paper and carpet mills. There are a public library and a general hospital, and three preparatory and military schools. N. P. Willis, poet of Knickerbocker times in New York, and the novelists, Amelia E. Barr and E. P. Roe (qq.v.) wrote at Cornwall. Settled in the 1680's, it was incorporated in 1885. The village government is administered by a mayor and board of village trustees. The water system is municipally-owned. Pop. (1940) 1,978.

CORNWALL CANAL. See CANADIAN CANALS.

CORNWALLIS, Caroline Frances, English author: b. Kent, 12 July 1786; d. Lidwells, Kent, 8 Jan. 1858. She acquired a thorough knowledge of Latin and Greek, and making herself conversant with nearly every study which occupies thoughtful men, from an early age, carried on a correspondence with many eminent persons. Her refusal to accept the hand of the Italian historian, Sismondi, did not forfeit his friendship, and she lived much in Italy. Her first work, 'Philosophical Theories and Philosophical Experience, by a Pariah' (1842), was the first of a series of 20 'Small Books on Great Subjects,' the said subjects including the 'Connection of Physiology and Intellectual Science'; 'Ragged Schools'; 'Criminal Law'; 'Greek Philosophy,' and the 'History and Influence of Christian Opinions.' Twenty-two volumes of this series appeared between 1842–54, all the most important of which were written by herself. She also published in 1847 'Pericles, a Tale of Athens,' and her 'Letters and Remains' appeared in 1864.

CORNWALLIS, Charles, 1ST MARQUIS and 2D EARL, English general: b. London, 31 Dec. 1738; d. Ghazipur, Benares, India, 5 Oct. 1805. He was educated at Eton and Cambridge, and entering the army served in 1761 in a campaign of the Seven Years' War as aide-de-camp to the Marquis of Granby. After passing through all the various promotions he obtained the rank of general. He represented the borough of Eye in Parliament from 1760 until the death of his father in 1762, when he succeeded as Earl Cornwallis. In 1770 he was made governor of the Tower. In Parliament he generally supported the ministry, but exercised an independent judgment on several important questions. In particular he was opposed to the policy which brought on the American war; but though offered a special leave of absence from the king sailed with his regiment when it was ordered to America in 1776. He served with distinction under Generals Howe and Clinton in the campaigns of 1776–79 in New York and the Southern States, and in 1780 was left in independent command in South Carolina, with 4,000 men. He defeated General Gates at Camden 16 Aug. 1780, and General Greene at Guilford 15 March 1781. He then invaded Virginia, but after moving his forces according to successive and contrary instructions from Sir Henry Clinton, he was besieged in Yorktown, where he had entrenched himself, and compelled to surrender on 19 Oct. 1781. In 1786 Lord Cornwallis was sent to India with the double appointment of commander-in-chief and governor-general; and not long after the government of Bengal declared war against the Sultan of Mysore for an attack upon the Rajah of Travancore, the ally of the British. The first campaign was indecisive; but in March 1791, he invaded Mysore, captured Bangalore; and in the year after besieged the city of Seringapatam, and obliged the sultan, Tippoo Sahib, to sue for peace, and surrender a large portion of his dominions. On the conclusion of the war Lord Cornwallis returned to Great Britain, and in 1792 was created marquis, appointed master-general of the ordnance, and admitted a member of the privy council. In 1798, at the time of the rebellion, he was appointed lord-lieutenant of Ireland, which office he filled until 1801, conducting himself with great firmness and judgment. In the same year he was sent as plenipotentiary to France, where he signed the Peace of Amiens. In 1804 he was again appointed governor-general of India. Consult Marshall, 'Memoir' (Gateshead 1806); Lord Cornwallis, 'Correspondence' (edited by Ross, London 1859); Seton-Karr, "The Marquess Cornwallis" (in 'Rulers of India,' Oxford 1890).

CORNWALLIS, Edward, English soldier and colonial administrator: b. 1712. He entered the army, and was present at the battles of Fontenoy and Prestonpans. He was the first governor of Nova Scotia, 1749–52, and the founder of Halifax. He sat in the House of Commons for Eye, 1749, and for Westminster, 1753. He was subsequently governor of Gibraltar.

CORNWALLIS, Kinahan, American lawyer, editor, novelist, poet: b. London, England, 24 Dec. 1839; d. 15 Aug. 1917. Educated for the ministry of the Church of England, also at Collegiate Institution, Liverpool; later he studied at the School of Medicine, Liverpool, and Trinity College, but was then appointed to a British government post in Australia, and resided two years at Melbourne. He then returned to London and published there 10 volumes of his travels, novels and poems; was appointed to a post in British Columbia, resigned his British appointment, and soon afterward went

to Washington as correspondent of the New York *Herald* with the newly arrived first Japanese Embassy to the United States, on an American warship. Then he went to the British provinces, and met the Prince of Wales on his arrival, and as the *Herald's* correspondent accompanied him everywhere till his departure for England in October. In November 1860 he published in New York and London his book of the tour 'Royalty in the New World; or The Prince of Wales in America.' He became Charles Reade's agent in America. Mr. Cornwallis remained on the *Herald* as financial editor and editorial writer nearly 10 years, and meanwhile bought and edited the old *Knickerbocker Magazine.* When he left the *Herald* he also bought and then edited *The Albion,* a weekly newspaper. In 1880 he established *The Wall Street Daily Investigator,* which he thereafter owned and edited for 25 years, at the same time practising law, having been naturalized, and admitted to the New York bar in May 1863. He had published the following books in London prior to 1860: 'An Australian Poem—Yarra Yarra'; 'Two Journeys to Japan' (2 vols.); 'A Panorama of the New World' (2 vols.); 'The New Eldorado, or British Columbia'; all the result of travel; also three novels — 'Howard Plunkett, or Adrift in Life' (2 vols.); 'Wreck and Ruin, or Modern Society' (3 vols.); and the 'Gittens Family: A Medley.' In 1861 appeared his 'Pilgrims of Fashion'; and 'Adrift with a Vengeance'; and 'A Marvellous Coincidence' followed. Then came two descriptive poems of one volume each embodying the history of America from the time of the Norsemen to the Civil War; viz., 'The Song of America and Columbus'; and 'The Conquest of Mexico and Peru,' to which a third volume was added later — 'The War for the Union, or The Duel Between North and South.' 'The History of Constructive Contempt of Court' while other publications on law and many magazine and newspaper articles and poems were also published by him here and in British periodicals. He was the oldest in membership in the Saint George's Society of New York.

CORO, kō'rō, or **SANTA ANA DE CORO,** Venezuela, town in the state of Falcon, near the Gulf of Coro, an inlet of the Gulf of Maracaibo, two and a fourth miles from the Caribbean Sea, on which is its port, Vela de Coro, about seven miles distant by railway. The trade was once considerable, but has now much fallen off; as is also the town since 1578, when the seat of government was transferred from it to Caracas. Coro contains several churches, interesting for their antiquity, though they either have been rebuilt or lie in ruins. La Vela, its port, has a good harbor and a trade with the Dutch West Indies and is the residence of a United States consular agent. Coro, one of the oldest cities in Venezuela, was settled by Juan de Ampués in 1527 and for a time was the Spanish capital of Venezuela. It was created the first bishopric of Venezuela in 1531, but subsequently the see was removed. It was the objective point of Miranda's first descent upon Venezuela in 1805, when he led an abortive expedition against the Spanish in the hope of precipitating the revolution of the Spanish-American colonies. Pop. 9,000.

COROADOS, kō-rō-ä'dōz, Indians of Brazil, the name being derived from their tonsures, just as the name Botocudo is applied to other aborigines of the same country who wear botogues or labrets. It is an arbitrary collective title for ethnic fragments whose tribal names have been lost. Tribes thus designated are found at the present day in some of the southern states of Brazil, especially in Paraná, Rio Grande do Sul, São Paulo and Matto Grosso; but only a few thousands remain in scattered groups, evidently representing different stages in development, though in a general way the Indians of the upper Paraná and upper Paraguay region may be classified as true aborigines, "the nearest representatives, and probably the direct descendants, of that primitive race whose osseous remains have been found in Lagoa Santa caves and Santa Catarina shell mounds." Consult Keane, 'Man, Past and Present'; Porter, 'Native Races.'

COROLLA, kō-rŏl'a, the inner whorl of two series of floral envelopes, occurring in the more highly developed plants, the outer being the calyx. In all cases its divisions, which are called petals, alternate with those of the calyx. They are generally colored — that is, they are some other color than green. The corolla is, as a rule, larger than the calyx. When the petals of a corolla are all distinct, they are said to be polypetalous, and this is the normal type. When they cohere continuously by their margins they are called monopetalous, or, better, gamopetalous, meaning that the petals are joined. The petals of a corolla are really only modifications of leaves. The corolla merely assists reproduction by shading the productive organs from injury, and, in some cases, by secreting honey attracts bees and other insects to aid in their fertilization.

COROLLARY (Lat. "crown," or "garland," and in a derived sense "gift"; hence something given or granted), in logic, a proposition the truth of which appears so clearly from the proof of another as not to require separate demonstration.

COROMANDEL COAST, the east coast of the Indian Peninsula, between Calimere Point and the mouths of the Kistna. It is open, sandy and has no secure harbors; the surf, continually beating on it, renders landing difficult, often dangerous, and it is commonly accomplished in native boats of a peculiar construction. A violent monsoon accompanied by hurricanes blows from the middle of October well into April.

CORÕN, kô-rōn', Philippines. See PEÑON DE CORÓN.

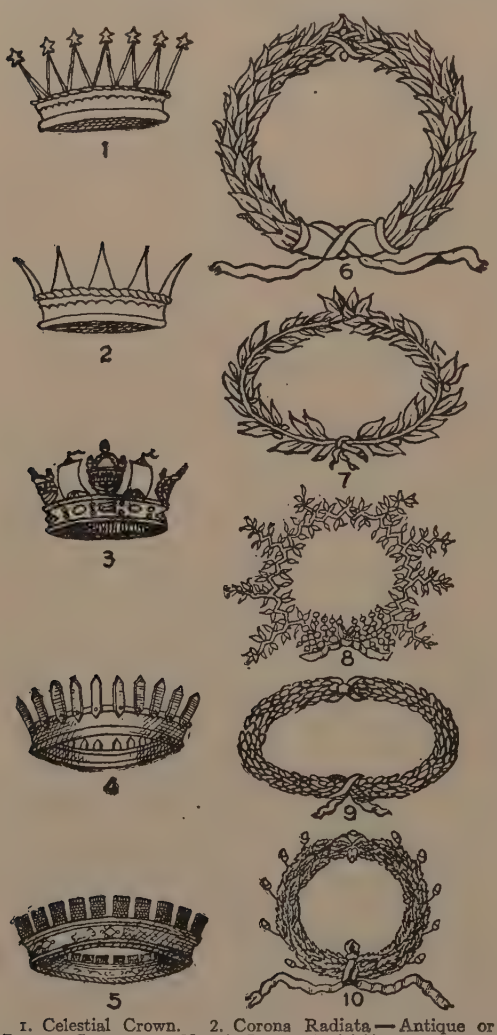
CORONA, Calif., city in Riverside County, alt. 700 feet, on the Santa Fe and the Pacific Electric railroads, 50m. SE. of Los Angeles. It packs and ships citrus fruits and handles clay products and silica sand. Settled in 1898, it was incorporated as a city in 1906. It has a mayor and council, and the water, power, and light services are privately operated. Pop. (1930) 7,018; (1940) 8,764.

CORONA. The crown of victory, termed *corona,* of the ancient Greeks and Romans, was what we, in this day, term a wreath. These coronæ come under the following classes: Those

dedicated to the victors in peaceful contests and those voted for military achievement.

The crown or garland of the victor in the Olympian and the Pythian games was of laurel, that of the winner in the Nemean contests consisted of oak leaves, that of the Isthmian games was made from the pine tree.

The Roman coronæ were mostly military and termed «triumphal.» The most important were: *Celestial crown,* similar to the *Eastern crown* (see below), but having each *ray* surmounted by a small star. *Civic crown* (*corona civica*), composed of acorns and oak leaves, given as reward for saving a citizen's life in battle. *Eastern crown,* often termed *antique crown* (*corona radiata,* usually carries, above the gold circle, eight *rays*), is the Roman crown of apotheosis, but Great Britain has used it to honor successful statesmen in India and her Eastern dependencies, hence the term Eastern. *Laurel crown* (*corona laurea*), originally a martial crown, became a wreath of honor and distinction on civic occasions, and was composed of laurel leaves on their stem. *Myrtle crown* (*corona myrtea*), composed of myrtle leaves (myrtle was dedicated to Venus), was awarded to conquerors and used in wedding ceremonies, also placed upon the heads of the dead. *Mural crown* (*corona muralis*) was a circle of gold surmounted by pinnacles or battlements given for great prowess in scaling a wall and attacking the town within. *Naval crown* (*corona navalis* or *rostrata*) was a circle of gold surmounted by prows (*rostra*) of boats awarded to victorious sea warriors (the British nation also uses a naval crown composed of a gold rim surmounted by four ships' sterns and four sails alternating). *Obsidianal crown* (*corona obsidianalis* or *graminea*), composed of herbs or grass, awarded to a general who delivered a town from a state of siege. *Olive crown* (*corona oleagina*), composed of olive leaves, was a crown of martial victory, the olive tree being dedicated to Minerva. *Triumphal crown* (*corona triumphalis*), composed of *single* laurel leaves closely compact. *Vallary crown* (*corona vallaris* or *castrensis*), composed of a circle surmounted by palisadoes, was the honor conferred on the first warrior to pass the enemy trenched wall (*vallum*) or fence and enter the foe's camp or fortress (*castrum*).



1. Celestial Crown. 2. Corona Radiata — Antique or Eastern Crown. 3. Naval Crown (British). 4. Corona Vallaris. 5. Corona Muralis. 6. Corona Triumphalis. 7. Corona Laurea. 8. Corona Graminea or Obsidianalis. 9. Corona Myrtea Ovalis. 10. Corona Civica.

Among the ancient religious ceremonial crowns were the *coronæ funebres* or *sepulchres,* funeral chaplets of leaves and flowers; the *corona convivialis,* worn at banquets, etc., and the *corona natalis,* suspended over the door where a birth had taken place (at Athens olive for a boy, wool for a girl). The *nuptial crown* (*corona nuptialis*) was composed of flowers (verbena preferred) plucked by the bride herself. See Crowns and Coronets.

Clement Webber Coumbe.

CORONA (a crown), *in astronomy,* a halo or luminous circle round one of the heavenly bodies; specifically the portion of the aureola observed during total eclipses of the sun, which lies outside the chromosphere or region of colored prominences. (See Halo). *In botany* the corona is an appendage of the corolla in some flowers, coming as it were between the corolla and the stamens, well seen in the cup of the daffodil. *In architecture* it is the lower member of the projecting part of a cornice.

CORONA AUSTRALIS (the southern crown), one of Ptolemy's southern constellations, containing 49 naked-eye stars, varying from the third to the seventh magnitude.

CORONA BOREALIS (the northern crown), one of Ptolemy's northern constellations, situated near Hercules, and containing about 30 stars visible with the naked eye; *α*, known as Gemma, is of the second magnitude, the chief of a curved row of seven stars of the third, fourth and fifth magnitudes. In 1866 a new star of the second magnitude appeared in the constellation, but soon after became invisible save with a glass.

CORONACH. See Coranach.

CORONADO, kō-rō-nä'dō, Francisco Vasquez de, Spanish explorer: b. Salamanca, Spain, about 1500; d. Mexico after 1542. He came to the New World about 1535, and by marrying the daughter of Estrada, the royal

treasurer for New Spain, was appointed governor of the province of New Galicia. On the arrival in Culiacan of Alvar Nuñez, Cabeça de Vaca, from his extraordinary journey from Florida in the year 1536, when he brought news of the existence of half-civilized tribes far to the north, living in populous cities, acquainted with the arts, and possessing quantities of gold, silver and precious stones, an expedition was sent out under Marco de Niza, in 1539, to explore the regions referred to. The result tended to strengthen the belief in the existence of great wealth among the nations far to the north, and a second expedition was fitted out under Coronado, which departed from Culiacan, on the Pacific Coast, in April 1540. He passed up the entire length of what is now the Mexican state of Sonora to the river Gila. Crossing this he penetrated the country beyond, to the Little Colorado (called by him Rio del Lino), and paid a visit to the famed cities of Cibola mentioned by Cabeça de Vaca and De Niza. In the kingdom were seven cities, but he declares that there was no truth in the reports of his predecessors regarding their wealth. "All was quite the contrary," he adds, "saving only the names of the cities and great houses of stone." From Cibola, Coronado traveled eastward, visiting several towns occupied by a similar people to those he had met, which are recognized in the existing villages of the present Pueblo Indians. He proceeded eastward to what he calls the "big river," which is the Rio Grande, where he heard of the great city of Quivira. In their journey eastward they "met with a new kind of oxen, wild and fierce, whereof, the first day, they killed fourscore, which sufficed the army with flesh." They continued to Quivira, almost 300 leagues distant, by their account, traversing "mighty plains and sandy heaths, smooth and wearisome, and bare of wood." Coronado's narrative is of value as it furnishes the first authentic account of the buffalo, the great prairies and the desert plains of New Mexico. It describes, too, with every appearance of truth, the towns of the Pueblo or semi-civilized tribes of Indians, as they existed more than 300 years ago, and which are still found in New Mexico. He returned to Mexico with such of his army as had not deserted along the route. The viceroy received him coldly and allowed him to resign the government of New Galicia. He lived quietly on his estates until his death. Winship translated the original documents, published in 1896; consult also his 'Journey of Coronado' (New York 1904).

CORONADO, Calif., a resort and residential city of San Diego County, on San Diego Bay, alt. 25 feet. Pop. (1940) 6,932.

CORONATION, the ceremonial rite of placing a crown on the head of a monarch as a symbol of his assumption of rule. The practice is one of great antiquity and in most countries has been followed in some form or other. Accompanying the crowning has been the anointing with oil, a custom that was followed in the dedication of the Hebrew kings, and is significant of consecration to the will of God. In England before the Norman Conquest the term employed was more "hallowing" than "coronation." Egferth, Prince of Mercia, was "hallowed king" by Offa, his father, in 785; and the essential form of words employed has been altered little in the 12 centuries that have intervened; but various parts of the service employed in later times have been shortened and some omitted altogether. Thus the ceremonial, in the earlier days of the English monarchy performed at Kingston-on-Thames or Winchester, is in essentials the same as that now performed at Westminster. The recognition of the king as rightful lord is followed by a sermon, the anointing, the presentation of the ring as the symbol of kingly dignity and of the sceptre as the symbol of kingly power, the crowning, the presentation of the Bible, the enthronization, the homage. The service is one in which the religion of the nation is asserted; the covenant is one between God, the king and his people. In addition to anointing, the kings prior to the Reformation were signed on the head with chrism or sacred oil; and touching for the kings evil or scrofula was practised until the accession of the House of Hanover in 1714.

The ancient Scottish coronation stone — the Stone of Destiny — forms part of the coronation chair at Westminster. It was brought from Scone, where the Scottish kings were crowned, by Edward I in 1296. It is traditionally believed to have been the stone which Jacob used for a pillow, to have been brought to Ireland and from Tara, the site of the Irish coronations, to Scone; but the unimaginative Skene says that from its geological composition it must have been quarried from rocks near Scone.

There have been variations in the oath taken from time to time. The declaration which was introduced in 1678 under the excitement produced by the so-called Popish Plot continued almost unabated down to the time of the coronation of the late George V, 22 June 1911. That oath, aimed at securing a Protestant sovereign and the safeguarding of the Protestant Succession, expressly repudiated two cherished doctrines of the Roman Catholic Church — invocation of the Virgin Mary and the saints and transubstantiation. Subscription to this oath was given as the reason by George III and George IV why they would not consent to Catholic emancipation. King Edward VII wished to be relieved from that part of the oath which was offensive to his Catholic subjects; but an attempt at emendation before his coronation fell through. The subject was again brought up before the crowning of George V, and by the Accession Oath Act of 1910 the objectionable phrases were withdrawn, and the king simply pledges himself as a "faithful member of the Protestant Reformed Church of England," to secure the Protestant succession "according to law."

In honor of Charlemagne, the emperors of Germany were always crowned at Aix-la-Chapelle, in the church which he founded. Thirty emperors were crowned there, and until 1793 the regalia and robes were preserved there. The kings of France were crowned at Rheims and their queen consorts at the church of Saint Denys, near Paris; those of Spain, at Toledo or Madrid; of Poland, at Guezna; of Hungary, at Pressburg; of Scotland, at Scone; and the native kings of Ireland, at Tara. The recent kings of Denmark have been crowned at Fredericksburg; those of Sweden at Upsala, and the emperors of Russia, at the Kremlin, Moscow. Consult Johnston, W. F., 'The Coronation of a King; or, Ceremonies, Pageants and Chronicles of the Coronations of All Ages'

(London 1902); and Perkins, Jocelyn, 'The Coronation Book; or, the Hallowing of the Sovereigns of England' (London 1911).

CORONATION CHAIR, the ancient throne in Westminster Abbey used at the coronation of English kings since Edward I. Beneath the seat is the Lia Fail, or Stone of Destiny, on which Scotland's kings were crowned. The stone is said to have been used by Jacob as a pillow, and to have been in Tara, the residence of the high kings of Ireland, after the 5th century B.C. It was brought to Scotland many centuries later and thence to England by Edward I. Celtic tradition has it that political supremacy goes to the people in whose territory the stone rests.

CORONATION GULF, an inlet on the northern coast of British America into which empty the waters of the Coppermine River. It is north of the Arctic circle and included between long. 107° and 116° W. Bathurst Inlet is an extension toward the southeast. It is connected with other Arctic channels by Dease Strait on the northeast and Dolphin and Union Strait on the northwest. It is studded with islands.

CORONEA, kŏr-ō-nē'a, a small town of Bœotia (q.v.), southwest of Lake Copias, where in 447 B.C. the Bœotians defeated the Athenians and became the leading state of Greece; and in 394 Agesilaus defeated the allied Greeks. The town is now in ruins.

CORONEL, Chile, a port in the province of Concepción, on the Araucobai River, important on account of its coal mines. The customs receipts average about 700,000 pesos per annum. It is a coaling station. Pop. 14,000.

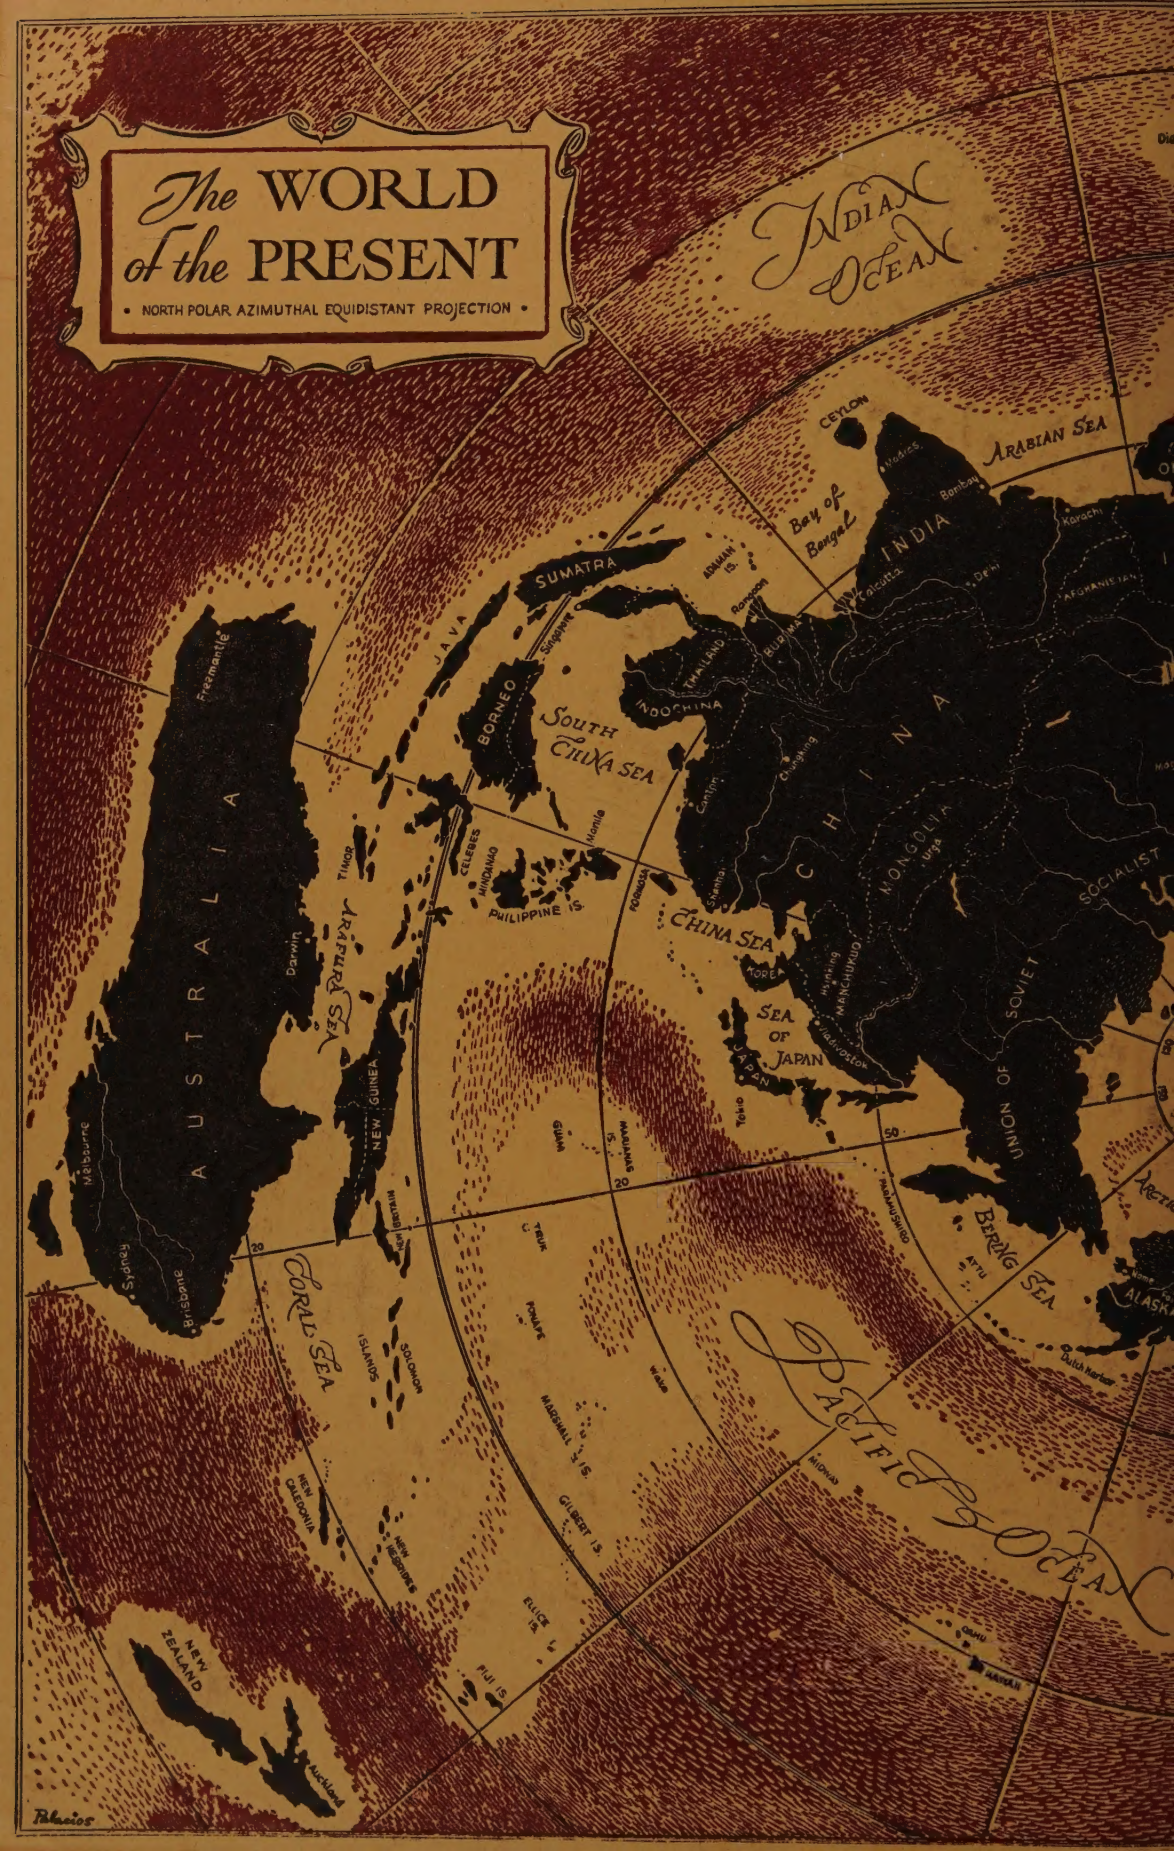
CORONEL, Battle of. A naval engagement fought 1 Nov. 1914 off the coast of Chile between a British squadron under Rear-Adm. Sir Christopher Cradock (q.v.) and the German Pacific squadron commanded by Admiral von Spee. Cradock's four vessels—two armored cruisers, one light cruiser and an armed liner—were no match in regard to speed and range for the German squadron of five vessels. The *Good Hope, Monmouth* and *Otranto* were sunk; only the light cruiser *Glasgow* escaped. Admiral Cradock went down with 1,650 officers and men. On 8 Dec. 1914 four vessels of von Spee's squadron were destroyed by the British off the Falkland Islands, and the fifth, the *Dresden,* was sunk off Juan Fernandez on 14 March 1915. See WAR, EUROPEAN — NAVAL OPERATIONS.

CORONER, a functionary whose name coroner, or crowner, implies that he has principally to do with pleas of the Crown or in which at least the Crown is concerned. His office is very ancient, mention being made of it in 925 A.D. His office in England was peculiarly a county institution. In Alfred's time he was appointed by the king, but since Edward I's time the office has been elective. His duties originally had to do with inquiries into fires and cases of wreckage and of sudden death, but now his court is a court of record in which, after sight of the body of one who has died in prison, or so suddenly that suspicions of violence may be excited, a jury summoned for the purpose pronounce a decision as to the cause of death. The proceedings under the auspices of the coroner prepare the way for a criminal prosecution. He also officiates as a sheriff's substitute when the sheriff himself is interested in a suit and cannot therefore act in it himself. In the United States the coroner is an elective county officer. His duties are similar to those of a coroner in England. Generally he has no right to inquire into the cause or origin of a fire except when death has resulted from it, but by statute in some States he has the power and duty to investigate the causes and origins of fires which appear to be of incendiary origin. Consult 'Encyclopedia of the Laws of England' (Vol. III, London 1897); Weinmann, G. H., 'Survey of the Law Concerning Dead Human Bodies' (1929); Smith, B. D., 'Powers, etc., of Coroners' (2d ed., Albany 1897); Jarvis, 'Office and Duties of Coroners with Forms and Precedents' (5th ed., London 1888); Boys, 'Treatise on Coroners' (Toronto 1893).

CORONETS. See CROWNS AND CORONETS.

CORONIS, (1) in Greek mythology, the daughter of King Phoroneus, whom Neptune loved, and who was changed into a crow by Athena whom she had begged for protection from Poseidon; (2) the daughter of Phelegyas and the mother of Asclepius.

CORONIUM, a hypothetical chemical element, supposed (by some astronomers) to exist in the sun. The evidence in favor of its existence consists in certain bright lines that are seen in the spectrum of the solar corona at the time of a total eclipse, and which are not known to be due to any recognized terrestrial element. On account of the great height above the sun's surface to which the matter that gives these lines extends, coronium has been assumed to be far lighter than hydrogen, which is the lightest known terrestrial element. Certain French and Italian scientists have reported the discovery of coronium in terrestrial volcanic gases; but their results need confirmation, and the existence of the supposed element, even in the solar atmosphere, has not yet been demonstrated. A line not very remote from the coronium line has been found in the spectrum of the aurora, so that certain scientists suppose that the upper layers of the earth's atmosphere contain a new element, geocoronium, much lighter than hydrogen.



The WORLD of the PRESENT
